Creates a collection containing the placement_attractions of the specified cells, ports, or placement_attraction shapes. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

Feedback

patterns

Matches the placement_attraction names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

`-at` *point*

Creates a collection that contains all placement_attractions at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all placement_attractions that are completely inside the specified region and doesn't include placement_attractions which are abut/touching from inside with the specified region. The region placement_attractionary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Feedback

`-touching` *region*

Creates a collection that contains all placement_attractions that are completely inside the specified region and the placement_attractions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all placement_attractions which are abut/touching from inside or outside to the specified region and the placement_attractions whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Feedback

Description

This command creates a collection of placement_attractions that meet the selection criteria. It returns a collection handle if one or more placement_attractions meet the selection criteria. If no attractions match the selection criteria, it returns an empty string.

You can use the *get_placement_attractions* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of placement_attractions by name pattern matching.

```
prompt> get_placement_attractions attract*
{"attract1", "attract2", "attract3"}
```

The following example creates a collection of placement_attractions with attribute filtering.

```
prompt> get_placement_attractions -filter {effort == medium}
{"attact1"}
```

The following example creates a collection of all placement_attractions.

```
prompt> get_placement_attaractions *
{"attract1", "attract2", "attract3", "attactA"}
```

The following example creates a collection of all placement_attaractions containing the cells "inv*" and port "reset".

```
prompt> get_placement_attaractions -of_objects "inv* reset"}
{"attract1", "attract2"}
```

See Also

- add_to_placement_attraction

Feedback

get_placement_blockages

Creates a collection of placement blockages from the current design.

Syntax

```
collection get_placement_blockages
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -at point
  | -within region
  | -touching region
  | -intersect region ]
```

Data Types

```
design          collection
expression      string
exact_count     integer
minimum_count   integer
patterns        list
point           list
region          list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with expression. For any placement blockages that match the *patterns* argument, the expression is evaluated based on the attributes of the placement blockages. If the expression evaluates to *true*, the placement blockage is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

Feedback

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for placement blockages level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*.

`patterns`

Specifies the placement blockages. The patterns can be a collection handle of blockages or other formats, similar to the following:

- * (asterisk) indicates all placement blockages
- *xx** indicates any placement blockage whose name begins with *xx*
- PB_77 indicates one placement blockage that does not yet have a name and its object_id is 77
- PB_* indicates any placement blockage that does not yet have a name.

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be

Feedback

specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all placement_blockages at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *`region`*

Creates a collection that contains all placement_blockages that are completely inside the specified region and doesn't include placement_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *`region`*

Creates a collection that contains all placement_blockages that are completely inside the specified region and the placement_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

Feedback

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all placement_blockages which are abut/touching from inside or outside to the specified region and the placement_blockages whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of placement blockages that meet the selection criteria. It returns a collection of placement blockages if one or more blockages meet the selection criteria. If no blockages match the selection criteria, it returns an empty string. You can use the *get_placement_blockages* command as an argument to another command or assign its result to a variable. Refer to the example below for details.

Feedback

You can use the *get_placement_blockages* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* man page for information about working with collections.

Examples

The following examples show some uses of this command to create placement blockages:

```
prompt> get_placement_blockages *
{"PB_1", "PB_2", "PB_3"}

prompt> get_placement_blockages * -filter "area > 1000"
{"PB_3"}
```

See Also

---

get_placement_ir_drop_target

Get placer IR drop targets

Syntax

string *get_placement_ir_drop_target voltage_area*

```
list voltage_area
```

Arguments

voltage_area

Specifies the voltage area for settings the IR drop targets

Description

This command returns the IR aware placement target voltage drops for the given voltage areas. The result is a list of IR drop targets, each IR drop target itself is a list of three or four items: the voltage area name; "low" or "high" to denote the voltage drop target type, the voltage drop target (in percentage) and optionally the word "-irdrop" if the target number is not a populastion percentage but a voltage drop percentage.

Feedback

Examples

The following example shows the use of *get_placement_ir_drop_target* command:

```
prompt> set_placement_ir_drop_target DEFAULT_VA low 1.0 -irdrop
prompt> set_placement_ir_drop_target DEFAULT_VA high 2.0
prompt> get_placement_ir_drop_target DEFAULT_VA
{ { DEFAULT_VA low 1.000000 -irdrop } { DEFAULT_VA high 2.000000 } }
```

See Also

- set_placement_ir_drop_target
- reset_placement_ir_drop_target
- report_placement_ir_drop_target

---

get_port

Creates a collection of ports from the current design. You can assign these ports to a variable or pass them into another command.

Syntax

collection *get_ports*

```
[-filter expression]
[-design design]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
  | [-of_objects objects]
  | [-assigned_to cells_and_pins]
  | [-at point]
  | [-within region]
  | [-touching region]
  | [-intersect region]
```

Data Types

```
expression      string
design          collection
exact_count     integer
minimum_count   integer
patterns        list
objects         list
```

Feedback

```
cells_and_pins list
point          list
region         list
```

Arguments

`-filter` *expression*

Filters the collection with *expression*. For any ports that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

`-design` *design*

Specifies the top design for finding the objects.If this option is not specified, the command includes the current design objects.

`-quiet`

Suppresses warning and error messages if no objects match. This option does not suppresses the syntax error messages.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This option is used when searching for the objects that contain the * and ? wildcard characters. *-exact* and *-regexp* options are mutually exclusive.

`-physical_context`

This option is needed when a cell object is provided as an input to *-of_objects* option. The ports of the cells are returned, if the cell is a physical hierarchical cell.

`-expect` *exact_count*

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

Feedback

`-expect_each_pattern_matches`

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns do not match, the command raises a Tcl error and stops.

`patterns`

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-of_objects` *`objects`*

Creates a collection of ports that are connected to or associated with the specified objects. Each object is a named cell, cell collection, named net, net collection, named port bus, port bus collection, named stub_chain, stub_chain collection, named scan_chain or scan_chain collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-assigned_to` *`cells_and_pins`*

Creates a collection of ports that are assigned to the specified pad cells or pad pins. The returned ports have terminals that use the shape of the pad pins. The terminals have an *is_owned_by_pad* attribute value of true.

`-at` *`point`*

Creates a collection that contains all ports at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-within` *`region`*

Creates a collection that contains all ports that are completely inside the specified region and does not include ports which are abut or touching from

Feedback

inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

`-touching` *region*

Creates a collection that contains all ports that are completely inside the specified region and the ports which are abut or touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the *-hierarchical* option with the *-touching* option.

`-intersect` *region*

Creates a collection that contains all ports which are abut or touching from inside or outside to the specified region and the ports whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Description

The *get_ports* command creates a collection of ports in the current design that match certain criteria. The command returns a collection if any ports match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, use rigid quoting with curly braces around regular expressions when you specify the *patterns* and filter *expression*. the regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as required.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching.

Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus port inclusively between the begin and end indexes. Note that the "[]" characters must be escaped, because they are Tcl special characters (for example, A\ \[0:15:2\\]).

Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth port inclusively between the begin and end indexes, which has a matching name without the delimiters characters (for example, port names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1.

Multiple "begin_index:end_index:step_n" patterns might be specified, separated with a ',' character.

You can use the *get_ports* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_ports* result to a variable.

When issued from the command prompt, *get_ports* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects

Feedback

are displayed; you can change this maximum number of object using the application option *shell.common.collection_result_display_limit*.

The "implicit query" property of *get_ports* provides a fast and simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_ports* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page. In addition, see *all_inputs* and *all_outputs* man pages, which also create collection of ports.

Examples

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
prompt> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

The following example queries ports using bus subscripting.

```
prompt> get_ports {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

The following example queries ports using name expansion subscripting.

```
prompt> get_ports B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example sets the driving cell for ports beginning with "in" to an FD2.

```
prompt> set_driving_cell -cell FD2 -library my_lib [get_ports in*]
```

The following example reports ports connected to nets matching the pattern "bidir*".

```
prompt> report_port [get_ports -of_objects [get_nets "bidir*"]]
```

Feedback

get_port_antenna_property

Get antenna attribute values on the specified port.

Syntax

```
antenna_prop_list get_port_antenna_property
-port    port
[-layer  pin_layer]

antenna_prop_list  collection
```

Data Types

```
port   blk port or lib-pin
layer  layer object
```

Arguments

`-port port`

Specify the port or lib_pin from which the antenna property is to be retrieved.

This option is required.

`-layer search_layer`

Specifies the layer only for which the antenna properties for the port will be returned.

If you do not specify this option, the tool will return all the antenna properties on all the layers. If you specify this option, only those antenna properties on the specified layer will be returned.

Description

This command gets antenna property data from the specified port or lib_pin. It returns the data as a Tcl array of the form:

```
{[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size
 gate_data
 mode1_area mode1_data mode2_ratio mode2_data mode3_area mode3_data
 mode4_area mode4_data mode5_ratio mode5_data mode6_area mode6_data}
```

In the event no layer is given, the data for all metal layers that have antenna data is returned in the following form (abbreviated here for clarity):

```
{
 {[well_type] [oxide_model <type>] metalLayer metalLayer1 gate_size
 gate_data1 ...}
 {[well_type] [oxide_model <type>] metalLayer metalLayer2 gate_size
 gate_data1 ...}
```

Feedback

```
 ...
}
```

Note that the returned data is a Tcl array and as such can be easily modified.

Returns

antenna_prop_list if successful, empty list otherwise

Examples

The following examples depict the behavior.

```
prompt> get_port_antenna_property -port p3 -layer metal3
{{metalLayer metal3 gate_size 0.3436 mode1_area 6.664
  mode2_ratio 2.05346 mode3_area 12.708 mode4_area 17.5392
  mode5_ratio 7.04044 mode6_area 12.682} {well1 metalLayer metal3
  gate_size 0.8436 mode1_area 7.164 mode2_ratio 2.55346 mode3_area
  13.208 mode4_area 18.0392 mode5_ratio 7.54044 mode6_area 13.182}}

prompt> get_port_antenna_property -port p3 -layer metal3
{}
```

See Also

- derive_hier_antenna_property
- set_port_antenna_property

---

get_port_buses

Creates a collection of port buses from the current design. You can assign these port buses to a variable or pass them into another command.

Syntax

collection *get_port_buses*

```
[-design design]
[-physical_context]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
patterns | -of_objects objects
```

Feedback

Data Types

design	string or collection
expression	string
exact_count	integer
minimum_count	integer
patterns	list
objects	string or collection

Arguments

`-design` *design_name*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

`-physical_context`

This option is needed when a cell object is provided as input to the *-of_objects* option. The port buses of the cells are returned, if the cell is a physical hierarchical cell.

`-filter` *expression*

Filters the collection with *expression*. For any port buses that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Specifies that the *patterns* argument is a real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. Use this option when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-of_objects` *`objects`*

Creates a collection of port buses connected to the specified objects. Each object is a named cell, cell collection, named port, port collection, named block or block collection. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

`patterns`

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching. *patterns* and *-of_objects* are mutually exclusive; you must specify one, but not both.

Description

The *get_port_buses* command creates a collection of port buses in the current design that match the specified criteria. The command returns a collection if any port buses match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the *regexp* Tcl command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_port_buses* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_port_buses* result to a variable.

When issued from the command prompt, *get_port_buses* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *shell.common.collection_result_display_limit* application option.

Feedback

The "implicit query" property of *get_port_buses* provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_port_buses* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page. In addition, refer to the man pages for *all_inputs* and *all_outputs*, which also create collections of port buses.

Examples

The following example queries all input port buses beginning with 'bus'. Although the output looks like a list, it is just a display.

```
prompt> get_port_buses "bus*"
{"bus1", "bus2"}
```

- filter_collection
- query_objects
- shell.common.collection_result_display_limit

---

get_ports

Creates a collection of ports from the current design. You can assign these ports to a variable or pass them into another command.

Syntax

collection *get_ports*

```
[-filter expression]
[-design design]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-physical_context]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
```

Feedback

```
  | [-of_objects objects]
  | [-assigned_to cells_and_pins]
  | [-at point]
  | [-within region]
  | [-touching region]
  | [-intersect region]
```

Data Types

```
expression     string
design         collection
exact_count    integer
minimum_count  integer
patterns       list
objects        list
cells_and_pins list
point          list
region         list
```

Arguments

`-filter expression`

Filters the collection with *expression*. For any ports that match *patterns*, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the cell is included in the result.

`-design design`

Specifies the top design for finding the objects.If this option is not specified, the command includes the current design objects.

`-quiet`

Suppresses warning and error messages if no objects match. This option does not suppresses the syntax error messages.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This option is used when searching for the objects that contain the * and ? wildcard characters. *-exact* and *-regexp* options are mutually exclusive.

Feedback

`-physical_context`

This option is needed when a cell object is provided as an input to *-of_objects* option. The ports of the cells are returned, if the cell is a physical hierarchical cell.

`-expect` *`exact_count`*

Specifies an exact number of objects to find. If the command finds a different number of objects, the command raises a Tcl error and stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, the command raises a Tcl error and stops.

`-expect_each_pattern_matches`

Ensures that each pattern in *patterns* matches at least one object. If one or more patterns do not match, the command raises a Tcl error and stops.

`patterns`

Matches port names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type port. Patterns can also include subscript patterns, but not in conjunction with wildcard and regular expressions pattern matching.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-of_objects` *`objects`*

Creates a collection of ports that are connected to or associated with the specified objects. Each object is a named cell, cell collection, named net, net collection, named port bus, port bus collection, named stub_chain, stub_chain collection, named scan_chain or scan_chain collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-assigned_to` *`cells_and_pins`*

Creates a collection of ports that are assigned to the specified pad cells or pad pins. The returned ports have terminals that use the shape of the pad pins. The terminals have an *is_owned_by_pad* attribute value of true.

Feedback

`-at` *point*

Creates a collection that contains all ports at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-within` *region*

Creates a collection that contains all ports that are completely inside the specified region and does not include ports which are abut or touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

`-touching` *region*

Creates a collection that contains all ports that are completely inside the specified region and the ports which are abut or touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the *-hierarchical* option with the *-touching* option.

`-intersect` *region*

Creates a collection that contains all ports which are abut or touching from inside or outside to the specified region and the ports whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Description

The *get_ports* command creates a collection of ports in the current design that match certain criteria. The command returns a collection if any ports match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, use rigid quoting with curly braces around regular expressions when you specify the *patterns* and filter *expression*. the regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as required.

Subscript patterns are also supported, but cannot be used in conjunction with wildcard or regular expression pattern matching.

Bus subscripting is specified with the format "name[begin_index:end_index:step_n]", and returns every nth bus port inclusively between the begin and end indexes. Note that the "[]" characters must be escaped, because they are Tcl special characters (for example, A\ \[0:15:2\\]).

Feedback

Name expansion subscripting is specified with the format "name(begin_index:end_index:step_n)", and returns every nth port inclusively between the begin and end indexes, which has a matching name without the delimiters characters (for example, port names do not actually contain the '(' and ')' characters). Note that ":step_n" is optional. The default step is 1.

Multiple "begin_index:end_index:step_n" patterns might be specified, separated with a ',' character.

You can use the *get_ports* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_ports* result to a variable.

When issued from the command prompt, *get_ports* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects are displayed; you can change this maximum number of object using the application option *shell.common.collection_result_display_limit*.

The "implicit query" property of *get_ports* provides a fast and simple way to display cells in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_ports* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page. In addition, see *all_inputs* and *all_outputs* man pages, which also create collection of ports.

Examples

The following example queries all input ports beginning with 'mode'. Although the output looks like a list, it is just a display.

```
prompt> get_ports "mode*" -filter {direction == in}
{"mode[0]", "mode[1]", "mode[2]"}
```

The following example queries ports using bus subscripting.

```
prompt> get_ports {A[0:1,3:7:2]}
{"A[0]", "A[1]", "A[3]", "A[5]", "A[7]"}
```

The following example queries ports using name expansion subscripting.

```
prompt> get_ports B(0:4:2)C(1:2,5)
{"B0C1", "B0C2", "B0C5", "B2C1", "B2C2", "B2C5",
 "B4C1", "B4C2", "B4C5"}
```

The following example sets the driving cell for ports beginning with "in" to an FD2.

```
prompt> set_driving_cell -cell FD2 -library my_lib [get_ports in*]
```

The following example reports ports connected to nets matching the pattern "bidir*".

Feedback

```
prompt> report_port [get_ports -of_objects [get_nets "bidir*"]]
```

- shell.common.collection_result_display_limit

---

get_power_budget

Returns the power budget for either the current design or a list of cells in the current design.

Syntax

status *get_power_budget*

```
[-scenarios scenario_list]
[-cell cell_list]
```

Data Types

```
scenario_list     list
cell_list         list
```

Arguments

`-scenarios scenario_list`

Indicates the scenario for which the budget values are returned. If no scenario is specified the current_scenario is used.

`-cell cell_list`

Specifies a list of cells on which the power budget values are reported.

Description

This command is used to return the budget values either on the design or on specific cells in the design. If this command is called without any option, the power budget value for the current design is returned.

If the command is called with the -cell option, then budget values will only be reported for the instances specified in the cell list.

Feedback

Returns the requested numbers as a tagged list.

Examples

In the following example, power budget value has been set globally on the design.

```
prompt> set_power_budget 5.92e+05
prompt> get_power_budget

{{Scenario SC1} {Design Top} {Power_Budget 5.92e+05}}
```

In the following example power budget has been set globally on the design, as well as on the hierarchical cell H1/H2.

```
prompt> set_power_budget 3.9e+05
prompt> set_power_budget -cell [get_cell H1/H2] 2.3e+03
prompt> get_power_budget [get_cells H1/H2]

{{Scenario SC1} {Cell H1/H2} {Power_Budget 2.3e+03}}
```

See Also

- get_power_budget
- reset_power_budget
- report_power_budget
- report_power

---

get_power_clock_scaling

Returns the clock frequency scaling values stored.

Syntax

status *get_power_clock_scaling*

```
[-scenarios scenarios]
[clock_list]
```

Data Types

```
scenarios        list
clock_list        list
```

Arguments

`-scenarios` *scenarios*

Specify a list of scenarios for which the scaling factor is to be retrieved, if found. If not specified, then scaling data is filtered for only the clock

Feedback

objs specified through clock_list option. If both scenarios and clocks are not specified then complete scaling data is printed. If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this option can take atmost one value. If the app option is set to true, and if this option is not used, the current scenario is assumed.

`clock_list`

Specify a list of clocks in the design for which the scaling factor is to be retrieved, if found. If not specified, then scaling data is filtered for only the scenarios specified through -scenarios option. If both scenarios and clocks are not specified then complete scaling data is printed. If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this option can take atmost one value. If the app option is set to true, and if this option is not used, the non-clock specific ratio value will be returned for the scenario.

Description

Clock frequency used in Switching Activity Interchange Format (SAIF) files, from logic simulation for functional verification can differ from the clock frequency used in Synopsys Design Constraints (SDC) file for timing and power analysis. This command retrieves the scaling factors stored in the set_power_clock_scaling command.

The clock_objects option in this command is a list of clocks in the design that have the specified period or ratio values used in simulation for SAIF generation. The scenarios are the ones for which the scaling factors are to be retrieved and displayed. Note that if both the scenario and the clock options are not specifed then the complete scaling data for all the scenarios is displayed.

When period value is specified for a clock, then the scaling ratio is calculated as the ratio of (period of the clock from set_power_clock_scaling cmd) / (period of the fastest clock of an object).This ratio is applied to the retrieved simulated activity of the object. If the ratio value is specified then it is directly applied as the scaling ratio.This ratio is applied to the retrieved simulated activity of the object.

If the app option power.get_power_clock_scaling_single_objects_only is set to 'true', this command will return only a tuple containing the scaling value. The value returned will be clock specific value if clock is specified and will be global ratio value if clock is not specified. If the scenario option is not specified & the app option is true, the current scenario is assumed for fetching the tuple.

Examples

The following examples describe the behaviour of the cmd.

```
prompt> set_power_clock_scaling {CLK CLK2 C_A} -period 2.6
prompt> set_power_clock_scaling -ratio 1
prompt> get_power_clock_scaling
------------------------------------------------------------------
```

Feedback

```
         Clock Scaling Data
-------------------------------------------------------------
Scenario:default, Clock name:CLK, Period:2.600000
Scenario:default, Clock name:CLK2, Period:2.600000
Scenario:default, Clock name:C_A, Period:2.600000
-------------------------------------------------------------
Scaling Ratios for Scenarios without Clocks
-------------------------------------------------------------
Scenario:default, Ratio:1.000000
```

See Also

- set_power_clock_scaling
- report_power_clock_scaling
- power.get_power_clock_scaling_single_objects_only

---

get_power_derate

Returns the power derating factors for either the current design, a list of cells, library cells or all cells in a power group in the current design.

Syntax

status *get_power_derate*

```
[-scenarios scenario_list]
[-leakage]
[-switching]
[-internal]
[-user]
[object_list]
```

Data Types

scenario_list	list
object_list	list

Arguments

`-scenarios` *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

`-leakage`

Returns the leakage specific derating values only.

`-switching`

Returns the switching specific derating values only.

Feedback

`-internal`

Returns the internal specific derating values only.

`-user`

Returns the actually stored power derating attributes if and only if they exist.

`object_list`

Specifies current a list of cells or library cells on which the power derating factors are reported.

Description

This command is used to return the derate factors either on the design, specific cells or library cells contained in the design. If this command is called without any option the current design power derating factors are returned.

If this command is called with option -user it will return the actually stored attributes if and only if they exist. Without -user, the command will return the used (inherited) derating factors. If the command is called with the object_list specified then derating factors will only be issued for the instances specified in the object list.

Returns requested numbers as a tagged list. If none of -leakage, -internal or -switching is specified it returns all three.

Examples

In the following example, power derating factors have been set globally on the design.

```
prompt> set_power_derate -switching 0.92
prompt> set_power_derate -internal 1.15
prompt> set_power_derate -leakage 0.75
prompt> get_power_derate

{ {scenario default} {object Top} {leakage 0.75} {switching 0.92 }
 {internal 1.15 } }
```

In the following example power derating factors have been set globally on the design. More restrictive derates have been set on the hierarchical cell H1.

```
prompt> set_power_derate 0.95
prompt> set_power_derate -switching 1.06
prompt> set_power_derate -internal -leakage 0.82 [get_cell H1]
prompt> get_power_derate [get_cells H1/U1]

{ {scenario default} {object H1/U1} {leakage 0.82 } {switching 1.06}
 {internal 0.82 } }
```

In the following example only the power derating factors set specifically by the user are returned for the hierarchical cell H1.

Feedback

```
prompt> get_power_derate -user [get_cells H1/U1]

{ {scenario default} {object H1/U1} {leakage 0.82 } {internal 0.82 } }
```

See Also

- get_power_derate
- reset_power_derate
- report_power_derate

---

get_power_domains

Creates a collection of power domains that meet the specified criteria.

Syntax

collection *get_power_domains*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects objects]
[patterns]
```

Data Types

expression	string
exact_count	int
minimum_count	int
objects	list
patterns	list

Arguments

`-hierarchical`

Searches for power domains in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for power domains only in the current scope and you can use hierarchy delimiter characters in the *patterns*

Feedback

argument to specify hierarchical power domain names relative to the current scope.

You cannot specify this option when you use the *-of_objects* option.

`-filter` *`expression`*

Filters the collection with *expression*. For any power domains that match *patterns*, the expression is evaluated based on the power domain's attributes. If the expression evaluates to true, the power domain is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Returns a collection of power domains associated with the specified objects. The objects can be cells, power strategies, voltage areas, or voltage area shapes.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

Feedback

patterns

Matches power domain names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses "*".

Description

The *get_power_domains* command creates a collection of power domains in the current design that match certain criteria. If no power domains match the criteria, an empty string is returned.

Until the *commit_upf* command is executed and power intent is finalized, power domains of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using *-regexp*, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_power_domains* command at the command prompt, or you can nest it as an argument to another command, such as *report_power_domains*. In addition, you can assign the *get_power_domains* result to a variable.

When issued from the command prompt, *get_power_domains* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates power domains, then queries them.

```
prompt> create_power_domain TOP_DOMAIN
1
prompt> create_power_domain SUB_DOMAIN -elements [get_cells mid1]
1
prompt> get_power_domains
{TOP_DOMAIN SUB_DOMAIN}
prompt> get_power_domains TOP*
{TOP_DOMAIN}
```

The following example gets all power domains under the current scope.

Feedback

```
prompt> get_power_domains -hierarchical
{PD1 SUB_INST/PD2}
```

See Also

- create_power_domain
- report_power_domains

---

get_power_group

Returns list of all power groups the specified cell or libcell is in.

Syntax

status *get_power_group*

```
object
[-user]
[-default]
```

Data Types

object	object

Arguments

`-user`

Returns user specified power groups for the specified *object* if exist, else an error message is reported stating no user specified power group found on that object.

`-default`

Returns default power group for the specified *object*.

object

Specifies cell or libcell for which power group needs to be reported.

Description

This command returns list of all power groups on the specified object. If '-user' is specified then user specified power groups are reported. If '-default' is specified then default power group is reported. If neither '-user' nor '-default' is specified then return value depends on the app option 'power.report_user_power_groups'. If the app option is set as 'exclusive' then command returns Actual power group. Actual power group is the user specified power group present for that cell. If multiple user power groups are specified then first power group in the specified list is Actual power group. If user specified power group is not present for that cell then actual power group is the user specified power group present

Feedback

for the libcell of that cell. If multiple user power groups are present for the libcell then first power group in the specified list is Actual power group. If user specified power group is not present for that libcell then actual power group is the default power group of that cell. If app option value is 'inclusive' then list of all user specified power groups and default power group of that cell is returned. If cell has no user power groups specified then the corresponding libcell is checked for user specified power groups. It is to be noted that '-user' and '-default' options can not be specified together.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example returns default power group of a cell.

```
prompt> get_power_group u3/S_reg_0 -default
```

See Also

- set_power_group
- reset_power_group
- report_power_groups
- get_power_group_objects
- report_power
- power.report_user_power_groups

---

get_power_group_objects

Returns a collection of cells for the specified power groups.

Syntax

status *get_power_group_objects*

```
        group_names
```

Data Types

group_names	list

Feedback

Arguments

group_names

Specifies the power groups for which the collection of cells will be returned.

Description

The get_power_group_objects command returns a collection of cells contained by the specified power groups. The return value depends on app option 'power.report_user_power_groups'. The collection will have no duplicate objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example returns collection of cells present in power group macro1 and register.

```
prompt> get_power_group_objects {macro1 register}
```

See Also

- set_power_group
- reset_power_group
- get_power_group
- report_power_groups
- report_power
- power.report_user_power_groups

---

get_power_strategies

Creates a collection of power strategies.

Syntax

collection *get_power_strategies*

```
[-domain power_domain]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
```

Feedback

```
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects objects]
[patterns]
```

Data Types

```
power_domain    string
expression      string
exact_count     integer
minimum_count   integer
patterns        list
```

Arguments

`-domain power_domain`

Specifies the name of the power domain in which to collect this UPF power strategy.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the power strategies attributes. You can determine the power strategies attributes by using the *list_attributes* command. If the expression evaluates to *true*, the power strategy is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-of_objects` *`objects`*

Returns a collection of power strategies associated with the specified objects. The objects can be cells or power domains.

`patterns`

Matches the power strategy names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument is not specified, the command uses asterisk (*) as the *pattern*.

Description

This command creates a collection of power strategies that match certain criteria. The command returns a collection handle (identifier) if any power strategies match the value of the *patterns* option and pass the filter criteria (if specified). If no objects match the criteria, the command returns an empty string.

Until the *commit_upf* command is executed and power intent is finalized, strategies of subblocks are not propagated and are not included in the result.

You can use the *get_power_strategies* command at the command prompt or nest it as an argument to another command (such as *get_cells*, *set_power_strategy*). You can also assign the *get_power_strategies* result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following returns isolation strategies defined in specified power domain.

```
prompt> get_power_strategies -domain TOP -filter {type==ISO}
{iso_stra1 iso_stra2}
```

Feedback

See Also

- create_power_switch
- set_isolation
- set_level_shifter
- set_power_strategy_attribute
- set_retention

---

get_power_switch_patterns

Creates a collection of power switch patterns that meet the specified criteria.

Syntax

collection *get_power_switch_patterns*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
```

Data Types

```
expression      string
exact_count     int
minimum_count   int
objects         list
patterns        list
```

Arguments

`-filter expression`

Filters the collection with *expression*. For any power switch patterns that match *patterns*, the expression is evaluated based on the attributes of the power switch pattern. If the expression evaluates to true, the power switch pattern is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

Feedback

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`patterns`

Matches power switch pattern names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

Description

The *get_power_switch_patterns* command creates a collection of power switch patterns in the current design, that match certain criteria. If no power switch pattern match the criteria, an empty string is returned.

Regular expression matching is the same as in the Tcl regexp command. When using *-regexp*, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_power_switch_patterns* command at the command prompt, or you can nest it as an argument to another command, such as *report_power_switch_patterns*. In addition, you can assign the *get_power_switch_patterns* result to a variable.

Feedback

When issued from the command prompt, *get_power_switch_patterns* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by setting the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example gets all power switch patterns in the current design.

```
prompt> get_power_switch_patterns
{PSW_PATTERN_INST_pattern2_0 PSW_PATTERN_INST_pattern2_1
 PSW_PATTERN_INST_pattern2_2}
```

The following example gets all power switch patterns matching a given pattern.

```
prompt> get_power_switch_patterns *pattern2_7*
{PSW_PATTERN_INST_pattern2_7 PSW_PATTERN_INST_pattern2_70
 PSW_PATTERN_INST_pattern2_71}
```

See Also

- report_power_switch_patterns

---

get_power_switch_resistance

Get the currently specified Ron setting.

Syntax

status *get_power_switch_resistance*

```
collection_of_lib_cells
```

Data Types

collection_of_lib_cells string

Arguments

collection_of_lib_cells

The name of the collection of lib cells.

Description

This command gets the currently Ron setting which specifying by *set_power_switch_resistance* command

Feedback

Examples

```
prompt> get_power_switch_resistance saed32hvt_pg_ss0p_v125c/HEAD2X2_HVT
```

See Also

- get_power_switch_resistance
- size_power_switches
- set_power_switch_resistance
- reset_power_switch_resistance
- report_power_switch_resistance

---

get_power_taps

Returns the power tap cells for either the current design or a list of clock nets or a shape in the current design.

Syntax

status *get_power_taps*

```
[-nets net_list]
[-shape hield_shape_name]
```

Data Types

```
list of clock nets list
shape              string
```

Arguments

`-nets net_list`

Indicates the clock nets for which the tap cells are returned. If no net is specified, all clock nets in design are used.

`-shape shape_name`

Specifies a shield shape name for which the power tap cells are fetched.

Description

This command is used to return the tap cells either for clock nets or for specific shield shape in the design. If this command is called without any option, the power tap cells for all clock nets in the current design are returned.

If the command is called with the -shape option, then tap cells will only be reported for specified shield shape.

Feedback

Examples

In the following example, power tap cells have been inserted at every 10u on the shield shapes of clock net CLK. , and the get_power_taps command is used to fetch all the power tap cells inserted in the design as Tcl list.

```
prompt> insert_power_tap_cells -lib_cells [get_lib_cells */INVGX8M] -nets
  [get_nets CLK] -tap_frequency 10
prompt> get_power_taps

{cdu_dlvrl/gnd_shield_PTAP_H_41540 cdu_dlvrl/gnd_shield_PTAP_H_41541}
```

See Also

- insert_power_tap_cells
- report_power_taps
- remove_power_taps

---

get_pr_rules

Returns a collection of cell row spacing rules (pr_rules) from the specified technology object.

Syntax

```
collection get_pr_rules
[-tech tech_object]
[-library library]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[patterns]
```

Data Types

tech_object	collection
library	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list
patterns	string

Feedback

Arguments

`-tech` *`tech_object`*

Specifies the technology object in which to search for the cell row spacing rules.

The *-tech* and *-library* options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is searched in the technology object of the current library.

`-library` *`library`*

Specifies the library in which to search for the cell row spacing rules. The command searches for the rules in the technology object associated with the specified library. In an implementation tool, the library is a design library. In the library manager, the library is a cell library. You can specify the library using the library's name or a collection that contains the library.

The *-tech* and *-library* options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is searched in the technology object of the current library.

`-filter` *`expression`*

Filters the collection with *expression*. For any rules that match the *patterns* or *objects* option, the expression is evaluated based on the attributes of the rule. If the expression evaluates to true, the rule is included in the result.

`-quiet`

Suppresses warning and error messages if no object matches. Syntax error messages are not suppressed.

`-regexp`

Considers the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The *-regexp* and *-exact* options are mutually exclusive; you can specify only one.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

Feedback

The *-regexp* and *-exact* options are mutually exclusive; you can specify only one.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, it raises a Tcl error and stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, it raises a Tcl error and stops.

`-expect_each_pattern_matches`

Requires each pattern in the *patterns* argument to match at least one object. If one or more patterns do not match, the command raises a Tcl error and stops.

`-of_objects` *`of_objects`*

Creates a collection that contains the cell row spacing rules of the specified technology objects. Each object in the list is a name, pattern, or collection.

The *-of_objects* option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

`patterns`

Matches the rule names against the *patterns* argument. The *patterns* argument can include the "*" wildcard character.

The *-of_objects* option and *patterns* argument are mutually exclusive; you can specify only one. If you do not specify either, the wildcard "*" is used as the *pattern*.

Description

The *get_pr_rules* command creates a collection of cell row spacing rules from the specified technology object that match certain criteria. The rules include both the rules specified in the PRRule section of the technology file and the rules created with the *create_pr_rule* command.

The command returns a collection of rules if at least one cell row spacing rule matches the criteria; otherwise, it returns an empty string.

You can use the *get_pr_rules* command at the command prompt or nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_pr_rules* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Examples

The following example returns a collection that contains all the cell row spacing rules in the technology object of the current library.

```
prompt> get_pr_rules
{PR_RULE_0}
```

See Also

- create_pr_rule
- remove_pr_rules
- report_pr_rules

---

get_process_layers

Creates a collection of process_layers.

Syntax

status *get_process_layers*

```
[patterns]
[-of_objects libraries]
[-filter expression]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect count]
[-expect_at_least count]
[-expect_each_pattern_matches]
```

Data Types

patterns	string
libraries	collection
expression	string
count	integer

Arguments

patterns

Finds process layers with names matching these patterns.

-of_objects *libraries*

Specifies the libraries in which to find the process layers.

By default, the tool finds objects in the current library.

Feedback

`-filter` *expression*

Filters collection with *expression*.

`-quiet`

Does not print any messages.

`-regexp`

Specifies that patterns are full regular expressions.

`-exact`

Specifies that wildcards are considered as plain characters.

`-nocase`

Performs case-insensitive matching.

`-expect` *count*

Expects exactly these many matching objects: count >= 0.

`-expect_at_least` *count*

Expects at least these many matching objects: count >= 1.

`-expect_each_pattern_matches`

Specifies that each pattern must match at least one object.

Description

This command finds and creates a collection of process layers based on the options and filters specified. If no options are specified, it returns all the process layers of the current library.

Examples

The following example creates a collection of process_layer objects based on given pattern with case insensitive matching.

```
prompt> get_process_layers -nocase process_layer_*
```

See Also

- create_process_layer
- remove_process_layers
- report_collection

Feedback

get_pseudo_bumps

Creates a collection by selecting the pseudo bumps from the current block.

Syntax

collection *get_pseudo_bumps*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-index_range {col row} | {{col_ll row_ll} {col_ur row_ur}}]
[patterns
  | -of_objects of_objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
point           list
region          list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the pseudo bump attributes. You can determine the pseudo bump attributes by using the *list_attributes* command. If the expression evaluates to *true*, the pseudo bump is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

Feedback

`-design` *design_name*

Specifies the design module in which to search for the pseudo bumps.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for pseudo bumps level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`-index_range {col row} | {{col_ll row_ll} {col_ur row_ur}}`

Returns pseudo bumps with the specified index or index range (inclusive).

It is an error to use this option along with the following options: *-hierarchical*, *-at*, *-within*, *-touching*, *-intersect*, or *patterns*.

`-of_objects` *of_objects*

Creates a collection containing the pseudo bumps that are associated with the specified objects. Valid object types for the specified objects are *pseudo_bump_pattern* and *pseudo_bump*.

Each object in the list is a name, pattern, or collection.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

patterns

Matches the pseudo bump names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all the pseudo bumps at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

By default, query is limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all pseudo bumps that are completely inside the specified region and does not include pseudo bumps which are abut or touching from inside with the specified region. The region boundary can be rectangle or polygon.

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

Feedback

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all pseudo bumps that are completely inside the specified region and the pseudo bumps which are abut or touching from inside with the specified region. The region boundary can be rectangle or polygon.

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  `{{llx lly} {urx ury}}`

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  `{{x1 y1} {x2 y2} ... {xn yn}}`

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive. You can specify only one except *-within* and *-intersect* options that can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all pseudo bumps which are abut or touching from inside or outside to the specified region and the pseudo bumps whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

Feedback

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of pseudo bumps that meet the selection criteria. It returns a collection handle if one or more pseudo bumps meet the selection criteria. If no pseudo bumps match the selection criteria, it returns an empty string.

You can use the *get_pseudo_bumps* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of pseudo bumps by matching the name against the pattern:

```
prompt> get_pseudo_bumps BRPB0_2_*
{BRPB0_2_0 BRPB0_2_1 BRPB0_2_2}
```

See Also

- create_bump_region
- create_bump_region_pattern

Feedback

- get_bump_regions

---

get_pseudo_tsv_defs

Creates a collection by selecting pseudo_tsv definitions from the current block.

Syntax

collection *get_pseudo_tsv_defs*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the pseudo_tsv_def attributes. You can determine the pseudo_tsv_def attributes by using the *list_attributes* command. If the expression evaluates to *true*, the pseudo_tsv_def is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design design_name`

Specifies the design module in which to search for the pseudo_tsv_defs.

Feedback

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for pseudo_tsv_defs level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the pseudo_tsv_def names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the pseudo_tsv_defs that are associated with the specified objects. Valid object types for the specified objects are bump_region, pseudo_bump, and pseudo_tsv.

Each object in the list is a name, pattern, or collection.

Feedback

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Description

This command creates a collection of pseudo_tsv_defs that meet the selection criteria. It returns a collection if one or more pseudo_tsv_defs meet the selection criteria. If no pseudo_tsv_defs match the selection criteria, it returns an empty string.

You can use the *get_pseudo_tsv_defs* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of pseudo_tsv_defs by matching the name against the pattern:

```
prompt> get_pseudo_tsv_defs def*
{def0 def1 def2}
```

See Also

- create_pseudo_tsv_def
- remove_pseudo_tsv_defs
- create_bump_region
- get_bump_regions
- get_pseudo_tsvs

---

get_pseudo_tsvs

Creates a collection by selecting pseudo_tsvs from the current block.

Syntax

collection *get_pseudo_tsvs*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
```

Feedback

```
[-hierarchical]
[-index_range {col row} | {{col_ll row_ll} {col_ur row_ur}}]
[patterns
  | -of_objects of_objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the pseudo_tsv attributes. You can determine the pseudo_tsv attributes by using the *list_attributes* command. If the expression evaluates to *true*, the pseudo_tsv is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design design_name`

Specifies the design module in which to search for the pseudo_tsvs.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for pseudo_tsvs level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`-index_range {col row} | {{col_ll row_ll} {col_ur row_ur}}`

Returns pseudo_tsvs with the specified index or index range (inclusive).

It is an error to use this option along with the following options: *-hierarchical*, *-at*, *-within*, *-touching*, *-intersect*, or *patterns*.

`patterns`

Matches the pseudo_tsv names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

`-of_objects` *`of_objects`*

Creates a collection containing the pseudo_tsvs that are associated with the specified objects. Valid object types for the specified objects are *bump_region*, *pseudo_bump*, and *pseudo_tsv_def*.

Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

Feedback

`-at` *point*

Creates a collection that contains all the pseudo_tsvs at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

By default, query is limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all pseudo_tsvs that are completely inside the specified region and does not include pseudo_tsvs which are abutting or touching from inside with the specified region. The region boundary can be rectangle or polygon.

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all pseudo_tsvs that are completely inside the specified region and the pseudo_tsvs which are abutting or touching from inside with the specified region. The region boundary can be rectangle or polygon.

Feedback

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive. You can specify only one except *-within* and *-intersect* options that can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all pseudo_tsvs which are abutting or touching from inside or outside to the specified region and the pseudo_tsvs whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

  A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* options are mutually exclusive. You can specify only one, except *-within* and *-intersect* options can be specified together. If you do not specify any of these options, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query is limited to the current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of pseudo_tsvs that meet the selection criteria. It returns a collection if one or more pseudo_tsvs meet the selection criteria. If no pseudo_tsvs match the selection criteria, it returns an empty string.

You can use the *get_pseudo_tsvs* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of pseudo_tsvs by matching the name against the pattern:

```
prompt> get_pseudo_tsvs br0_*
{br0_PTSV_0_0 br0_PTSV_0_1 br0_PTSV_1_0 br0_PTSV_1_1}
```

See Also

- create_pseudo_tsv_def
- remove_pseudo_tsv_defs
- create_bump_region
- get_bump_regions
- get_pseudo_tsv_defs

---

get_purposes

Creates a collection of one or more purposes.

Syntax

```
collection get_purposes
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects of_objects]
```

Feedback

Data Types

expression	string
exact_count	int
minimum_count	int
of_objects	list
patterns	string

Arguments

`-filter` *expression*

Filters the collection with the value of *expression*. For any purposes that match, the expression is evaluated based on the layer's attributes. If the expression evaluates to true, the layer is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

Feedback

`-of_objects` *`of_objects`*

Creates a collection containing the purposes of the specified libs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches layer names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark) or regular expressions, depending on whether or not you also use the *-regexp* option.

Description

This command creates a collection of purposes defined in the technology file for the current library.

You can use the *get_purposes* command at the command prompt or as an argument nested in another command (for example, in the *query_objects* command). You can also assign its result to a variable.

The layer name printed for returned collection will have following format.

layer_name:purpose_name

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a layer for the name M1R.

```
prompt> get_purposes M1R
{drawing}
```

---

get_rail_probes

Prints probes in lisp format.

Feedback

Syntax

status *get_rail_probes* [-die *die_name*]

Data Types

die_name string

Arguments

-die

Prints probes by die.

Description

Prints probes in lisp format.

EXAMPLE

The following example prints probes in lisp format.

```
prompt> get_rail_probes
{{DIE soc_die_inst {REGION x1 y1 x2 y2}} {CELL uBUMP} {LAYER MB} {NET
 {VDD 80}}}
{{DIE soc_die_inst {REGION x1 y1 x2 y2}} {SIDE upper} {LAYER VIA1} {NET
 {VDD 80}}}
```

See Also

- analyze_rail
- set_rail_probes
- get_rail_probes
- reset_rail_probes

---

get_related_supply_nets

Creates a collection of related supply nets of signal pins or ports.

Syntax

collection *get_related_supply_nets*

```
[-filter expression]
[-quiet]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expand]
[-ground]
```

Feedback

```
[-in_block_upf]
objects
```

Data Types

```
expression    string
exact_count   int
minimum_count int
objects       list
```

Arguments

`-filter` *expression*

Filters the collection with *expression*. For each related supply net, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expand`

Do not merge and combine duplicated related supply nets of signal pins.

`-ground`

Specifies that the ground supply net should be returned.

`-in_block_upf`

This is for boundary ports of linked blocks only. Return the related supply net in block UPF. The return value shows the related supply net for this block boundary port when the linked block is opened as current block.

objects

Returns a collection of related supply nets associated with the signal pins or ports.

Feedback

Description

The *get_related_supply_nets* command creates a collection of related supply nets of the specified collection of pins or ports. Power supply net is returned by default. If the -ground option is specified, ground supply net is returned.

Until commit_upf command is executed and power intent is finalized, power intent of subblocks are not propagated and will not be included in the result.

Examples

The following example gets the related supply nets of all pins of a level-shifter cell.

```
prompt> get_related_supply_nets [get_pins Multiplier/mult_on_UPF_LS/*]
{VDDL}
```

See Also

- create_supply_net
- connect_supply_net
- set_related_supply_net

---

get_related_supply_set

Creates a collection of related supply sets of signal pins or ports.

Syntax

collection *get_related_supply_set*

```
[-quiet]
objects
```

Data Types

objects	list

Arguments

`-quiet`

Suppresses warning and error messages if no objects match or if related supply set cannot be resolved for a port or pin. Syntax error messages are not suppressed.

objects

list of pins or ports from which the returned collection of supply sets is generated.

Feedback

Description

The *get_related_supply_set* command creates a collection of related supply sets from the specified collection of pins or ports.

For each given pin/port, the returned supply set corresponds to any available supply set on its parent domain in which the power and ground functions resolve to the related power and ground supplies of the pin/port.

Until commit_upf command is executed and power intent is finalized, power intent of sub blocks are not propagated and are not included in the result.

Examples

The following example gets the related supply sets of a list of references of pins and top-level ports.

```
prompt>  get_related_supply_set {out_port macro/in}
{TOP_SS MACRO_SS}
```

See Also

- create_supply_set
- associate_supply_set

---

get_repeater_group_info

Get detailed information for input repeater group.

Syntax

```
status get_repeater_group_info
-group_id group_id
-type cutline | driver_group_id | path_drivers | path_loads | cells
```

Data Types

```
group_id                integer
```

Arguments

`-group_id group_id`

Specifies the group id set by set_repeater_group.

`-type`

Specifies the type to query.

Feedback

Description

This command gets detailed information for input repeater group.

Examples

The following examples show the usages of command.

```
prompt> get_repeater_group_info -group_id 4 -type driver_group_id
prompt> get_repeater_group_info -group_id 4 -type cutline
```

See Also

- set_repeater_group
- report_repeater_groups

---

get_repeater_paths_info

Get all repeaters on related paths for input cells or repeater groups.

Syntax

```
status get_repeater_paths_info
-cells cell_list |
  -repeater_groups group_id_list
[-verbose]
```

Data Types

```
cell_list                collection
group_id_list            list
```

Arguments

`-cells cell_list`

Specifies list of repeaters to query. The two options -cells and -repeater_groups are mutually exclusive, and one of them is required.

`-repeater_groups group_id_list`

Specifies list of repeater group ids to query. The two options -cells and -repeater_groups are mutually exclusive, and one of them is required.

`-verbose`

Reports related repeater paths info.

Description

This command gets all repeaters on related paths for input cells or repeater groups. It will find paths based on cell attribute group_repeater_driver and group_repeater_loads.

Feedback

And return list of collection of cells on paths which include the input cells or cells in input repeater group. The order of cells in collection for one path honors DFS (Depth First Search) traversal from driver to loads.

Examples

The following examples show the usages of command.

```
prompt> get_repeater_paths_info -cells [get_cells {eco_cell_3
 eco_cell_7}]
prompt> get_repeater_paths_info -repeater_groups {1 2 3 4 5}
```

See Also

- set_repeater_group
- report_repeater_groups

---

get_routes_between_objects

Returns net shapes that connect two ports or pins on the same net.

Syntax

status *get_routes_between_objects*

```
[-quiet]
[object_list]
```

Data Types

object_list collection or selection

Arguments

object_list

Specifies a collection or selection set that contains objects to get routes between. If this option is not specified, global selection set is used.

-quiet

Suppresses all output messages.

Description

This command returns a collection of net shapes that connect two ports or pins on the same net.

If the selection contains two objects of port or leaf pin on the same net, and the two objects are physically connected by routes of the net, this command returns a collection

Feedback

of net shapes that connect these two objects. Otherwise the command returns an empty collection.

Examples

The following example selects routes that connect the two leaf pins A0_12__reg/Q and RES_I109/ADD_6/A1.

```
prompt> change_selection [get_pins {A0_12__reg/Q RES_I109/ADD_6/A1} ]
prompt> change_selection [get_routes_between_objects]
```

The alternative syntax uses collection to specify objects.

```
prompt> change_selection [get_routes_between_objects [get_pins
 {A0_12__reg/Q RES_I109/ADD_6/A1} ] ]
```

See Also

- change_selection
- get_selection

---

get_routing_blockages

Creates a collection of routing blockages from the current design.

Syntax

```
collection get_routing_blockages
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_lib_cell]

[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Feedback

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list
patterns	string
region	list
point	list

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any routing blockages that match *patterns*, the expression is evaluated based on the routing blockage's attributes. If the expression evaluates to true, the routing_blockage is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for routing blockages level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-include_lib_cell`

Search for routing blockages in the *lib_cell*. By default, *lib_cell* routing_blockages are excluded from search.

This option must be used with *-hierarchical* option.

`-of_objects` *`of_objects`*

Creates a collection containing the routing blockages of the specified edit groups or cells. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together.

`patterns`

Matches the routing blockage names in the current design against the specified patterns. You can specify the patterns by using the following formats:

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all routing_blockages at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Feedback

`-within` *region*

Creates a collection that contains all routing_blockages that are completely inside the specified region and doesn't include routing_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all routing_blockages that are completely inside the specified region and the routing_blockages which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Feedback

`-intersect` *region*

Creates a collection that contains all routing_blockages which are abut/touching from inside or outside to the specified region and the routing_blockages whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command returns a collection of routing blockages of the current design that meet the selection criteria. You can also use this command to query routing blockages by filtering their attributes.

Examples

The following example returns the routing blockages whose area is larger than 1000.

```
prompt> get_routing_blockages * -filter "area > 1000"
{"RB_4683"}
```

The following example returns all routing blockages.

```
prompt> get_routing_blockages "RB_*"
{"RB_4683 RB_5389"}
```

The following example shows how to use *get_attribute* to query the value of the routing blockage attributes.

```
prompt> get_attribute [get_routing_blockages  RB_4683] layer
via3Blockage

prompt> get_attribute [get_routing_blockages RB_4683] bbox
{0.000 0.000{ {100.000 100.000}
```

Feedback

```
prompt> get_attribute [get_routing_blockages RB_4683] area
10000.000000
```

To get a complete report of the attribute values of all routing blockages, use the *report_attributes* command, as shown in the following example.

```
prompt> report_attributes -application [get_routing_blockages RB_4683]
Design  Object    Type   Attribute Name   Value
------------------------------------------------------------------------
CORE    RB_4683   float     area          10000.000000
CORE    RB_4683   string    bbox          {0.000 0.000} {100.000 100.000}
CORE    RB_4683   string    full_name     CORE/RB_4683
CORE    RB_4683   string    layer         via3Blockage
CORE    RB_4683   string    name          RB_4683
CORE    RB_4683   string    object_class  route_guide
```

See Also

- collections

- report_attributes

---

get_routing_channels

Creates a collection by selecting routing channels from the block.

Syntax

```
collection get_routing_channels
[-design design]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
```

Data Types

```
design            collection
exact_count       integer
minimum_count     integer
patterns          string
```

Feedback

Arguments

`-design` *design*

Specifies the block in which to find the routing channels.

By default, the tool finds objects in the current block.

`-quiet`

Suppresses warning and error messages if no object match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and the command processing stops.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns do not match, a Tcl error is raised and the command processing stops.

patterns

Matches the routing channel names against the patterns in the current block. If pattern is not specified, the command uses * (asterisk) as the *pattern*.

Feedback

Description

This command creates a collection of routing channels based on specified criteria and returns a collection if one or more routing channels which meet the selection criteria. If no routing channel matches the selection criteria, it returns an empty collection.

You can use the *get_routing_channels* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* man page for information about working with collections.

Examples

The following example gets all routing channels matching pattern routing_ch*.

```
prompt> get_routing_channels routing_ch*
{routing_ch_1 routing_ch_2}
```

The following example gets routing channels with name routing_channel_2.

```
prompt> get_routing_channels -filter "name==routing_channel_2"
{routing_channel_2}
```

---

get_routing_corridor_shapes

Creates a collection of routing corridor shapes from the current design.

Syntax

```
collection get_routing_corridor_shapes
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
```

Feedback

```
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design          collection
expression      string
exact_count     int
minimum_count   int
patterns        list
objects         list
region          list
point           list
```

Arguments

`-design` *design*

Specifies the top design in which to find objects. If this option is not specified, objects are found in the current design.

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing corridor shape attributes. You can determine the routing corridor shape attributes by using the *list_attributes* command. If the expression evaluates to *true*, the routing corridor shape is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

Checks whether each pattern in *patterns* matches at least one object. If one or more patterns does not match, the command raises a Tcl error and command processing will stop.

`-hierarchical`

Searches for routing corridor shapes level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-of_objects` *objects*

Creates a collection containing the routing corridor shapes of the specified routing corridors. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the routing corridor shape names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

IP "-at *point*" Creates a collection that contains all routing_corridor_shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all routing_corridor_shapes that are completely inside the specified region and doesn't include routing_corridor_shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all routing_corridor_shapes that are completely inside the specified region and the routing_corridor_shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all routing_corridor_shapes which are abut/touching from inside or outside to the specified region and the routing_corridor_shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of routing corridor shapes in the current design that match the specified criteria.

The command returns a collection if any routing corridor shapes match the specified criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as *query_objects*. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the *query_objects* command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples return the routing corridor shapes that match the specified patterns.

```
prompt> get_routing_corridor_shapes CORRIDOR_SHAPE_528896
{ CORRIDOR_SHAPE_528896 }

prompt> get_routing_corridors "CORRIDOR_SHAPE_*"
{ CORRIDOR_SHAPE_6 CORRIDOR_SHAPE_7 CORRIDOR_SHAPE_8
  CORRIDOR_SHAPE_9 }
```

The following example returns the routing corridor shapes that are associated with the corridor_a routing corridor.

```
prompt> get_routing_corridor_shapes \\
   -of_objects [get_routing_corridor corridor_a]
{ CORRIDOR_SHAPE_528896 CORRIDOR_SHAPE_528897 CORRIDOR_SHAPE_528898
  CORRIDOR_SHAPE_528899 CORRIDOR_SHAPE_528900 CORRIDOR_SHAPE_528901
  CORRIDOR_SHAPE_528902 CORRIDOR_SHAPE_528903 CORRIDOR_SHAPE_528904
  CORRIDOR_SHAPE_528905 }
```

Feedback

get_routing_corridors

Creates a collection of routing corridors from the current design.

Syntax

```
collection get_routing_corridors
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design          collection
expression      string
exact_count     int
minimum_count   int
patterns        list
objects         list
region          list
point           list
```

Arguments

`-design design`

Specifies the top design in which to find objects. If this option is not specified, objects are found in the current design.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing corridor attributes. You can determine the routing corridor attributes by using the *list_attributes* command. If the expression evaluates to *true*, the routing corridor is included in the collection. By default, this option is off.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Treats the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

[-hierarchical]
[patterns
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design         string
expression     string
exact_count    integer
minimum_count  integer
patterns       list
point          list
region         list
```

Feedback

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the routing guide attributes. You can determine the routing guide attributes by using the *list_attributes* command. If the expression evaluates to *true*, the routing guide is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. The option can be used when searching for objects that contain * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

Feedback

`-hierarchical`

Searches for routing guides level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*.

`patterns`

Matches routing guide names against patterns. Patterns can include the wildcard characters "*" and "?".

The *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all routing_guides at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*,*-within*,*-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *`region`*

Creates a collection that contains all routing_guides that are completely inside the specified region and doesn't include routing_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,*-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all routing_guides that are completely inside the specified region and the routing_guides which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,*-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all routing_guides which are abut/touching from inside or outside to the specified region and the routing_guides whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*,*-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of routing guides that meet the selection criteria. It returns a collection of routing guides if one or more routing guides meet the selection criteria. If no routing guides match the selection criteria, it returns an empty string.

You can use the *get_routing_guides* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the *collections* man page for information about working with collections.

Examples

The following example returns all routing guides:

```
prompt> get_routing_guides *
{RG_0 RG_1 RG_2}
```

The following example uses the *-hierarchical* option to return routing guides within child physical blocks.

```
prompt> get_routing_guides -hierarchical
{RG_0 RG_1 RG_2 mid/RG_0 mid/RG_1 mid/bot/RG_0}
```

The following example returns routing guides with an area greater than 1000.

```
prompt>get_routing_guides * -filter "area > 1000"
{RG_2}
```

---

get_routing_rules

Returns a collection of routing rules from the current design.

Syntax

```
collection get_routing_rules
[-design design]
[-filter expression]
[-quiet]
[-regexp]
```

Feedback

```
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects of_objects]
```

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list
patterns	string

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any routing rule that match the patterns option, the expression is evaluated based on the routing rule's attributes. If the expression evaluates to *true*, the routing rule is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection containing the routing rules of the specified nets. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches routing rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Description

The *get_routing_rules* command creates a collection of routing rules from the current design that match certain criteria. The command returns a collection of routing rules if any routing rule matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the *get_routing_rules* command at the command prompt, or you can nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_routing_rules* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the routing rules in the current design.

Feedback

```
prompt> get_routing_rules
{ndr1 test3}
```

The following example returns a collection of all the routing rules corresponding to a net.

```
prompt> get_routing_rules -of_objects Reset
{ndr3}
```

---

get_rp_blockages

Creates a collection by selecting relative placement blockages from the current design.

Syntax

```
collection get_rp_blockages
[patterns | -of_objects of_objects]
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
```

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list or collection
patterns	list

Feedback

Arguments

patterns

Matches the relative placement blockage names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

`-of_objects` *of_objects*

Creates a collection containing the relative placement blockages of the specified relative placement groups. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the relative placement blockage attributes. You can determine the relative placement blockage attributes by using the *list_attributes* command. If the expression evaluates to *true*, the relative placement blockage is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for relative placement blockages level-by-level relative to the current design. This option is useful only with *patterns* and not with *-of_objects*.

Description

This command creates a collection of relative placement blockages by selecting relative placement blockages that meet the selection criteria. It returns a collection handle if one or more relative placement blockages meet the selection criteria. If no relative placement blockages match the selection criteria, it returns an empty string.

You can use the *get_rp_blockages* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of relative placement blockages by name pattern matching.

```
prompt> get_rp_blockages rp_blockage*
{rp_blockage1 rp_blockage2 rp_blockage3}
```

The following example creates a collection of relative placement blockages with attribute filtering.

```
prompt> get_rp_blockages -filter {height == 2}
{rp_blockage1}
```

Feedback

The following example creates a collection of all relative placement blockages.

```
prompt> get_rp_blockages *
{rp_blockage1 rp_blockage2 rp_blockage3 rp_blkg4}
```

The following example creates a collection of parent relative placement blockages of relative placement group rp_group1.

```
prompt> get_rp_blockages -of_objects rp_group1}
{rp_blockage1}
```

---

get_rp_group_objects

Creates a collection by selecting cells or relative placement groups or blockages of given relative placement groups.

Syntax

```
collection get_rp_group_objects
rp_group_list
[-cell] | [-rp_group] | [-blockage]
[-hierarchical]
[-row row_number]
[-column column_number]
```

Data Types

```
rp_group_list       list or collection
row_number          integer
column_number       integer
```

Feedback

Arguments

rp_group_list

Specifies the list of names or collection of a relative placement groups, from which objects needs to be collected.

-cell

Specifies that cells of given relative placement groups must be collected.

-rp_group

Specifies that relative placement groups of given relative placement groups must be collected.

-blockage

Specifies that relative placement blockages of given relative placement groups must be collected.

-hierarchical

Specifies that objects from all sub-groups of relative placement groups in *rp_group_list* are to be collected. By default, objects in sub-groups are not collected.

-row

Specifies the row from which objects must be collected. By default, objects are collected from all rows of the relative placement group.

-column

Specifies the column from which objects must be collected. By default, objects are collected from all columns of the relative placement group.

Description

The *get_rp_group_objects* command returns a collection of cells, relative placement groups and/or blockages. By default, all objects of relative placement group are collected. If user provides *-cell* or *-rp_group* or *-blockage* then cells or relative placement groups or relative placement blockages will be collected respectively.

Examples

The following example uses *get_rp_group_objects* to create collection cells.

```
prompt> get_rp_group_objects grp_ripple -cell
{U0 U1 U2 U3}
```

The following example uses *get_rp_group_objects* to create collection relative placement groups.

Feedback

```
prompt> get_rp_group_objects grp_ripple -rp_group
{grp_ripple_hier1 grp_ripple_hier2}
```

The following example uses *get_rp_group_objects* to create collection relative placement blockages.

```
prompt> get_rp_group_objects grp_ripple -blockage
{grp_ripple_blkg}
```

The following example uses *get_rp_group_objects* to get object at given row and column location.

```
prompt> get_rp_group_objects grp_ripple -row 1 -column 1
{grp_ripple_blkg}
```

The following example uses *get_rp_group_objects* to get objects of a row.

```
prompt> get_rp_group_objects grp_ripple -row 1
{grp_ripple_blkg grp_ripple_hier2 U2 U3}
```

The following example uses *get_rp_group_objects* to get objects of a column.

```
prompt> get_rp_group_objects grp_ripple -column 1
{grp_ripple_blkg grp_ripple_hier1 U0 U1}
```

The following example uses *get_rp_group_objects* to get all objects of relative placement group.

```
prompt> get_rp_group_objects grp_ripple
{grp_ripple_blkg U0 U1 U2 U3 grp_ripple_hier1 grp_ripple_hier2}
```

The following example uses *get_rp_group_objects* to get all objects of relative placement group and its hierarchical relative placement groups.

```
prompt> get_rp_group_objects grp_ripple -hierarchical
{grp_ripple_blkg U0 U1 U2 U3 grp_ripple_hier1 grp_ripple_hier2 U5 U6 U7}
```

---

get_rp_groups

Creates a collection by selecting relative placement groups from the current design.

Feedback

Syntax

```
collection get_rp_groups
[patterns | -of_objects of_objects]
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-top]
[-hierarchical]
```

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list or collection
patterns	list

Arguments

patterns

Matches the relative placement group names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

-of_objects *of_objects*

Creates a collection containing the parent relative placement group of the specified cells, relative placement groups or relative placement blockages. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

-design *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *`expression`*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the relative placement group attributes. You can determine the relative placement group attributes by using the *list_attributes* command. If the expression evaluates to *true*, the relative placement group is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-top`

If specified with *patterns* then it specifies that only top level relative placement groups must be collected. The option when specified with *of_objects* collects top most relative placement group in parent hierarchy instead of parent relative placement group.

Feedback

`-hierarchical`

Searches for relative placement groups level-by-level relative to the current design. This option is useful only with *patterns* and not with *-of_objects*.

Description

This command creates a collection of relative placement groups by selecting relative placement groups that meet the selection criteria. It returns a collection handle if one or more relative placement groups meet the selection criteria. If no relative placement groups match the selection criteria, it returns an empty string.

You can use the *get_rp_groups* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of relative placement groups by name pattern matching.

```
prompt> get_rp_groups rp_group*
{rp_group1 rp_group2 rp_group3}
```

The following example creates a collection of relative placement groups with attribute filtering.

```
prompt> get_rp_groups -filter {tiling_type == bit_slice}
{rp_group1}
```

The following example creates a collection of all relative placement groups.

```
prompt> get_rp_groups *
{rp_group1 rp_group2 rp_group3 rp_group4}
```

The following example creates a collection of parent relative placement group of cell inv.

```
prompt> get_rp_groups -of_objects inv
{rp_group1}
```

---

get_rulers

Creates a collection by selecting rulers from the current block.

Syntax

collection *get_rulers*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the ruler attributes. You can determine the ruler attributes by using the *list_attributes* command. If the expression evaluates to *true*, the ruler is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design design_name`

Specifies the design module in which to search for rulers.

Feedback

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of rulers to find. If the command finds a different number of rulers, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of rulers to find. If the command finds fewer rulers, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one ruler. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for rulers level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the ruler names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the rulers that are associated with the specified objects.

If the objects are annotation points, the command returns the rulers which own the annotation points.

Feedback

Any object type that may be an anchor object of an annotation point may also be specified, such as cells, vias, and routing blockages for example, in which case the command returns the rulers which own the annotation points anchored to these objects.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Description

This command creates a collection of rulers that meet the selection criteria. It returns a collection handle if one or more rulers meet the selection criteria. If no ruler match the selection criteria, it returns an empty string.

You can use the *get_rulers* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of rulers by matching the name against the pattern:

```
prompt> get_rulers ruler*
{ruler0 ruler1 ruler2}
```

See Also

- create_ruler
- remove_rulers
- get_annotation_points

---

get_safety_core_groups

Returns a collection of safety core groups from the current design.

Syntax

status *get_safety_core_groups*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
```

Feedback

```
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[patterns]
```

Data Types

design	string
expression	string
exact_count	integer
minimum_count	integer
of_objects	collection
patterns	string

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any core group that match the patterns option, the expression is evaluated based on the safety core group attributes. If the expression evaluates to *true*, the safety core group is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-of_objects` *`of_objects`*

Creates a collection containing the safety core group of the specified safety cores. Each object in the list is a name, pattern, or collection.

`patterns`

Matches safety core group names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

Description

Finds and creates a collection of safety core group objects based on the options and filters specified. If no options are specified, it returns all the safety core groups of the current design.

Examples

The following example creates a collection of safety_core_group objects based on given pattern with case insensitive matching.

```
prompt> get_safety_core_groups -nocase group1*
```

See Also

- create_safety_core_group
- report_safety_core_groups

---

get_safety_core_rules

Returns a collection of safety core rules from the current design.

Syntax

status *get_safety_core_rules*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
```

Feedback

```
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[patterns]
```

Data Types

design	string
expression	string
exact_count	integer
minimum_count	integer
of_objects	collection
patterns	string

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any core rule that match the patterns option, the expression is evaluated based on the safety core rule attributes. If the expression evaluates to *true*, the safety core rule is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-of_objects` *of_objects*

Creates a collection containing the safety core rule of the specified safety cores. Each object in the list is a name, pattern, or collection.

patterns

Matches safety core rule names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

Description

Finds and creates a collection of safety core rule objects based on the options and filters specified. If no options are specified, it returns all the safety core rules of the current design.

Examples

The following example creates a collection of safety_core_rule objects based on given pattern with case insensitive matching.

```
prompt> get_safety_core_rules -nocase rule1*
```

See Also

- create_safety_core_rule
- report_safety_core_rules

---

get_safety_error_code_groups

Creates a collection of safety error code groups.

Syntax

status *get_safety_error_code_groups*

Feedback

```
[patterns]
[-of_objects pins_or_ports]
[-filter expression]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect count]
[-expect_at_least count]
[-expect_each_pattern_matches]
```

Data Types

patterns	string
pins_or_ports	collection
expression	string
count	integer

Arguments

patterns

Finds the safety error code groups with names matching these patterns.

-of_objects *pins or ports*

Gets the safety error code groups associated with these data or checkbits pins or ports.

-filter *expression*

Filters the collection with *expression*.

-quiet

Does not print any messages.

-regexp

Specifies that patterns are full regular expressions.

-exact

Specifies that wildcards are considered as plain characters.

-nocase

Performs case-insensitive matching.

-expect *count*

Expects exactly these many matching objects: count >= 0.

-expect_at_least *count*

Expects at least these many matching objects: count >= 1.

Feedback

`-expect_each_pattern_matches`

Specifies that each pattern must match at least one object.

Description

This command finds and creates a collection of safety_error_code_group objects based on the options and filters specified. If no options are specified, it returns all the safety error code groups of the current design.

Examples

The following example creates a collection of safety error code group objects based on given pattern with case insensitive matching.

```
prompt> get_safety_error_code_groups -nocase group1*
```

See Also

- create_safety_error_code_group
- report_safety_error_code_groups

---

get_safety_error_code_rules

Creates a collection of safety error code rules.

Syntax

status *get_safety_error_code_rules*

```
[patterns]
[-of_objects pins_or_ports]
[-filter expression]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect count]
[-expect_at_least count]
[-expect_each_pattern_matches]
```

Data Types

patterns	string
pins_or_ports	collection
expression	string
count	integer

Feedback

Arguments

patterns

Finds safety error code rules with names matching these patterns.

-of_objects *pins or ports*

Gets the safety error code rules associated with these data pins or ports using *set_safety_error_code_rule* command.

-filter *expression*

Filters collection with *expression*.

-quiet

Does not print any messages.

-regexp

Specifies that patterns are full regular expressions.

-exact

Specifies that wildcards are considered as plain characters.

-nocase

Performs case-insensitive matching.

-expect *count*

Expects exactly these many matching objects: count >= 0.

-expect_at_least *count*

Expects at least these many matching objects: count >= 1.

-expect_each_pattern_matches

Specifies that each pattern must match at least one object.

Description

This command finds and creates a collection of safety error code rule objects based on the options and filters specified. If no options are specified, it returns all the safety error code rules of the current design.

Examples

The following example creates a collection of safety_error_code_rule objects based on given pattern with case insensitive matching.

```
prompt> get_safety_error_code_rules -nocase rule1*
```

Feedback

See Also

- create_safety_error_code_rule
- report_safety_error_code_rules
- set_safety_error_code_rule

---

get_safety_register_groups

Creates a collection of safety register groups.

Syntax

status *get_safety_register_groups*

```
[patterns]
[-of_objects cells]
[-filter expr]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect count]
[-expect_at_least count]
[-expect_each_pattern_matches]
```

Data Types

patterns	string
cells	collection
expr	string
count	integer

Arguments

patterns

Finds safety register groups with names matching these patterns.

-of_objects *cells*

Gets safety register groups associated with these registers or pins.

-filter *expression*

Filters collection with *expression*.

-quiet

Does not print any messages.

Feedback

`-regexp`

Specifies that patterns are full regular expressions.

`-exact`

Specifies that wildcards are considered as plain characters.

`-nocase`

Performs case-insensitive matching.

`-expect` *count*

Expects exactly these many matching objects: count >= 0.

`-expect_at_least` *count*

Expects at least these many matching objects: count >= 1.

`-expect_each_pattern_matches`

Specifies that each pattern must match at least one object.

Description

This command finds and creates a collection of safety_register_group objects based on the options and filters specified. If no options are specified, it returns all the safety register groups of the current design.

Examples

The following example creates a collection of safety register group objects based on given pattern with case insensitive matching.

```
prompt> get_safety_register_groups -nocase group1*
```

See Also

- create_safety_register_group
- report_safety_register_groups
- write_safety_register_script

---

get_safety_register_rules

Creates a collection of safety register rules.

Syntax

status *get_safety_register_rules*

Feedback

```
[patterns]
[-of_objects registers]
[-filter expr]
[-quiet]
[-regexp]
[-exact]
[-nocase]
[-expect count]
[-expect_at_least count]
[-expect_each_pattern_matches]
```

Data Types

patterns	string
registers	collection
expr	string
count	integer

Arguments

patterns

Finds safety register rules with names matching these patterns.

-of_objects *registers*

Gets safety register rules associated with these registers or pins.

-filter *expression*

Filters collection with *expression*.

-quiet

Does not print any messages.

-regexp

Specifies that patterns are full regular expressions.

-exact

Specifies that wildcards are considered as plain characters.

-nocase

Performs case-insensitive matching.

-expect *count*

Expects exactly these many matching objects: count >= 0.

-expect_at_least *count*

Expects at least these many matching objects: count >= 1.

Feedback

`-expect_each_pattern_matches`

Specifies that each pattern must match at least one object.

Description

This command finds and creates a collection of safety register rule objects based on the options and filters specified. If no options are specified, it returns all the safety register rules of the current design.

Examples

The following example creates a collection of safety_register_rule objects based on given pattern with case insensitive matching.

```
prompt> get_safety_register_rules -nocase rule1*
```

See Also

- create_safety_register_rule
- report_safety_register_rules
- write_safety_register_script

---

get_scan_cell_names

Returns a list containing the names of scan cells for the specified option filters.

Syntax

list *get_scan_cell_names*

```
[-chain chain_name_list]
[-test_mode mode_name_list | all]
[-use_ctl_information true | false]
```

Data Types

```
chain_name_list          list
mode_name_list           list
```

Arguments

`-chain chain_name_list`

When specified, retrieves and returns a list of scan cell names contained in the specified scan chains. By default, the scan cells for all chains are returned.

Feedback

`-test_mode` *`mode_name_list`* `|` `all`

Reports only on the specified test mode(s), or on all test modes if *all* is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

`-use_ctl_information true | false`

Enables reporting of virtual cells defined inside CTL models. By default, this option is false and does not report the names of cells that do not exist in the netlist.

Description

This command returns a Tcl list of scan cell names (as strings), according to the specified options. The information can include scan paths defined by the *set_scan_path* command, as well as scan paths created by the tool.

By default, the command returns the scan cell names for all chains.

---

get_scan_cells_of_chain

Returns a collection containing all scan cells of the specified scan chain.

Syntax

collection *get_scan_cells_of_chain*

`-chain` *`chain_name`*

Data Types

`chain_name` `string`

Feedback

Arguments

`-chain` *chain_name*

Specifies the name of the scan chain.

Description

This command returns a Tcl collection containing all scan cells for the specified scan chain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

This example gets all scan cells of the *chain1* scan chain:

```
prompt> get_scan_cells_of_chain -chain "chain1"
```

---

get_scan_chain_collection

Returns a Tcl list containing the names of the SCANDEF stub chains of the design.

Syntax

```
list get_scan_chain_collection
```

Arguments

This command does not receive any arguments.

Description

This command returns a Tcl list containing the names of the SCANDEF stub chains of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

This example gets the scan chain names of the design:

```
prompt> get_scan_chain_collection
{ chain1 2 3 4 }
prompt>
```

See Also

- get_scan_chain_count

Feedback

get_scan_chain_count

Returns the number of SCANDEF stub chains in the current design.

Syntax

int *get_scan_chain_count*

Description

This command returns the number of SCANDEF stub chains in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

This example returns the number of scan chains in the design:

```
prompt> get_scan_chain_count
203
```

See Also

- get_cells_of_scan_chain

get_scan_chain_names

Returns a list containing the names of scan chains for the specified option.

Syntax

list *get_scan_chain_names*

```
[-test_mode mode_name_list | all]
```

Data Types

```
mode_name_list          list
```

Arguments

```
-test_mode mode_name_list | all
```

Reports only on the specified test mode(s), or on all test modes if *all* is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

Feedback

Description

This command returns a Tcl list of scan chain names according to the specified option. The information can include scan paths defined by the *set_scan_path* command, as well as scan paths created by the tool.

---

get_scan_chain_of_cell

Returns a Tcl list containing the name of the SCANDEF stub chain to which the given cell belongs.

Syntax

string *get_scan_chain_of_cell*

```
-cell cell_name
```

Data Types

```
cell_name       string
```

Arguments

```
-cell cell_name
```

Specifies the name of the cell whose scan chain is looked for.

Description

This command returns a Tcl list containing the name of the SCANDEF stub chain corresponding to the given cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

This example gets the chain name *chain1* corresponding to the cell *blockA/a_cell*.

```
prompt> get_scan_chain_of_cell -cell blockA/a_cell
{ chain1 }
prompt>
```

See Also

- get_scan_chain_count

---

get_scan_segments

Returns a list containing the names of CTL scan chains for the specified instances and/or modules.

Syntax

list *get_scan_segments*

```
-instance_name cell_name
-module_name design_name
```

Arguments

`-instance_name`

This option specifies the cell names for which CTL scan chains are fetched.

`-module_name`

This option specifies the design names for which CTL scan chains are fetched.

Description

This command returns a list of CTL scan chains, according to the options specified. Either one of the options, instance_name or module_name, has to be specified. If both options are specified, then the scan chains common to both will be returned. Multilple values, including collections, can be specified for both options. The -instance option also supports wildcards.

Examples

The following command returns a list of CTL scan chains from specified instances and/or modules

```
prompt> get_scan_segments -instance test*
test_mem/1 test_mem/2 test_mem/3 test_mem/4 test_mem/test_chain
 test_mem/6 test_mem2/1 test_mem2/2 test_mem2/3 test_mem2/4
 test_mem2/test_chain test_mem2/6
```

Feedback

```
prompt> get_scan_segments -module_name
 sasuls0g4u2p4096x18m8b2w0c1p0d0s2rm4rw00e10h0ms0 -instance test_mem*
test_mem/1 test_mem/2 test_mem/3 test_mem/4 test_mem/test_chain
 test_mem/6 test_mem2/1 test_mem2/2 test_mem2/3 test_mem2/4
 test_mem2/test_chain test_mem2/6

prompt> get_scan_segments -module_name
 sasuls0g4u2p4096x18m8b2w0c1p0d0s2rm4rw00e10h0ms0 -instance test_mem2
test_mem2/1 test_mem2/2 test_mem2/3 test_mem2/4 test_mem2/test_chain
 test_mem2/6

prompt> get_scan_segments -module_name
 sasuls0g4u2p4096x18m8b2w0c1p0d0s2rm4rw00e10h0ms0
1 2 3 4 test_chain 6

prompt> get_scan_segments -instance_name [get_cell -hier test*]
test_mem/1 test_mem/2 test_mem/3 test_mem/4 test_mem/test_chain
 test_mem/6 test_mem2/1 test_mem2/2 test_mem2/3 test_mem2/4
 test_mem2/test_chain test_mem2/6

prompt> get_scan_segments -module_name [get_modules
 sasuls0g4u2p4096x18m8b2*]
1 2 3 4 test_chain 6
```

See Also

- get_scan_chain_names

---

get_scenarios

Creates a collection of scenarios in the current design.

Syntax

collection *get_scenarios*

```
[patterns | -of_objects of_objects]
[-modes mode_list]
[-corners corner_list]
[-design design]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-quiet]
[-regexp]
[-nocase]
[-filter expression]
string expression
```

Feedback

```
list patterns
list of_objects
list mode_list
list corner_list
```

Arguments

patterns

Matches scenario names against patterns. Patterns can include the wildcard characters "*" and "?".

The *patterns* argument; *-of_objects* option; and *-modes* and *-corners* options are mutually exclusive; you can specify only one. If you do not specify any of these, the generated collection contains all scenarios.

`-of_objects` *of_objects*

Creates a collection of scenarios that are associated with the specified objects. Each object is a named mode or corner, or mode or corner collection.

The *patterns* argument; *-of_objects* option; and *-modes* and *-corners* options are mutually exclusive; you can specify only one. If you do not specify any of these, the generated collection contains all scenarios.

`-modes` *mode_list*

Creates a collection of scenarios that are associated with the specified modes.

If you use both the *-modes* and *-corners* options, the scenarios are associated with one of the specified modes and one of the specified corners.

You cannot use the *-modes* or *-corners* options with the *-of_objects* option or *patterns* argument. If you do not specify any of these, the generated collection contains all scenarios.

`-corners` *corner_list*

Creates a collection of scenarios that are associated with the specified corners.

If you use both the *-modes* and *-corners* options, the scenarios are associated with one of the specified modes and one of the specified corners.

You cannot use the *-modes* or *-corners* options with the *-of_objects* option or *patterns* argument. If you do not specify any of these, the generated collection contains all scenarios.

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-filter` *`expression`*

Filters the collection with *expression*. For any scenarios that match *patterns*, the expression is evaluated based on the scenario's attributes. If the expression evaluates to true, the scenario is included in the result.

Description

The *get_scenarios* command creates a collection of scenarios in the current design that match the *patterns* argument, the *-of_objects* option, or the *-modes* and *-corners* options, and that pass the filter (if specified). If no objects match the criteria, the empty string is returned.

With the correct combination of options, this command can return all the scenarios of a given mode or corner, or the single scenario (if any) of a given mode and corner.

Feedback

Examples

The following example returns all scenarions.

```
prompt> get_scenarios
{func::corner_S1_max func::corner_S1_min func::corner_S5_max
func::corner_S5_min func::corner_S7_max func::corner_S7_min}
```

The following example returns all scenarios whose name matches the pattern *min.

```
prompt> get_scenarios *min
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}
```

The following example returns all active setup scenarios.

```
prompt> get_scenarios -filter setup&&active
{func::corner_S1_max func::corner_S5_max func::corner_S7_max}
```

The following examples return all scenarios that use a corner that matches the pattern *min.

```
prompt> get_scenarios -corners *min
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}

prompt> get_scenarios -of_objects [get_corners *min]
{func::corner_S1_min func::corner_S5_min func::corner_S7_min}
```

The following example returns the scenarios that use a corner named *min or a mode named func (or both).

```
prompt> get_scenarios -of_objects [add_to_collection \\
   [get_corners *min] [get_modes func]]
{func::corner_S1_min func::corner_S5_min func::corner_S7_min
func::corner_S1_max func::corner_S5_max func::corner_S7_max}
```

The following example returns the scenarios that use the func mode and the corner_S7_max corner.

```
prompt> get_scenarios -corners corner_S7_max -modes func
{func::corner_S7_max}
```

---

get_selection

Returns a collection containing the current selection in the GUI.

Syntax

```
collection get_selection
[-slct_targets target_selection_bus
  [-slct_targets_operation operation]]
-create_slct_buses
[-name selection_bus]
[-type object_type]
[-design design]
[-more_than more]
[-fewer_than fewer]
[-count]
[-num num]
[-type_list]
```

Data Types

target_selection_bus	string
operation	string
selection_bus	string
object_type	string
design	string
more	integer
fewer	integer
num	integer

Arguments

`-slct_targets` *target_selection_bus*

Specifies the name of a selection bus in which to store the result. When you use this option, the *target_selection_bus* value is also returned as result of the command. By default, the result is returned in a collection.

`-slct_targets_operation` *operation*

Specifies which operation should be used when storing the result in the selection bus specified by the *target_selection_bus* argument. The valid values for the *operation* argument are *clear*, *add*, and *remove*. You can use the *-slct_targets_operation* option only if you also use the *-slct_targets* option.

Feedback

`-create_slct_buses`

Specifies to create a new selection bus in which to store the result. Using this option is equivalent to using the *create_selection_bus* command to create a selection bus and then providing the created selection bus to the *-slct_targets* option.

`-name` *`selection_bus`*

Specifies the selection bus from which the selection is taken.

`-type` *`object_type`*

Specifies the type of selected object with which to filter the selection. The valid values for *object_type* and their descriptions are as follows:

```
design -design object
port -port object
net -net object
cell -cell object
pin -pin object
path -timing path object
```

`-design` *`design`*

Returns only objects in the filter specified by the value of *design*.

`-more_than` *`more`*

Returns true if the selection bus contains more than the number of objects specified by *more*.

`-fewer_than` *`fewer`*

Returns true if the selection bus contains more than the number of objects specified by *fewer*.

`-count`

Returns the number of elements contained in the selection bus.

`-num` *`num`*

Returns only the number of objects specified by *num* or fewer.

`-type_list`

Returns a Tcl list of the types of elements contained in the selection bus.

Description

This command returns the current selection in the tool as a collection. It returns a collection handle (identifier) if any objects are selected. If no objects are selected, the command returns an empty string. If you do not use the *-type* option, the command

Feedback

returnS a heterogeneous collection of all objects currently selected. If you use *-type*, the collection is filtered to a homogeneous one containing only objects of the type you specify.

You can use the *get_selection* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*), or assign the *get_selection* result to a variable.

When issued from the command prompt, *get_selection* behaves as if you had called *query_objects* to display the objects in the collection. By default, the command displays a maximum of 100 objects. You can change this maximum by using the *collection_result_display_limit* variable.

The "implicit query" property of *get_selection* provides a fast, simple way to display cells in a collection. However, if you want the flexibility provided by the options of the *query_objects* command (for example, if you want to display the object class), use *get_selection* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns the collection of the selected cell objects.

```
prompt> get_selection -type cell
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

The following example assigns the collection to a variable named *collect_a* that is passed to the *query_objects* command.

```
prompt> set collect_a [get_selection -type cell]
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
prompt> query_objects $collect_a
{"I_PRGRM_CNT_TOP", "I_DATA_PATH", "I_REG_FILE", "I_STACK_TOP"}
```

See Also

- change_selection
- collections
- filter_collection
- query_objects

---

get_shape_patterns

Creates a collection by selecting shape_patterns from the block.

Feedback

Syntax

```
collection get_shape_patterns
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within { { {llx lly} {urx ury} } |
              { {x y} {x y} {x y} {x y} ... } } |
              geometric_objects
  | -touching { { {llx lly} {urx ury} } |
               { {x y} {x y} {x y} {x y} ... } } |
               geometric_objects
  | -intersect { { {llx lly} {urx ury} } |
                { {x y} {x y} {x y} {x y} ... } } |
                geometric_objects]
```

Data Types

design	collection
expression	string
exact_count	integer
minimum_count	integer
patterns	string
objects	list
point	list
llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection

Arguments

`-design` *design*

Specifies the block in which to find shape_patterns.

By default, the tool finds objects in the current block.

Feedback

`-filter` *`expression`*

Filters the collection with the value of *expression*, which must be a Boolean expression based on shape_pattern attributes. You can determine the shape_pattern attributes by using the *list_attributes -class shape_pattern* command. If the expression evaluates to *true*, the shape_pattern is included in the collection.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for shape_patterns level-by-level relative to the current instance. You can use this option with the *patterns*, *-within*, *-touching*, *-intersect*, and *-at* arguments, but not with the *-of_objects* option.

Feedback

`-of_objects` *`of_objects`*

Creates a collection that contains the shape_patterns connected to the specified net, layer, edit group, or group. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches the shape_pattern names against the patterns in the current block. You can specify the patterns by using the following formats:

- * (asterisk) specifies all shape_patterns
- *PATH_PATTERN_** specifies all shape_patterns with shape_pattern_type path_pattern
- *RECT_PATTERN_** specifies all shape_patterns with shape_pattern_type rect_pattern

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all shape_patterns whose region completely contains the input point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-within` *`region`*

Creates a collection that contains all shape_patterns completely contained inside the specified region. All objects which are abut/touching from inside and completely contained also get selected.

Feedback

When the *design.enable_icc_region_query* application option is set to *true*, only the objects which are completely contained but not abut/touching from inside get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-touching` *`region`*

Creates a collection that contains all shape_patterns completely contained by the specified region. All objects which are touching from inside and completely contained also get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-intersect` *region*

Creates a collection that contains all shape_patterns whose region intersects the specified region. A certain portion of the region should be completely inside and a certain portion outside of the input window to pass this test.

When the *design.enable_icc_region_query* application option is set to *true*, even the objects which are abut/touching from either inside or outside also get selected.

The region can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

Polygons can also be specified as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

Region specified can be a disjointed rectangle or polygon.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

Description

This command creates a collection of shape_patterns by selecting shape_patterns from the nets, layer, edit group, or group that meet the selection criteria. It returns a collection if one or more shape_patterns meet the selection criteria. If no shape_patterns match the selection criteria, it returns an empty string.

Feedback

You can use the *get_shape_patterns* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example gets all shape_patterns connected to the specified net.

```
prompt> get_shape_patterns * -of_objects [get_nets VDD]
{PATH_PATTERN_31_0 PATH_PATTERN_31_1}
```

The following example creates a collection of shape_patterns on the M2 layer.

```
prompt> get_shape_patterns -of_objects [get_layers M2]
{RECT_PATTERN_32_0 RECT_PATTERN_32_1 PATH_PATTERN_32_99 ...}
```

---

get_shapes

Creates a collection by selecting shapes from the block.

Syntax

```
collection get_shapes
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_fill]
[-include_lib_cell]
[-include_shield]
[-shield_only]
```

Feedback

```
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design            collection
expression        string
exact_count       integer
minimum_count     integer
patterns          string
objects           list
point             list
region            list
```

Arguments

`-design design`

Specifies the block in which to find shapes.

By default, the tool finds objects in the current block.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on shape attributes. You can determine the shape attributes by using the *list_attributes -class shape* command. If the expression evaluates to *true*, the shape is included in the collection.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. The *-exact* and *-regexp* options are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for shapes level-by-level relative to the current instance. You can use this option with the *patterns*, *-within*,\ fB-touching*, -intersect, and -at arguments, but not with the -of_objects option.*

`-include_fill`

Search for fill shapes. You must specify the *-hierarchical* option to search the *fill cell hierarchy* instance in the current block.

By default, fill shapes are excluded from search.

`-include_lib_cell`

Search for shapes in library cells. You must specify the *-hierarchical* option to search for shapes in the library cells.

By default, library cell shapes are excluded from search.

`-include_shield`

Includes shield shapes when the *-of_objects* option specifies nets. This option is valid only when the *-of_objects* option specifies nets.

This option is mutually exclusive with the *-shield_only* option.

`-shield_only`

Search only for shield shapes when the *-of_objects* option specifies nets. This option is valid only when the *-of_objects* option specifies nets.

This option is mutually exclusive with the *-include_shield* option.

`-of_objects` *`of_objects`*

Creates a collection that contains the shapes connected to the specified net, port, pin, terminal, library cell pin, layer, edit group, or fill cell. Each object in the list is a name, pattern, or collection.

Feedback

When you specify ports, the *get_shapes* command searches for shapes attached to the terminals associated with the specified ports.

When you specify pins, the *get_shapes* command searches for shapes attached to the terminals of the ports associated with the specified pins.

When you specify fill cells, the *get_shapes* command searches for shapes contained in the specified fill cells.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches the shape names against the patterns in the current block. You can specify the patterns by using the following formats:

- * (asterisk) specifies all shapes
- *PATH_** specifies all path shapes
- *RECT_** specifies all rectangle shapes

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at point`

Creates a collection that contains all shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-within region`

Creates a collection that contains all shapes that are completely inside the specified region and does not include shapes that abut the specified region or touch it from the inside. The region boundary can be a rectangle or polygon.

Feedback

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-touching` *region*

Creates a collection that contains all shapes that are completely inside the specified region and the shapes that abut the specified region or touch it from the inside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

`-intersect` *region*

Creates a collection that contains all shapes that abut the specified region or touch it from the inside or outside. The region boundary can be a rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}}, which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one. However, you can specify the *-within* and *-intersect* options together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, the query is limited to the current physical hierarchy. To query objects across physical hierarchies, use the *-hierarchical* option.

Description

This command creates a collection of shapes by selecting shapes from the nets, ports, pins, or layers that meet the selection criteria. It returns a collection if one or more shapes meet the selection criteria. If no shapes match the selection criteria, it returns an empty string.

You can use the *get_shapes* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* man page for information about working with collections.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example gets all shapes connected to the specified net.

```
prompt> get_shapes -of_objects [get_nets net1]
{PATH_31_0 PATH_31_1}
```

The following example creates a collection of shapes on the M2 layer.

```
prompt> get_shapes -of_objects [get_layers M2]
{RECT_32_0 RECT_32_1 PATH_32_99 ...}
```

The following example creates a collection of path shapes.

```
prompt> get_shapes -filter {number_of_points > 2}
{PATH_31_2375 PATH_31_2396 PATH_32_2294 PATH_32_2301}
```

---

get_shaping_blockages

Creates a collection of shaping blockages from the current design.

Syntax

```
collection get_shaping_blockages
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects objects]
```

Data Types

```
design              collection
expression          string
exact_count         int
minimum_count       int
patterns            string
objects          list
```

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-filter expression`

Filters the collection with *expression*. For any shaping blockages that match *patterns*, the expression is evaluated based on the shaping blockage's attributes. If the expression evaluates to true, the blockage is included in the result.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for shaping blockages level-by-level relative to the current instance. This option is useful only with *patterns* and not with *-of_objects*.

`-of_objects` *`of_objects`*

Creates a collection containing the shaping blockages of the specified cells or blocks. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Feedback

patterns

Matches the shaping blockage names in the current design against the specified patterns. You can specify the patterns by using the following formats:

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

Description

This command returns a collection of shaping blockages of the current design that meet the selection criteria. You can use this command to query the shaping blockages inside the database by area, by point, or by region. You can also use this command to query shaping blockages by filtering their attributes.

Examples

The following example returns the shaping blockages whose area is larger than 1000.

```
prompt> get_shaping_blockages * -filter "area > 1000"
{"SB_4683"}
```

The following example returns all shaping blockages that begin with "SB_".

```
prompt> get_shaping_blockages "SB_*"
{"SB_4683 SB_5389"}
```

The following three commands show how to use *get_attribute* to query the value of the shaping blockage attributes.

```
prompt> get_attribute [get_shaping_blockages SB_4683] layer
via3Blockage

prompt> get_attribute [get_shaping_blockages SB_4683] bbox
{0.000 0.000{ {100.000 100.000}

prompt> get_attribute [get_shaping_blockages SB_4683] area
10000.000000
```

To get a complete report of the attribute values of all shaping blockages, use the *report_attributes* command, as shown in the following example.

```
prompt> report_attributes -application [get_shaping_blockages SB_4683]
Design  Object    Type   Attribute Name   Value
-------------------------------------------------------------------
CORE    SB_4683   float     area          10000.000000
CORE    SB_4683   string    bbox          {0.000 0.000} {100.000 100.000}
CORE    SB_4683   string    full_name     CORE/SB_4683
CORE    SB_4683   string    name          SB_4683
CORE    SB_4683   string    object_class  route_guide
```

---

get_shaping_channels

Get a collection of channels in the current block.

Syntax

collection *get_shaping_channels*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[-types type list]
[patterns]
```

Data Types

```
design        design
expression    filter_expression
exact_count   int
minimum_count int
of_objects    collection
type list     list of shaping constraint typesi
```

Arguments

`[-design]`

The -design argument specifies the top design for finding objects.

`[-filter]`

The -filter argument filters the collection based on the criteria given in the filter expression.

Feedback

`[-quiet]`

The -quiet argument suppresses all messages.

`[-regexp]`

The -regexp argument causes the command to treat the patterns as full regular expressions.

`[-nocase]`

The -nocase argument performs case-insensitive matching.

`[-exact]`

The -exact argument treats wildcards as plain characters.

`[-expect exact_count]`

The -expect argument tells the command to expect exactly this many matching objects.

`[-expect_at_least minimum_count]`

The -expect argument tells the command to expect at least this many matching objects.

`[-expect_each_pattern_matches]`

The -expect_each_pattern_matches argument requires that each pattern match at least one object.

`[-of_objects of_objects]`

The -of_objects argument specifies a list of objects from which to gather the shaping channel objects. The objects may be of type shaping_constraint, in which case the command gathers the shaping channels associated with the given shaping_constraint objects. The objects may also be of types voltage_area, move_bound, cell, shaping group, or block, in which case the command gathers the shaping channels associated with any shaping constraints defined for the given objects.

`[-types type list]`

The -types argument specifies a list of channel types to filter the result. The valid types are object and neighbor.

`[patterns]`

The patterns argument gives the patterns to match channel names against.

Description

Gathers a returns a collection of channel objects in the current design that match the set of collection criteria.

Feedback

Examples

The following command gets all the channel objects.

```
prompt> get_shaping_channels
```

The following command gets all the channel objects of type object.

```
prompt> get_shaping_channels -type object
```

See Also

- create_shaping_channel
- remove_shaping_channels

---

get_shaping_constraints

Creates a collection of shaping constraint objects

Syntax

collection *get_shaping_constraints*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[-types type_list]
[-hierarchical]
[patterns]
```

Data Types

```
design        collection
expression    string
exact_count   integer
minimum_count integer
of_objects    collection
type_list     list
```

Arguments

`-design design`

Specifies the top design for finding the objects.

Feedback

`-filter` *expression*

Filters the collection based on the criteria given in the filter expression.

`-quiet`

Suppresses all messages.

`-regexp`

Specifies that the command treats the patterns as full regular expressions.

`-nocase`

Performs case-insensitive matching.

`-exact`

Specifies that the command treats the wildcards as plain characters.

`-expect` *exact_count*

Specifies an expected number of objects to find.

`-expect_at_least minimum_count`

Specifies a minimum number of objects to find.

`-expect_each_pattern_matches`

When specified, this option requires that each pattern must match at least one object.

`-of_objects` *of_objects*

Specifies a list of objects from which to gather the shaping constraint objects.

`-types` *type_list*

Specifies a list of shaping constraint types to filter the result. The valid types are *alignment_point*, *allowable_orientation*, *array_layout*, *aspect_ratio*, *boundary_area*, *boundary_channels*, *boundary_status*, *child_default_channels*, *child_default_utilization*, *external_channels*, *is_rigid_boundary*, *parent_object*, *reference_region*, *target_location*, *utilization*.

`-hierarchical`

Searches to return results from the current context as well as all hierarchical levels under the current context.

`patterns`

Matches the shaping constraint names against pattern.

Feedback

Description

Gathers and returns a collection of the shaping constraint objects in the current design that match the set of selection criteria.

Examples

The following command gets all the shaping_constraint objects.

```
prompt> /fBget_shaping_constraints/fP
```

The following command gets all the shaping_constraint objects of types target_location and alignment_point.

```
prompt> /fBget_shaping_constraints -types "target_location
 alignment_point"/fP
```

See Also

- create_shaping_constraint
- remove_shaping_constraints

---

get_site_arrays

Returns a collection of site arrays from the current design.

Syntax

```
collection get_site_arrays
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design            collection
expression        string
exact_count       int
```

Feedback

```
minimum_count      int
patterns           string
objects            list
region             list
point              list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any site array that matches the patterns option, the expression is evaluated based on the site array's attributes. If the expression evaluates to *true*, the site array is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

Feedback

`-hierarchical`

Searches for site arrays level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-of_objects` *objects*

Creates a collection containing the site arrays of the specified voltage areas and site rows. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches site array names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *point*

Creates a collection that contains all site_arrays at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all site_arrays that are completely inside the specified region and doesn't include site_arrays which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all site_arrays that are completely inside the specified region and the site_arrays which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all site_arrays which are abut/touching from inside or outside to the specified region and the site_arrays whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

The *get_site_arrays* command creates a collection of site arrays from the current design that match certain criteria. The command returns a collection of site arrays if any site array matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the *get_site_arrays* command at the command prompt, or you can nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_site_arrays* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the site arrays in the current design.

```
prompt> get_site_arrays
{array_1 array_2 array_3}
```

The following example returns a collection of all the site arrays associated with a specified voltage area.

```
prompt> get_site_arrays -of_objects VA1
{SA1_1 SA1_2}
```

See Also

- create_site_array
- collections
- query_objects
- shell.common.collection_result_display_limit

Feedback

get_site_defs

Returns a collection of site defs from the tech of current or specified library.

Syntax

```
collection get_site_defs
[-library library]
[-tech tech_object]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects of_objects]
```

Data Types

```
library           string or collection
tech_object       collection
expression        string
exact_count       int
minimum_count     int
of_objects        list
patterns          string
```

Arguments

`-library library`

Site definition will be searched in the technology of this library. Default is current library's tech. This is mutually exclusive with -tech option.

`-tech tech_object`

Site definition will be searched in this technology. Default is current library's tech. This is mutually exclusive with -library option.

`-filter expression`

Filters the collection with *expression*. For any site def that match the patterns option, the expression is evaluated based on the site def's attributes. If the expression evaluates to *true*, the site def is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

Feedback

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection containing the site defs of the specified site rows, site arrays and lib cells. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches site def names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Description

The *get_site_defs* command creates a collection of site defs from the tech of the current or specified library that match certain criteria. The command returns a collection of site

Feedback

defs if any site def matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the *get_site_defs* command at the command prompt, or you can nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_site_defs* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the site defs in the tech of current library.

```
prompt> get_site_defs
{SD_1 SD_2 SD_3}
```

The following example returns a collection of all the site defs belonging to a site array.

```
prompt> get_site_defs -of_objects SA1
{SD1_1}
```

See Also

- collections
- query_objects
- shell.common.collection_result_display_limit

---

get_site_rows

Returns a collection of site rows from the current design.

Syntax

```
collection get_site_rows
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-first_row]
[patterns
  | -of_objects objects
```

Feedback

```
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design              collection
expression          string
exact_count         int
minimum_count       int
patterns            string
objects             list
region              list
point               list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any site row that match the patterns option, the expression is evaluated based on the site row's attributes. If the expression evaluates to *true*, the site row is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for site rows level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-first_row`

This will give first site-row with respect to core area. First site-row will be left-most for vertical site-rows, or the bottom-most for horizontal site-rows with respect to core area bounding box.

`-of_objects` *`of_objects`*

Creates a collection containing the site rows of the specified edit groups and site arrays. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches site row names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all site_rows at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all site_rows that are completely inside the specified region and doesn't include site_rows which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all site_rows that are completely inside the specified region and the site_rows which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all site_rows which are abut/touching from inside or outside to the specified region and the site_rows whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

The *get_site_rows* command creates a collection of site rows from the current design that match certain criteria. The command returns a collection of site rows if any site row matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the *get_site_rows* command at the command prompt, or you can nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_site_rows* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the site rows in the current design.

Feedback

```
prompt> get_site_rows
{ROW_1 ROW_2 ROW_3}
```

The following example returns a collection of all the site rows that belong to site array SA1.

```
prompt> get_site_rows -of_objects SA1
{SA1_1 SA1_2}
```

See Also

- collections
- query_objects
- shell.common.collection_result_display_limit

---

get_snap_setting

Returns the current snap setting for the specified option.

Syntax

status *get_snap_setting*

```
-enabled |
-class obj_class |
-cursor_edge |
-cursor_snap_type |
-object_edge |
-edge_radius |
-preferred_track |
-track_end_grid |
-fix_orientation |
-macro_by_color |
-user_grid
```

Data Types

obj_class string

Arguments

-enabled

Returns the current setting for the *set_snap_setting -enabled* command. Returns the value 1 if snapping is enabled, 0 if snapping is disabled. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

Feedback

`-class` *`obj_class`*

Returns the current setting for the *set_snap_setting -class class_name-snap object* command. Valid class values are std_cell, macro_cell, io_cell, metal_shape, edit_group, placement_constraint, wiring_constraint, or other. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-cursor_edge`

Returns the current setting for the *set_snap_setting -cursor_edge* command. Returns the value 1 if cursor should be snapped to visible object edges, otherwise returns the value 0. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-cursor_snap_type`

Returns the current setting for the *set_snap_setting -cursor_snap_type* command: either 'visible' if cursor should be snapped to visible object edges, or 'selectable' if cursor should be snapped to selectable objects only. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-object_edge`

Returns the current setting for the *set_snap_setting -object_edge* command: 1 if moved or stretched object should be snapped to other object edges, 0 if not. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-edge_radius`

Returns the current integer value setting for the *set_snap_setting -edge_radius* command, which specifies the search radius for snapping to object edges. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-preferred_track`

Returns the current setting for the *set_snap_setting -preferred_track* command. Returns the value 1 if only preferred tracks should be used when snapping to tracks is on, 0 otherwise. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*,

-track_end_grid -fix_orientation, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-track_end_grid`

Returns the current setting for the *set_snap_setting -track_end_grid* command. Returns the value 1 if track end grids should be considered as snapping targets, 0 otherwise. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-fix_orientation`

Returns the current setting for the *set_snap_setting -fix_orientation* command. Returns the value 1 if cell orientation should be fixed to match site rows or I/O guides, 0 otherwise. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-macro_by_color`

Returns the current setting for the *set_snap_setting -macro_by_color* command. Returns the value 1 if soft and hard macros should be snapped so that their colored pins are snapped to matching colored tracks, 0 otherwise. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

`-user_grid`

Returns the current setting for *set_snap_setting -user_grid* command. The command returns nothing if this option is not set. The *-enabled*, *-class*, *-cursor_edge*, *-cursor_snap_type* , *object_edge*, *-edge_radius*, *-preferred_track*, *-track_end_grid -fix_orientation*, *-macro_by_color*, and *-user_grid* options are mutually exclusive.

Description

The command queries the current snap settings in the GUI. You can only query one option at a time.

Examples

The following example returns 1 if snapping is enabled, 0 if snapping is disabled.

```
prompt> get_snap_setting -enabled
1
```

See Also

- set_snap_setting

Feedback

get_statements

Creates a collection of RTL Statements from the current design relative to the current instance. You can assign these statements to a variable or pass them into another command.

Syntax

collection *get_statements*

```
[-design design]
[-hierarchical]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-filter expression]
[-hsc separator]
[patterns
| -of_objects objects
```

Data Types

```
design          collection
exact_count     integer
minimum_count   integer
expression      string
separator       string
patterns        list
objects         list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

`-hierarchical`

Searches for statements level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a RTL statement RTL_CASE_1/adder, a hierarchical search finds it using "adder". This option is useful with *patterns*, but not with *-of_objects*.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This helps in searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error message is issued and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error message is issued and command processing stops.

`-expect_each_pattern_matches`

Expects each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error message is issued and command processing stops.

`-filter` *`expression`*

Filters the collection with *expression*. For any RTL statement that match *patterns* (or *objects*) the expression is evaluated based on the RTL statement attributes. If the expression evaluates to true, the RTL statement is included in the result.

`-hsc` *`separator`*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

Feedback

patterns

Matches RTL statement names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type RTL statement.

The *patterns* and *-of_objects* arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-of_objects *objects*

Creates a collection of RTL statements connected or associated to the specified objects. In this case, each object in the list is a name, pattern, or collection. The objects can be a cell, module and any other RTL statement.

The *patterns*, *-of_objects* arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Description

The *get_statements* command creates a collection of RTL statements in the current design, relative to the current instance, which match certain criteria. The command returns a collection, if any RTL statement matches the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, empty string is returned.

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design is not linked automatically.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, ensure the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_statements* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_statements* result to a variable.

When issued from the command prompt, *get_statements* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable *collection_result_display_limit*.

However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_statements* as an argument to *query_objects*.

Feedback

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the statements that begin with "RTL_CA". Although the output looks like a list, it is not. The output is just a display.

```
prompt> get_statements "RTL_CA*"
{"RTL_CASE_1", "RTL_CASE_2"}
```

See Also

- remove_statements

---

get_stub_chains

Returns a collection of stub chains from the current design.

Syntax

```
collection get_stub_chains
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
```

Data Types

```
design            collection
expression        string
exact_count       integer
minimum_count     integer
patterns          string
objects           list
```

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects are found in the current design.

Feedback

`-filter` *`expression`*

Filters the collection with *expression*. For any stub chain that matches the patterns option, the expression is evaluated based on the stub chain's attributes. If the expression evaluates to *true*, the stub chain is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for stub_chains level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`-of_objects` *`objects`*

Creates a collection containing the stub chains of the specified ports, pins or cells. Each object in the list is a name, pattern, or collection.

Feedback

patterns

Matches stub chains names against the *patterns* argument. The *patterns* argument can include the asterisk wildcard character (*).

The *patterns*, *-of_objects* arguments are mutually exclusive; you can specify only.

Description

The *get_stub_chains* command creates a collection of stub chains from the current design that match certain criteria. The command returns a collection of stub chains if any stub chain matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the *get_stub_chains* command at the command prompt, or you can nest it as an argument to another command, such as *report_stub_chains*. In addition, you can assign the *get_stub_chains* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the stub chains in the current design.

```
prompt> get_stub_chains
{stub1 stub2}
```

The following example returns a collection of all the stub chains associated with a specified pin.

```
prompt> get_stub_chains -of_objects u1/pin1
{stub1 stub2}
```

See Also

- create_stub_chain

---

get_supernets

Creates a collection of supernets from the netlist. You can assign these supernets to a variable or pass them into another command.

Syntax

collection *get_supernets*

```
[-design design]
[-hierarchical]
[-filter expression]
```

Feedback

```
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hsc separator]
patterns | -of_objects objects
```

Data Types

```
design          string
expression      string
exact_count     integer
minimum_count   integer
separator       character
patterns        list
objects         list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this option is not specified, objects will be found in the current design.

`-hierarchical`

Searches for supernets level-by-level relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX *find* command. For example, if there is a supernet block1/snet1, a hierarchical search finds it using "snet1". This option is useful with *patterns* but not with *-of_objects*.

`-filter` *expression*

Filters the collection with *expression*. For any supernets that match *patterns* (or *objects*), the expression is evaluated based on the attributes on the supernet. If the expression evaluates to true, the supernet is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Considers the *patterns* argument as true regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

Feedback

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

Specifies that each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hsc` *`separator`*

Specifies a separator character. The default is /. Valid values are /, @, ^, #, ., and |.

`-of_objects` *`objects`*

Creates a collection of supernets connected to the specified objects. Each object is either a named pin, a pin collection, a named cell, cell collection, a named net or a net collection, a named bundle or a bundle collection, a named routing corridor or a routing corridor collection. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

`patterns`

Matches supernet names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of type supernet. *patterns* and *-of_objects* are mutually exclusive; you must specify one, but not both.

Description

The *get_supernets* command creates a collection of supernets in the current design, relative to the current instance that match certain criteria. The command returns a collection if any supernets match the *patterns* or *objects* and pass the filter (if specified). If no objects matched the criteria, the empty collection is returned.

Feedback

If any *patterns* (or *objects*) fail to match any objects and the current design is not linked, the design automatically links.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_supernets* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_supernets* result to a variable.

When issued from the command prompt, *get_supernets* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *shell.common.collection_result_display_limit* application option.

The "implicit query" property of *get_supernets* provides a fast, simple way to display supernets in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_supernets* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the supernets that begin with 'SUPERNET' in block 'block1'. Although the output looks like a list, it is just a display.

```
prompt> get_supernets block1/SUPERNET
{"block1/NET1QNX", "block1/NET2QNX"}
```

The following example queries the supernets that are anchored to a collection of pins.

```
prompt> current_instance block1
block1
prompt> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{"o_reg1/QN", "o_reg2/QN"}
prompt> query_objects [get_supernets -of_objects $pinsel]
{"SUPERNET1QNX", "SUPERNET2QNX"}
```

---

get_supply_net_probability

Gets switching probability on selected supply nets in the current design.

Syntax

string *get_supply_net_probability*

```
[-scenarios scenario_list]
[-modes mode_list]
[-corners corner_list]
object_list
```

Data Types

```
scenario_list           list
mode_list               list
corner_list             list
object_list             list
```

Arguments

`-scenarios scenario_list`

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through *-modes* and *-corners* options. Output of the command is generated separately for each scenario. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command reports for the current scenario in the design.

`-modes mode_list`

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

`-corners corner_list`

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

Feedback

`object_list`

Specifies a supply net in the current design for which the value of the static probability are to be reported.

Description

Use this command to report the static probability of supply nets in the current design.

The supply nets that are reported can be specified explicitly as a list of objects.

If a combination of a mode and corner is specified that does not represent a valid scenario, those are ignored.

Examples

The following *get_supply_net_probablity* command reports the static probability on supply net VSS.

```
prompt> get_supply_net_probability [get_supply_net VSS]
(mode = default, corner = default, probability = 1, type = default)
```

---

get_supply_nets

Creates a collection of supply nets that meet the specified criteria.

Syntax

collection *get_supply_nets*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects objects]
[-top_net_of_hierarchical_group]
```

Feedback

```
[-segments]
[[patterns]
```

Data Types

```
expression      string
exact_count     int
minimum_count   int
objects         list
patterns        list
```

Arguments

`-hierarchical`

Searches for supply nets in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply nets only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply net names relative to the current scope.

You cannot specify this option when you use the *-of_objects* option.

`-filter expression`

Filters the collection with *expression*. For any supply nets that match *patterns*, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

`-expect exact_count`

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Returns a collection of supply nets associated with the specified objects. The objects can be supply ports, pg leaf pins, voltage_areas, or supply sets.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

`-top_net_of_hierarchical_group`

Keeps only the top supply_net of a hierarchical group. When more than one hierarchical supply_net of the same group is specified (equivalent supply_net at various hierarchical levels), only the supply_net closest to the top of the hierarchy is saved with the collection. In the case of multiple supply_nets at the same level, the first supply_net specified is kept. Although this option can be used when there are multiple nets specified, it is best used in combination with *-segments* and with a single supply_net.

`-segments`

Returns all equivalent supply_nets for given supply_nets. This modifies the initial search which matches *patterns* or *objects*. It is applied after filtering, but before the *-top_net_of_hierarchical_group* is determined. For each net, all equivalent supply_nets will be added to the result collection. Although this option can be used with other options and when there are multiple supply_nets specified, it is best used with a single net. When combined with the *-top_net_of_hierarchical_group* option, you can isolate the highest scope of equivalent supply_net.

`patterns`

Matches supply net names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses "*".

Feedback

Description

The *get_supply_nets* command creates a collection of supply nets in the current design, that match certain criteria. If no supply nets match the criteria, an empty string is returned.

Until the *commit_upf* command is executed and power intent is finalized, supply nets of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using *-regexp*, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_supply_nets* command at the command prompt, or you can nest it as an argument to another command, such as *report_supply_nets*. In addition, you can assign the *get_supply_nets* result to a variable.

When issued from the command prompt, *get_supply_nets* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by setting the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example gets all supply nets under the current scope.

```
prompt> get_supply_nets -hierarchical
{"VDD", "SUB_INST/VDD"}
```

See Also

- create_supply_net
- report_supply_nets
- shell.common.collection_result_display_limit

---

get_supply_ports

Creates a collection of supply ports that meet the specified criteria.

Syntax

collection *get_supply_ports*

Feedback

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects objects]
[-exclude_power_switch]
[[patterns]
```

Data Types

```
expression      string
exact_count     int
minimum_count   int
objects         list
patterns        list
```

Arguments

`-hierarchical`

Searches for supply ports in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply ports only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply port names relative to the current scope.

You cannot specify this option when you use the *-of_objects* option.

`-filter expression`

Filters the collection with *expression*. For any supply ports that match *patterns*, the expression is evaluated based on the supply port's attributes. If the expression evaluates to true, the supply port is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Returns a collection of supply ports associated with the specified supply net objects.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

`-exclude_power_switch`

Exclude the supply ports of power switches. By default, supply ports of power switches are included in the result.

`patterns`

Matches supply port names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses "*".

Description

The *get_supply_ports* command creates a collection of supply ports in the current design, that match certain criteria. If no supply ports match the criteria, an empty string is returned.

Until commit_upf command is executed and power intent is finalized, supply ports of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using *-regexp*, take care in the way you quote the patterns and filter expression. Use rigid

Feedback

quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_supply_ports* command at the command prompt, or you can nest it as an argument to another command, such as *report_supply_ports*. In addition, you can assign the *get_supply_ports* result to a variable.

When issued from the command prompt, *get_supply_ports* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example gets all supply ports under the current scope.

```
prompt> get_supply_ports -hierarchical
{"VDD", "SUB_INST/VDD"}
```

See Also

---

get_supply_sets

Creates a collection of supply sets that meet the specified criteria.

Syntax

collection *get_supply_sets*

```
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
```

Feedback

```
[-of_objects objects]
[[patterns]
```

Data Types

```
expression      string
exact_count     int
minimum_count   int
objects         list
patterns        list
```

Arguments

`-hierarchical`

Searches for supply sets in the current scope and all of its descendant scopes. If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply sets only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply net names relative to the current scope.

You cannot specify this option when you use the *-of_objects* option.

`-filter expression`

Filters the collection with *expression*. For any supply sets that match *patterns*, the expression is evaluated based on the attributes of the supply set. If the expression evaluates to true, the supply set is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

`-expect exact_count`

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Returns a collection of supply sets associated with the specified objects. The objects can be power domains and supply nets.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses a pattern of "*".

`patterns`

Matches supply set names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, refer to the *wildcards* man page.

The *patterns* argument and *-of_objects* option are mutually exclusive. If you do not specify either, the tool uses "*".

Description

The *get_supply_sets* command creates a collection of supply sets in the current design, that match certain criteria. If no supply sets match the criteria, an empty string is returned.

Until commit_upf command is executed and power intent is finalized, supply sets of subblocks are not propagated and will not be included in the result.

Regular expression matching is the same as in the Tcl regexp command. When using *-regexp*, take care in the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_supply_sets* command at the command prompt, or you can nest it as an argument to another command, such as *report_supply_sets*. In addition, you can assign the *get_supply_sets* result to a variable.

When issued from the command prompt, *get_supply_sets* behaves as though *query_objects* has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum by using the *shell.common.collection_result_display_limit* application option.

Feedback

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example gets all supply sets under the current scope.

```
prompt> get_supply_sets
{SS1 SS2 SS3 SS4 SS5 new_sset_1}
```

The following example gets all supply sets matching a given pattern.

```
prompt> get_supply_sets SS*
{SS1 SS2 SS3 SS4 SS5}
```

- report_supply_sets
- shell.common.collection_result_display_limit

---

get_svf

Get the name of the current SVF directory.

Syntax

```
boolean get_svf
```

Description

This command prints the name of the SVF directory that is currently open for recording SVF guidance for Formality. If no SVF directory has been specified using the *set_svf* command, a message is printed.

Examples

In this example, we query the name of the SVF directory and find out that setup information is not being recorded yet. Then we specify the directory name and repeat the query.

```
prompt> get_svf
SVF guidance is not enabled.
1
prompt> set_svf cache_ctrl_svf
1
prompt> get_svf
The current SVF directory is /project/chip/cache_ctrl/cache_ctrl_svf.
1
```

Feedback

See Also

- set_svf

---

get_switching_activity

Gets switching activity information on nets, pins, ports and cells in the current design.

Syntax

string *get_switching_activity*

```
[-state_condition state_condition]
[-path_sources path_sources]
[-rise]
[-fall]
[-related_clock]
[-scenarios scenario_list]
[-modes mode_list]
[-corners corner_list]
object_list
```

Data Types

state_condition	string
path_sources	list
scenario_list	list
mode_list	list
corner_list	list
object_list	list

Arguments

`-state_condition state_condition`

Specifies the state condition for reporting state-dependent activities. State dependent activities can be reported when the object is already annotated with state-dependent activities. The state condition specified with this argument must match to a state condition already annotated for this object. Use -state_condition default to specify the default state condition.

`-path_sources path_sources`

Specifies the path sources when reporting path-dependent activities. This can be used when the object is already annotated with path-dependent activities. The path sources specified with this argument must be the same as those annotated for this object. If -path_sources option is used to specify the path_sources value, then -state_condition option must be specified to specify the value of the path_sources.

Feedback

`-rise`

This option is used with the *-state_condition* option. It reports rise transition.

`-fall`

This option is used with the *-state_condition* option. It reports fall transition.

`-related_clock`

This option is used to print the clock domain of the objects.

`-scenarios` *`scenario_list`*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through *-modes* and *-corners* options. Output of the command is generated separately for each scenario. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command reports for the current scenario in the design.

`-modes` *`mode_list`*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

`-corners` *`corner_list`*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

`object_list`

Specifies a net, pin, port or cell in the current design for which the values of static probability, the toggle rate and the type of activity are to be reported.

Description

This command is used to report switching activity information on nets, ports, pins and cells. Switching activity information includes toggle rate, static probability and activity type.

Note that *object_list* argument should always be provided to the command. The activity type reported by the command can only be one of 'annotated', 'simulated', 'propagated', 'sta' or 'default'.

For more statistics on the switching activity annotation on the current design, use the *report_activity* command.

Feedback

Examples

The following *get_switching_activity* command reports the toggle rate and static probability values on a pin for the current scenario in the design.

```
prompt> get_switching_activity {H1/p1}
 (mode = default, corner = default, probability = 0.9, toggle_rate = 0.3,
 type = annotated)
```

The following *get_switching_activity* command reports the activity information for a list of objects for the default state_condition for the current scenario scn1. If the object_list contains nets then the tool will ignore the state_condition option for those nets.

```
prompt> get_switching_activity {H1 H1/p1 H1/n1} -state_condition default
scn1 {{condition default probability 1}}
scn1 {{condition default rise_toggle_rate 0 fall_toggle_rate 0}}
(mode = scn1.mode, corner = scn1.corner, probability = 0.5,
toggle_rate = 0.0333333, type = default)
```

See Also

- read_saif
- report_power
- report_activity
- reset_switching_activity
- set_switching_activity

---

get_taps

Retrieves a collection of tap objects.

Syntax

collection *get_taps*

```
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
```

Feedback

Data Types

```
string expression
list patterns
int exact_count
int minimum_count
```

Arguments

`-filter` *`expression`*

Filters the collection with the value specified by expression. For any taps that match the *patterns* argument, the expression is evaluated based on the specified tap attributes. If the expression is evaluated to be true, the tap is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Uses the value of the pattern arguments as real regular expressions rather than simple wildcard patterns. This option also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions, rather than with simple wildcard patterns. Note that the -regexp and -exact options are mutually exclusive.

`-nocase`

Makes the pattern matching case-insensitive.

`-exact`

Disables the simple pattern matching. This is used when searching for objects that contain wildcard characters, like asterisks (*) and question marks (?) symbols. The -exact and -regexp options are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

Matches each pattern in *patterns* at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

Feedback

patterns

Matches tap names against patterns. Patterns can include wildcard characters asterisks (*) and question marks (?) symbols or regular expressions, depending on the use of the -regexp option.

Description

The *get_taps* command retrieves a collection of taps that are currently in the session context of the current design. The command returns a collection of the taps that match the patterns and pass the filter criteria (if specified). If no object matches the criteria, an empty collection is returned.

Use the -regexp option to enable regular expression matching in the same way as using the TCL regexp command. When using the -regexp option, be careful of the way you quote the patterns and filter expression. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression matching begins at the beginning of an object name and stops at the end of an object name. You can widen the search simply by adding the period and asterisk symbols (.*) to the beginning or end of the expressions as needed.

You can use the *get_taps* command at the command prompt, or nest it as an argument to another command, like the *query_objects* command. In addition, you can assign the result of the *get_taps* run to a variable.

When issued from the command prompt, the *get_taps* command behaves as though the *query_objects* command has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. To change the setting, use the *collection_result_display_limit* variable.

The "implicit query" property of the *get_taps* command provides a fast and simple way to display cells in a collection. However, if you want the flexibility provided by *query_objects* (for example, if you want to display the object class), use the *get_taps* command as an argument to the *query_objects* command.

Examples

The following example queries all taps that match a pattern TAP?2, except for the TAP_42.

```
prompt> get_taps -filter full_name!=TAP_42 TAP_?2
{"TAP_12", "TAP_22", "TAP_32", "TAP_52"}
```

The following example queries all taps.

```
prompt> get_taps

{"TAP_1", "TAP_2", "TAP_3", "TAP_4"}
```

Feedback

See Also

- create_taps
- remove_taps
- report_taps

---

get_techs

Creates a collection of technology data objects loaded into memory. You can assign these technology data objects to a variable or pass them into another command.

Syntax

```
collection get_techs
[-all]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects objects]
```

Data Types

```
expression string
objects    list
patterns   list
```

Arguments

`-all`

Returns the technology data objects of both the explicitly opened libraries and their reference libraries.

By default, the command returns only the technology data objects of the explicitly opened libraries.

`-filter expression`

Filters the collection with *expression*.

For any technology data objects that match *patterns* (or *objects*), the expression is evaluated based on the technology data object's attributes. If the expression evaluates to true, the technology data object is included in the result.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modify the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns.

The *-regexp* and *-exact* options are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters.

The *-exact* and *-regexp* options are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`objects`*

Creates a collection of technology data objects of the specified objects. In this case, each object is either a library or a block collection. In case of block, the technology data object of the containing library will be returned. *-of_objects* and *patterns* are mutually exclusive; you must specify one, but not both.

`patterns`

Matches technology data object names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

Feedback

Description

The *get_techs* command creates a collection of technology data objects from those currently loaded into memory that match certain criteria. The command returns a collection if any of the technology data objects match the *patterns* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_techs* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_techs* result to a variable.

When issued from the command prompt, *get_techs* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the *shell.common.collection_result_display_limit* application option.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example creates a technology data object in the specified library. The following *get_techs* command returns the created technology data object.

```
prompt> create_tech -library r4000 tcbn90g
{r4000}
prompt> get_techs -of_objects [get_libs r4000]
{tcbn90g}
```

The following example replaces the existing technology data object by creating a new technology data object in the current library. The following *get_techs* command returns the created technology data object.

```
prompt> create_tech -force tcbn90g
{tcbn90g}
prompt> get_techs -of_objects [current_lib]
{tcbn90g}
```

---

get_terminals

Creates a collection by selecting terminals from the design.

Syntax

collection *get_terminals*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_lib_cell]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
of_objects	list
patterns	list
region	list
point	list

Feedback

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with the specified expression. For each terminal in the collection, the expression is evaluated based on the terminal's attributes. If the expression evaluates to true, the terminal is included in the result.

To see the list of terminal attributes that you can use in the expression, use the *list_attributes -application -class terminal* command.

For more information about how to use the *-filter* option, see the *filter_collection* man page.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive. use only one.

`-nocase`

Makes matches case-insensitive, both for the *patterns* argument and for the ==, =~, and !~ filter operators.

`-exact`

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The *-regexp* and *-exact* options are mutually exclusive; you can use only one.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for terminal level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-include_lib_cell`

Search for terminals in the *lib_cell*. By default, *lib_cell* vias are excluded from search.

This option must be used with the *-hierarchical* option.

`patterns`

Creates a collection of terminals whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the *wildcards* man page. Pattern matching is case sensitive unless you use the *-nocase* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-of_objects` *`port_list`*

Creates a collection of terminals connected to the specified ports.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all terminals at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all terminals that are completely inside the specified region and doesn't include terminals which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all terminals that are completely inside the specified region and the terminals which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all terminals which are abut/touching from inside or outside to the specified region and the terminals whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of terminals by selecting terminals from the specified design or the current design.

The command returns a collection if any terminals match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as *get_attribute*. In addition, you can assign the result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of terminals named reset or with a prefix of clock:

```
prompt> get_terminals [list reset clock*]
{reset clock}
```

The following example creates a collection of terminals with attribute filtering.

Feedback

```
prompt> get_terminals  -filter {port_name == reset}
{reset}
```

The following example creates a collection of all terminals belonged to the port "reset".

```
prompt> get_terminals -of_objects {reset}
{reset}
```

- wildcards

---

get_timing_arcs

Creates a collection of timing arcs for custom reporting and other processing.

Syntax

collection *get_timing_arcs*

```
[-design design]
[-to to_list]
[-from from_list]
[-of_objects object_list]
[-filter expression]
[-quiet]
[-expect exact_count]
[-expect_at_least minimum_count]
```

Data Types

design	collection
to_list	list
from_list	list
object_list	list
expression	string
exact_count	integer
minimum_count	integer

Feedback

Arguments

`-design` *design*

Specifies the top-level design for finding objects.

By default, objects are found in the current design.

`-to` *to_list*

Specifies the to pins or to ports to get the timing arcs for. All backward arcs from the specified pins or ports are considered.

You must specify one of the following options: *-to*, *-from*, or *-of_objects*.

`-from` *from_list*

Specifies the from pins or from ports to get the timing arcs for. All forward arcs from the specified pins or ports are considered.

You must specify one of the following options: *-to*, *-from*, or *-of_objects*.

`-of_objects` *object_list*

Specifies the cells or nets for which to get the timing arcs. If you specify a cell, all cell arcs of that cell are considered. If you specify a net, all net arcs of that net are considered.

You must specify one of the following options: *-to*, *-from*, or *-of_objects*.

`-filter` *expression*

Filters the collection with the specified expression.

For any objects that match, the command evaluates the expression based on the timing arc's attributes. If the expression evaluates to true, the timing arc is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-expect` *exact_count*

Specifies the expected number of objects to find. If the command finds a different number of objects, it raises a Tcl error and stops processing.

`-expect_at_least` *minimum_count*

Specifies the minimum number of objects to find. If the command finds fewer objects, it raises a Tcl error and stops processing.

Feedback

Description

The *get_timing_arcs* command creates a collection of timing arcs for custom reporting or other operations. Use the *foreach_in_collection* command to iterate among the arcs in the collection. You can use the *get_attribute* command to obtain information about the timing arcs. You can also use a filter expression to filter the arcs that satisfy the specified conditions. To see the attributes supported on timing arcs, use the *list_attributes -application -class timing_arc* command.

Multicorner-Multimode Support

This command works only on the mode associated with the current scenario.

Examples

The following example reports the to-pin and from-pin for the timing arcs of the ffa cell.

```
prompt> set arcs [get_timing_arcs -of_objects [get_cells ffa]]
prompt> foreach_in_collection arc $arcs {
?   set fpin [get_attribute $arc from_pin]
?   set tpin [get_attribute $arc to_pin]
?   set from_pin_name [get_attribute $fpin full_name]
?   set to_pin_name [get_attribute $tpin full_name]
?   echo $from_pin_name -> $to_pin_name
?  }
ffa/CP -> ffa/D
ffa/CP -> ffa/D
ffa/CP -> ffa/Q
ffa/CP -> ffa/QN
ffa/CD -> ffa/Q
ffa/CD -> ffa/QN
```

Feedback

Arguments

`-from` *`from_list`*

Specifies a list of from pins, ports, cells, or clocks to be processed. Path startpoints are typically the input ports or clock pins of registers. If you specify a clock, all startpoints are considered if they are clocked by the clock.

`-rise_from` *`rise_from_list`*

Same as the *-from* option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-fall_from` *`fall_from_list`*

Same as the *-from* option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-to` *`to_list`*

Specifies a list of to pins, ports, cells, or clocks to be processed. Path endpoints are typically the output ports or data pins of registers. If you specify a clock, all endpoints are considered if they are constrained by the clock.

`-rise_to` *`rise_to_list`*

Same as the *-to* option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

`-fall_to` *`fall_to_list`*

Same as the *-to* option,but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

`-through` *`through_list`*

Specifies a list of through pins, ports, cells, or nets to be processed. Only paths through the named objects are considered.

You can specify many *through_list* groups by using multiple *-through* options. The objects specified within one *-through* option are assumed to be in OR mode. The group of objects specified with multiple *-through* options is assumed to be in AND mode.

Feedback

If you specify *-through* only one time, the tool generates only the paths that travel through one or more of the objects in the list.

If you specify multiple *-through* options, the tool generates only the paths that travel through one or more of the objects in each list. the tool uses the exact order in which the *-through* options are listed; so to obtain correct results, you must ensure that this order is the same as that followed by the actual paths in the circuit.

`-rise_through` *`rise_through_list`*

Similar to the *-through* option, except that the path must rise through the objects specified.

`-fall_through` *`fall_through_list`*

Similar to the *-through* option, except that the path must fall through the objects specified.

`-exclude` *`exclude_list`*

Excludes all data paths from, through, or to specified list of pins, ports, nets, and cell instances. If a cell instance is specified, all pins of the cell are excluded. The *-exclude* option

o Takes precedence over the *-from*, *-through*, and *-to* options.

o Is exclusive with the *-rise_exclude* and *-fall_exclude* options.

o Does not apply to borrowing path from the *-trace_latch_borrow* option or clock path from the *-path full_clock* or *full_clock_expanded* option.

Note that this option is intended for use in conjunction with *-from*, *-through* and *-to* options and can lead to long runtime when used on its own, i.e. without other such topological options.

`-rise_exclude` *`rise_exclude_list`*

This option is the same as the *-exclude* option, but applies only to paths rising at the named pins, ports, nets, or cell instances.

`-fall_exclude` *`fall_exclude_list`*

This option is the same as the *-exclude* option, but applies only to paths falling at the named pins, ports, nets, or cell instances.

`-delay_type max | min | min_max | max_rise | max_fall | min_rise | min_fall`

Specifies the type of path delay. Valid values are *max* (the default), *min*, *min_max*, *max_rise*, *max_fall*, *min_rise*, or *min_fall*. The "rise" or "fall" suffix in the delay type refers to a rising or falling transition at the path endpoint.

Feedback

`-path_type full_clock | full_clock_expanded`

Specifies the structure of the generated timing path objects. The allowed values are *full_clock* and *full_clock_expanded*, which create clock objects for the timing_path's *launch_clock_paths* and *capture_clock_paths* attributes. The *full_clock_expanded* value creates clock path objects that include the path between a primary clock and related generated clocks.

`-report_by design | mode | corner | scenario | group`

Specifies the grouping criteria for generating paths. The default is *design*. It is an error to specify both the *-report_by* and *-sort_by* options.

`-sort_by group | slack`

Specifies the sorting criteria for generating paths. Valid values are: *group* or *slack*. It is an error to give both the *-report_by* and *-sort_by* options. This option is deprecated, use the *-report_by* option instead.

`-nworst` *`paths_per_endpoint`*

Retrieves the *n* worst paths to endpoint, where *paths_per_endpoint* is >= 1. The default is 1, meaning that only the worst path to an endpoint is considered. Specifying larger values of *paths_per_endpoint* increases runtime.

`-max_paths` *`max_path_count`*

Specifies the maximum number of paths to retrieve per path group, where *max_path_count* is >= 1. The default is 1.

`-slack_lesser_than` *`lesser_slack_limit`*

Retrieves only paths with a slack less than *lesser_slack_limit*. With this filtering in effect, it might not be possible to find enough paths to satisfy the *-max_paths* and *-nworst* parameters. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not have a defined slack.

`-pba_mode none | path | exhaustive`

Specifies one of the following path-based analysis modes:

- *none* - Disables path-based analysis.
- *path* - Performs path-based analysis on paths after they have been gathered.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the worst path-based analysis path set in the design. You cannot use the *exhaustive* mode together with the *-start_end_pair* or option.

Feedback

`-start_end_type` *`from_to_type`*

Restricts the collection to one of four classes of paths based on the type of startpoint and endpoint:

- *reg_to_reg* - from register to register
- *reg_to_out* - from register to output port
- *in_to_reg* - from input port to register
- *in_to_out* - from input port to output port

In this description, "register" means any valid startpoint or endpoint that is not an input port, output port, or bidirectional port, even if not a sequential register. For example, a clock-gating check endpoint qualifies as a "register" in the *in_to_reg* from-to type. A bidirectional port qualifies as both an input port and an output port.

`-start_end_pair`

Retrieves paths for each pair of startpoint and endpoint based on connectivity. This option can lead to long runtime and can lead to generating a huge number of paths depending on the design. By default, this option searches only for paths that are violating. This default can be changed by having an explicit -slack_lesser_than option. The options that do not work with this option are -nworst, -max_paths, -report_by. Unlike other options of the get_timing_paths command, this option causes the paths returned to no longer be sorted based on slack. Instead, paths are arranged based on the endpoint with those sharing the same endpoint appearing next to one another. The maximum number of paths returned is limited to 2000000.

`-modes` *`mode_list`*

Specifies the modes for which to generate paths. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option will be processed. If this option is not given, the command will process scenarios of all modes. If none of the *-modes*, *-corners*, or *-scenarios* options are given, the command will process every active scenario of the design. It is an error to give this option with the *-scenarios* option.

`-corners` *`corner_list`*

Specifies the corners for which to generate paths. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option will be processed. If this option is not given, the command will process every scenario that is active with the specified mode(s). It is an error to give this option with the *-scenarios* option.

Feedback

`-scenarios` *`scenario_list`*

Specifies the scenarios for which to generate paths. Each of the specified scenarios is processed. It is an error to give this option with the *-modes* or the *-corners* options. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, every scenario of the design will be processed.

`-groups` *`group_list`*

Specifies the list of path group names for generating paths. The default is all path groups. If this option is specified, unconstrained paths will not be returned, as unconstrained paths do not belong to any path group.

`-exception` *`exception_type`*

Prints user-specified timing exceptions, namely false paths, multicycle paths, and minimum and maximum delays, that are satisfied per timing path being reported. Only "dominant" exception type is acceptable, which is to report the dominant exception constraint used for the reported path.

Note: The additional analysis required per path with the -exceptions option is not trivial. Therefore, using a report_timing command with the -exceptions option is expected to execute slower than the exact same command without this option. The -exceptions option does not work with -path_type short/end/end_detailed option and forces the -input_pins option.

`-include_hierarchical_pins`

Includes any hierarchical pins that the generated paths pass through. By default, the paths include only ports and actual leaf cell driver and load pins. If a hierarchical pin is a path start or end point, it will of course always be included.

Description

The *get_timing_paths* command creates a collection of timing path objects for custom reporting or other operations. Use the *foreach_in_collection* command to iterate among the timing paths in the collection. You can use the *get_attribute* and *collection* commands to obtain information about the timing paths. A collection of timing_paths can easily be printed by passing it to the *report_timing* command.

If the *time.report_unconstrained_paths* application option is set to *true*, the command will search for unconstrained paths to endpoints for which constrained paths cannot be found. Searching for unconstrained paths can cause significantly longer runtimes.

The following attributes are among those supported on timing path objects:

```
arrival
capture_clock_paths
check_value
clock_uncertainty
common_path_pessimism
```

Feedback

Feedback

Note that the launch_clock_paths and capture_clock_paths attributes are set only if specified by the *-path_type* option.

The following attributes are among those supported on clock_path objects:

```
clock
clock_edge_type
clock_edge_value
clock_latency
clock_name
corner
corner_name
design_name
driving_cell_adjustment
endpoint
endpoint_name
full_name
lib_name
mode

source_clock
source_clock_edge_type
source_clock_edge_value
source_clock_name
source_latency
startpoint
startpoint_name
```

One attribute of a timing path or clock path is the *points* collection. A timing point object corresponds to a pin or port along the path. Iterate through these points with *foreach_in_collection* and get attributes on them by using the *get_attribute* command. The following attributes are among those for timing points of a timing path or clock path:

```
arrival
capacitance
delay
delta_delay
fanout
full_name
name
object
object_class
object_name
rise_fall
transition
```

Feedback

For information about creating collections and iterating over the elements of a collection, see the *collections* and *foreach_in_collection* man pages.

For a complete list and descriptions of the attributes on timing_path, clock_path, and timing_port objects, see the *timing_path_attributes*, *clock_path_attributes*, and *timing_point_attributes* man pages.

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following command returns the two worst timing paths that rise from reg/latch/CP with slack less than 20.0.

```
prompt>  get_timing_paths -nworst 2 -path_type full_clock -permanent \\
   -rise_from reg/latch/CP -slack_lesser_than 20.0 -report_by group
```

If you use the *-pba_mode* option, path recalculation (path-based analysis) is used during the path search, and the worst recalculated paths meeting your criteria are returned. This option requires that a path search is performed to ensure that the paths being returned truly are the worst paths. The additional runtime required for this option depends on the amount of timing improvement resulting from path-based analysis. As the timing improvement from path-based analysis increases, the runtime for the path search increases. Large *-nworst* values can significantly increase the time needed for the search.

Feedback

get_topological_constraints

Creates a collection of topological pin feedthrough constraints from the current design.

Syntax

```
collection get_topological_constraints
[-hierarchical]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-hierarchical`

Returns topological pin constraints for the entire design hierarchy. By default, the command returns constraints for the current level.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the topological constraint attributes. You can determine the topological constraint attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topological constraint is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

Feedback

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection containing the topological constraints associated with the specified objects. The objects can be constraint owner objects of type net/bundle, or the objects can be the start/end objects. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches the topological constraint names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the *pattern*.

Description

This command creates a collection of topological constraints from the current design that match certain criteria. The command returns a collection handle (identifier) if any topological constraints match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

Feedback

You can use the *get_topological_constraints* command at the command prompt or nest it as an argument to another command (such as *report_topological_constraint*). You can also assign the *get_topological_constraints* result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example returns the topological constraints from the current_design

```
prompt> get_topological_constraints
{TPF_CONSTRAINT_0 TPF_CONSTRAINT_1 TPF_CONSTRAINT_3 TPF_CONSTRAINT_4}
```

The following example returns the topological constraints owned by net \'net1\'

```
prompt> get_topological_constraints -of_objects net1
{TPF_CONSTRAINT_1 TPF_CONSTRAINT_3}
```

The following example returns the topological constraints that have the 'start_sides' attribute set

```
prompt> get_topological_constraints -filter "start_sides!=\\"\\""
{TPF_CONSTRAINT_1 TPF_CONSTRAINT_4}
```

See Also

- create_topological_constraint
- remove_topological_constraints
- report_topological_constraints

---

get_topology_edges

Creates a collection by selecting topology edges from the current block.

Syntax

collection *get_topology_edges*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Feedback

Data Types

expression	string
design_name	string
exact_count	integer
minimum_count	integer
patterns	list
of_objects	list

Arguments

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology edge attributes. You can determine the topology edge attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topology edge is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design` *design_name*

Specifies the design module in which to search for topology edges.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

Feedback

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for topology edges level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the topology edge names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the topology edges that are associated with the specified objects.

If the objects are topology nodes, the command returns the topology edges which the topology nodes are connected to, i.e. the set of topology edges which have the specified topology nodes as their start_node or end_node.

If the objects are topology groups, the command returns the topology edges owned by the topology plans owned by the groups.

If the objects are topology plans, the command returns the topology edges owned by the plans.

If the objects are topology repeaters, the command returns the topology edges which own the repeaters.

If the objects are nets, supernets, or bundles, the command returns the topology edges that have one or more of those objects in their "objects" attribute collection.

If the objects are constraint groups, the command returns the topology edges which are members of the specified constraint groups.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Feedback

Description

This command creates a collection of topology edges that meet the selection criteria. It returns a collection handle if one or more topology edges meet the selection criteria. If no topology edges match the selection criteria, it returns an empty string.

You can use the *get_topology_edges* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of topology_edges by matching the name against the pattern:

```
prompt> get_topology_edges TOPOLOGY_EDGE*
{curplan/TOPOLOGY_EDGE0 curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2}
```

The following example creates a collection of all topology_edges:

```
prompt> get_topology_edges *
{curplan/TOPOLOGY_EDGE0 curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2
 plan0/medge0 plan0/medge1}
```

The following example creates a collection of all topology_edges connected to topology_node "mynode":

```
prompt> get_topology_edges -of_objects [get_topology_nodes mynode]
{curplan/TOPOLOGY_EDGE1 curplan/TOPOLOGY_EDGE2}
```

See Also

---

get_topology_groups

Creates a collection by selecting topology groups from the current block.

Feedback

Syntax

collection *get_topology_groups*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the topology group attributes. You can determine the topology group attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topology group is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design` *design_name*

Specifies the design module in which to search for topology groups.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for topology groups level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the topology group names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the topology groups that are associated with the specified objects.

If the objects are topology plans, the command returns the topology groups which own those plans.

If the objects are topology nodes or topology edges, the command returns the topology groups that own the plans owning those nodes and edges.

If the objects are topology_repeaters, the command returns the topology groups, which own the plans owning the edges that own the repeaters.

Each object in the list is a name, pattern, or collection.

Feedback

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Description

This command creates a collection of topology groups that meet the selection criteria. It returns a collection handle if one or more topology groups meet the selection criteria. If no topology groups match the selection criteria, it returns an empty string.

You can use the *get_topology_groups* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of topology_groups by matching the name against the pattern:

```
prompt> get_topology_groups TOPOLOGY_GROUP*
{TOPOLOGY_GROUP0 TOPOLOGY_GROUP1 TOPOLOGY_GROUP2}
```

The following example creates a collection of all topology_groups:

```
prompt> get_topology_groups *
{mygroup0 mygroup1 TOPOLOGY_GROUP0 TOPOLOGY_GROUP1 TOPOLOGY_GROUP2}
```

---

get_topology_nodes

Creates a collection by selecting topology nodes from the current block.

Syntax

collection *get_topology_nodes*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
```

Feedback

```
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects | -of_ref_nodes node_list]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
node_list       list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology node attributes. You can determine the topology node attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topology node is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design design_name`

Specifies the design module in which to search for topology nodes.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect exact_count`

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for topology nodes level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the topology node names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the topology nodes that are associated with the specified objects.

If the objects are topology edges, the command returns the topology nodes which are connected as endpoints of the objects, i.e. the set of topology nodes which are either the start_node or end_node of the specified topology edges.

If the objects are topology_plans, the command returns the topology nodes owned by the plans.

If the objects are topology groups, the command returns the topology nodes owned by the topology plans owned by the groups.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`-of_ref_nodes` *`node_list`*

Creates a collection topology nodes that reference the nodes in *node_list*.

Feedback

Description

This command creates a collection of topology nodes that meet the selection criteria. It returns a collection handle if one or more topology nodes meet the selection criteria. If no topology nodes match the selection criteria, it returns an empty string.

You can use the *get_topology_nodes* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of topology_nodes by matching the name against the pattern:

```
prompt> get_topology_nodes TOPOLOGY_NODE*
{curplan/TOPOLOGY_NODE0 curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2}
```

The following example creates a collection of all topology_nodes:

```
prompt> get_topology_nodes *
{curplan/TOPOLOGY_NODE0 curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2
 plan0/mnode0 plan0/mnode1}
```

The following example creates a collection of all topology_nodes that are endpoints of a collection of topology_edges:

```
prompt> get_topology_nodes -of_objects [get_topology_edges myedge*]
{curplan/TOPOLOGY_NODE1 curplan/TOPOLOGY_NODE2}
```

---

get_topology_plans

Creates a collection by selecting topology plans from the current block.

Feedback

Syntax

collection *get_topology_plans*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology plan attributes. You can determine the topology plan attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topology plan is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design` *design_name*

Specifies the design module in which to search for topology plans.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for topology plans level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the topology plan names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the topology plans that are associated with the specified objects.

If the objects are topology groups, the command returns the topology plans owned by the groups.

If the objects are topology nodes or topology edges, the command returns the topology plans own those nodes and edges.

If the objects are topology_repeaters, the command returns the topology plans which own the edges that own the repeaters.

If the objects are nets, supernets, or bundles, the command returns the topology plans that have one or more of those objects in their "objects" attribute collection.

Feedback

Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Description

This command creates a collection of topology plans that meet the selection criteria. It returns a collection handle if one or more topology plans meet the selection criteria. If no topology plans match the selection criteria, it returns an empty string.

You can use the *get_topology_plans* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of topology_plans by matching the name against the pattern:

```
prompt> get_topology_plans TOPOLOGY_PLAN*
{TOPOLOGY_PLAN0 TOPOLOGY_PLAN1 TOPOLOGY_PLAN2}
```

The following example creates a collection of all topology_plans:

```
prompt> get_topology_plans *
{myplan0 myplan1 TOPOLOGY_PLAN0 TOPOLOGY_PLAN1 TOPOLOGY_PLAN2}.in -0.25in
```

See Also

- create_topology_plan
- remove_topology_plans
- current_topology_plan

---

get_topology_repeaters

Creates a collection by selecting topology repeaters from the current block.

Syntax

collection *get_topology_repeaters*

```
[-filter expression]
[-quiet]
[-design design_name]
[-regexp]
[-nocase]
```

Feedback

```
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns | -of_objects of_objects]
```

Data Types

```
expression      string
design_name     string
exact_count     integer
minimum_count   integer
patterns        list
of_objects      list
```

Arguments

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the topology repeater attributes. You can determine the topology repeater attributes by using the *list_attributes* command. If the expression evaluates to *true*, the topology repeater is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-design design_name`

Specifies the design module in which to search for topology repeaters.

`-regexp`

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing stops.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing stops.

`-expect_each_pattern_matches`

Checks that each pattern in *patterns* matches at least one object. If one or more patterns does not match, a Tcl error is raised and command processing stops.

`-hierarchical`

Searches for topology repeaters level-by-level relative to the current instance. Use this option with *patterns* and not with the *-of_objects* option.

`patterns`

Matches the topology repeater names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses asterisk (*) as the pattern.

`-of_objects` *`of_objects`*

Creates a collection containing the topology repeaters that are associated with the specified objects.

If the objects are topology edges, the command returns the topology repeaters which are owned by the edges.

If the objects are topology plans, the command returns the topology repeaters owned by the topology edges owned by the plans.

If the objects are topology groups, the command returns the topology repeaters owned by the topology edges owned by the topology plans owned by the groups.

Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

Feedback

Description

This command creates a collection of topology repeaters that meet the selection criteria. It returns a collection handle if one or more topology repeaters meet the selection criteria. If no topology repeaters match the selection criteria, it returns an empty string.

You can use the *get_topology_repeaters* command at the command prompt, use it as an argument nested in another command, or assign its result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following example creates a collection of topology_repeaters by matching the name against the pattern:

```
prompt> get_topology_repeaters TOPOLOGY_REPEATER*
{curplan/edge0/TOPOLOGY_REPEATER0 curplan/edge0/TOPOLOGY_REPEATER1
curplan/edge0/TOPOLOGY_REPEATER2}
```

---

get_total_flop_count

Get total flop count for specific test_mode and model or for all models and RTL.

Syntax

int *get_total_flop_count*

```
[-CTL ]
[-model test model]
[-test_mode mode list]
```

Data Types

CTL	bool
model	string
test_mode	string

Feedback

Arguments

`-CTL`

Extract flop count only for CTL for a specific mode and model.

`-model` *`test model`*

Specifies the test model.

`-test_mode` *`mode list`*

Specifies the mode or mode list you want the number of chains from.

Description

This command calculates the flop count inside CTL, as well as the RTL depending upon the test mode and model arguments. We may get the flop count for specific test_mode and model or for default mode and RTL.

Examples

The following example returns only the CTL flop count for model sadsls0c4l2p2048x32m8b1w0c0p0d0r1s2z1rw00 for Internal_scan test mode.

```
prompt> get_total_flop_count -CTL -model
 sadsls0c4l2p2048x32m8b1w0c0p0d0r1s2z1rw00 -test_mode  Internal_scan
176
```

The following example returns the total flop count for CTL and RTL combined.

```
prompt> get_total_flop_count
2867
```

- get_cells

---

get_trace_option

Get the current option value controlling behavior of command tracing and output annotation..

Syntax

get_trace_option [-command name |-profile |-memory_threshold |-cpu_threshold |-time_treshold] [-annotate | -is_traced]

string *name*

Feedback

Arguments

`-command` *name*

This option is mutually exclusive with -profile, -memory_threshold, -cpu_threshold, and -time_threshold. The option identifies the command for which tracing or annotation option is returned.

`-annotate`

If this option is given, then the *annotate* setting for the given command is returned. This option is mutually exclusive with -is_traced and is meaningful only in combination with the -command option.

`-is_traced`

If this option is given, then returns 1 if the given command is traced and logged, 0 otherwise. This option is mutually exclusive with -annotate and is meaningful only in combination with the -command option.

`-profile`

This option is mutually exclusive with all others. The option returns a list of the currently enabled profile metrics, or "all" if all metrics are enabled.

`-memory_threshold`

This option is mutually exclusive with all others. The option returns the currently set memory profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

`-cpu_threshold`

This option is mutually exclusive with all others. The option returns the currently set cpu profile threshold, if any, in seconds. If no threshold is set, then it returns the string "unset".

`-time_threshold`

This option is mutually exclusive with all others. The option returns the currently set wall clock time profile threshold, if any, in kilobytes. If no threshold is set, then it returns the string "unset".

Description

The command is used to query the current setting for the command annotation option that is set with the set_trace_option command, or profile metric settings.

Examples

The following example sets the annoation type of the *get_attribute* command.

```
prompt> get_trace_option -command get_attribute -annotate
annotate
```

Feedback

The following example sets, then gets, the currently enabled profile metrics.

```
prompt> set_trace_topion -profile {cpu time}
prompt> get_trace_topion -profile
cpu time
```

The following example gets the threshold for memory profile metric before one has been set.

```
prompt> get_trace_option -memory_threshold
unset
```

The following example will list the commands in the Builtins command group that are not traced and logged.

```
prompt> foreach cmd [dict get [get_defined_commands -details -groups
 Builtins] commands] {
?  if {![get_trace_option -command $cmd -is_traced]}
?    {echo $cmd}
?  }
```

- set_trace_option

---

get_tracks

Creates a collection of tracks from the current design.

Syntax

```
collection get_tracks
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within region
```

Feedback

```
  | -touching region
  | -intersect region]
```

Data Types

```
design          collection
expression      string
exact_count     integer
minimum_count   integer
patterns        string
objects         list
point           list
region          list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on bound attributes. You can determine the shape attributes by using the *list_attributes* command. If the expression evaluates to *true*, the shape is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for tracks level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-of_objects` *`of_objects`*

Creates a collection of tracks that are located on the specified layers or in the specified edit groups. Each object in the list can be a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches the track names in the current design against the specified patterns. You can specify the patterns by using the following formats:

- A collection of tracks
- An asterisk (*), which indicates all tracks
- Track names, which are in the format TRACK_*object_id*

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all tracks at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be

Feedback

specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all tracks that are completely inside the specified region and doesn't include tracks which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all tracks that are completely inside the specified region and the tracks which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Feedback

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all tracks which are abut/touching from inside or outside to the specified region and the tracks whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command returns a collection of tracks of the current design that meet the selection criteria. You can use this command to query the tracks inside the database by layer, by point, or by region. You can also use this command to query tracks by filtering their attributes.

Examples

The following example returns the tracks that are located on the METAL2 layer.

```
prompt> get_tracks * -filter "layer~=METAL2"
{"TRACK_4683"}
```

The following example returns all tracks.

```
prompt> get_tracks "TRACK_*"
{"TRACK_4683 TRACK_5389"}
```

The following examples shows how to use the *get_attribute* command to query the value of a track attribute.

```
prompt> get_attribute [get_tracks  TRACK_43] layer_name
METAL2
```

Feedback

```
prompt> get_attribute [get_tracks  TRACK_43] layer
{"METAL"}

prompt> get_attribute [get_tracks TRACK_43] bbox
{{0.000 0.000} {100.000 100.000}}

prompt> get_attribute [get_tracks TRACK_43] start
0.000 0.000

To get a complete report of the attribute values of all tracks,
use the report_attributes command.
```

- report_attributes

---

get_undo_info

Returns information about the undo history and the undo system.

Syntax

```
array get_undo_info
[-name marker_name | -current | -system | -user | -all |
 -command command_name]
[-details]
```

Data Types

```
marker_name       string
command_name      string
```

Arguments

`-name marker_name`

Return information about the undo marker with the specified user or system name.

`-current`

Return information about the current undo marker. If the system is at its most recent state, then no marker is the current marker and an empty string will be returned.

`-system`

Return a list of all system-generated markers in the undo history.

Feedback

`-user`

Return a list of all user-generated markers in the undo history.

`-all`

Return a list of all markers in the undo history.

`-command` *`command_name`*

Return information about the undoability of the specified command.

`-details`

When used with the *-all*, *-user*, or *-system*, include detailed information about each marker in the returned marker list.

Description

This command returns information about the undo system, the undo history, and the undoability of commands. If the *-name* or *-current* option is used, an array of information about the specified marker is returned. The *-name* option specifies the marker with user or system name *marker_name*. The *-current* option specifies the marker corresponding to the current point in undo history, being the point before the command represented by the marker in the case of system markers. If system is at its most recent state, then no marker is the current marker, and an empty string will be returned.

If the *-all*, *-user*, or *-system* option is used, then a list of names of all, user-generated, or system-generated markers will be returned, respectively. If the *-details* option is also used, then a list of arrays of complete information about the specified markers is returned.

The following attribute/value pairs are included in marker information arrays (note: user markers are created with the *create_undo_marker* command; system markers are automatically created whenever an undoable command is executed):

```
marker            System name - always non-empty
name              User name - non-empty for user markers
command_name      Name of the command this marker corresponds to -
 non-empty
                           for system markers
memory            Memory used by the marker to store data required to
 transition
                           system state to or from the next more recent
 marker or the latest
                           state if there are no more recent markers.
current           True if this is the current marker, false otherwise.
```

If the *-command* option is used, this command returns 0, 1, or 2 if the command is not undoable, undoable, or unknown to the undo system, respectively.

If no options are specified, then this command returns an array of information about the undo system.

Feedback

Examples

The following gets a detailed list of all undo markers:

```
prompt> get_undo_info -all -details
{marker "SNPS_MARKER_131923" name "my_marker" command_name "" memory 0
 current false}
{marker "SNPS_MARKER_131924" name "" command_name "create_edit_group"
 memory 19932 current false}
{marker "SNPS_MARKER_131925" name "" command_name "add_to_edit_group"
 memory 20416 current false}
```

The following gets a list of all system markers:

```
prompt> get_undo_info -system
"SNPS_MARKER_131924" "SNPS_MARKER_131925"
```

The following gets a list of all user markers:

```
prompt> get_undo_info -user
"my_marker"
```

The following gets the undoability of the *place_and_optimize_design* command:

```
prompt> get_undo_info -command place_and_optimize_design
Information: The command 'place_and_optimize_design' is not undoable.
 (UNDO-015)
0
```

get_unix_variable

This is a synonym for the *getenv* command.

See Also

- printenv
- printvar
- setenv
- sh

Feedback

get_upf_design_attribute

Returns the value of a UPF attribute set on the specified objects.

Syntax

string *get_upf_design_attribute*

```
-objects object_list
-attribute attribute_name
```

Data Types

```
object_list           list
attribute_name        string
```

Arguments

`-objects object_list`

Specifies a list of objects from which to get the UPF attribute values.

`-attribute attribute_name`

Specifies the name of the attribute whose value is returned.

Supported values are: UPF_terminal_boundary, UPF_is_hard_macro, UPF_is_soft_macro, UPF_enable_bias.

Description

The *get_upf_design_attribute* command is used to query cell instances for the value of attributes that can be set on them through UPF commands (for example, set_design_attributes) or derived from their library model.

Examples

The following example queries if the hierarchical cell 'mid1' is marked as a UPF soft macro.

```
prompt> get_upf_design_attribute -objects [get_cells mid1] -attribute
 UPF_is_soft_macro
false
```

See Also

- set_design_attributes

get_upf_port_attribute

Returns the value of a UPF attribute set on the specified objects.

Feedback

Syntax

string *get_upf_port_attribute*

```
-objects object_list
-attribute attribute_name
```

Data Types

```
object_list           list
attribute_name        string
```

Arguments

`-objects object_list`

Specifies a list of objects from which to get the UPF attribute values.

`-attribute attribute_name`

Specifies the name of the attribute whose value is returned.

Supported values are: UPF_driver_supply, UPF_receiver_supply, UPF_feedthrough, UPF_unconnected, UPF_clamp_value, UPF_async_clamp_value, UPF_is_analog, UPF_literal_supply, UPF_related_supply_set, iso_source, iso_sink, resolved_iso_strategy, repeater_supply, repeater_power_net, and repeater_ground_net.

Description

This command is used to query pins and ports for the value of attributes that can be set on them through UPF commands (for example, set_port_attributes) or derived from their library model.

Examples

The following example gets the value of the *UPF_receiver_supply* attribute for the top_out port.

```
prompt> get_upf_port_attribute -objects [get_ports top_out] -attribute
 UPF_receiver_supply
AO_SS
```

See Also

- set_port_attributes

---

get_user_units

This command returns a string representing the input or output unit for one quantity type.

Feedback

Syntax

string *get_user_units*

```
-input | -output
-type unit_type
[-numeric]

string unit_type
```

Arguments

`-input`

Get the unit for data input. Either *-input* or *-output* must be specified.

`-output`

Get the unit for data output. Either *-input* or *-output* must be specified.

`-type unit_type`

Specifies the type of quantity, which must be one of "time", "resistance", "capacitance", "voltage", "power" or "current".

`-numeric`

If specified, return the value as a number representing the unit value in terms of the base unit for that quantity type. Base units are seconds, Ohms, Farads, Volts, and Amperes.

Description

This command returns a string representing the input unit for one quantity type. The tool maintains separate units for input and input. There are input unit values for time, resistance, capacitance, power, voltage and current.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example shows how to get the input unit for time. With the *-numeric* option, the value is returned in terms of the base unit for that quantity type (seconds, for time).

```
prompt> get_user_units -input -type time
1.00ps
prompt> get_user_units -input -type time -numeric
1e-12
```

Feedback

See Also

- report_user_units
- set_user_units

---

get_utilization_configurations

Creates a collection of utilization configurations from the scopes lib, tech and block.

Syntax

```
collection get_utilization_configurations
[-block block]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-scope scope]
[patterns]
```

Data Types

```
expression      string
patterns        list
scope           string
```

Description

This command creates and returns a collection of all the existing utilization configurations.

Arguments

`-block block`

Specifies the block in which the configurations are to be found.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the utilization-configuration attributes. You can determine the utilization-configuration attributes by using the *list_attributes* command. If the expression evaluates to *true*, the specific configuration is included in the collection. By default, this option is off.

Feedback

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-scope` *`scope`*

The values it can take are 'lib', 'tech' and 'block'. By default, the order of search is block, lib and then tech i.e. the configuration is first searched in the current block, then the current library and finally the tech associated with the current library.

`patterns`

Matches the configuration names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

Feedback

Examples

The following example lists the configurations created through the *create_utilization_configuration* command.

```
prompt> create_utilization_configuration config_lib -capacity core_area
 -scope lib
prompt> create_utilization_configuration config_tech -capacity boundary
 -scope tech
prompt> create_utilization_configuration config_block -capacity
 site_array -scope block

prompt> get_utilization_configurations
{config_lib config_tech config_block}
prompt> get_utilization_configurations -scope lib
{config_lib}
prompt> get_utilization_configurations -scope tech
{config_tech}
prompt> get_utilization_configurations -scope block
{config_block}
```

See Also

- create_utilization_configuration
- remove_utilization_configurations
- report_utilization

---

get_via_defs

Creates a collection by selecting via_defs from a block or tech.

Syntax

```
collection get_via_defs
[-design design]
[-library library]
[-tech tech]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
patterns | -of_objects of_objects
```

Feedback

Data Types

design	collection
library	collection
tech	string
expression	string
exact_count	int
minimum_count	int
patterns	string
of_objects	list

Arguments

`-design` *design*

Specifies the block for finding via_defs. If neither a design nor tech is specified, the current block is used.

`-library` *library*

Specifies the tech for finding via_defs. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used.

`-tech` *tech*

Specifies the tech for finding via_defs. If neither a design nor tech is specified, the current block is used.

`-filter` *expression*

Filters the collection with *expression*. For any via_def that matches the patterns option, the expression is evaluated based on the via_def's attributes. If the expression evaluates to *true*, the via_def is included in the result. By default, this option is off.

Use the *list_attributes* command to determine the via_def attributes.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive. *-nocase* and *-exact* are mutually exclusive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection containing the via_defs of the specified vias. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches the via_def names against the patterns in the specified block or tech.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Description

This command creates a collection of via_defs by selecting via_defs from the specified block or tech that meet the selection criteria. It returns a collection handle if one or more via_defs meet the selection criteria. If no via_defs match the selection criteria, it returns an empty string.

Use the *get_via_defs* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Feedback

Examples

The following example creates the collection of all custom via_defs used in the current block:

```
prompt> get_via_defs -of_objects VIA_C*
{FATVIA12_230_530 FATVIA12_530_230}
```

The following example creates the collection of all via_defs from the tech of library 'test' with cut layer VIA1 :

```
prompt> get_via_defs -tech [get_techs -of_objects test] -filter
 "cut_layer_name == VIA1"
{VIA12 FATVIA12}
```

See Also

- get_attribute
- query_objects
- report_via_defs

---

get_via_ladders

Creates a collection by selecting via ladder from the design.

Syntax

```
collection get_via_ladders
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects]
```

Data Types

```
design            collection
expression        string
exact_count       int
minimum_count     int
patterns          string
objects           list
```

Feedback

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any via ladder that match the patterns option, the expression is evaluated based on the attributes of the via ladder. If the expression evaluates to *true*, the via ladder is included in the result. By default, this option is off.

Use the *list_attributes* command to determine the via ladder attributes.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

Feedback

`-hierarchical`

Searches for vias level-by-level relative to the current instance. This option is useful only with *patterns* and not with *-of_objects*.

`-of_objects` *`of_objects`*

Creates a collection containing the via ladders connected to the specified net. Each object in the list is a name, pattern, or collection.

The *patterns* and *-of_objects* arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches the via ladder names against the patterns in the current design. You can specify the patterns with the following formats:

- * (asterisk) indicates all via ladders

The *patterns* and *-of_objects* arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Description

This command creates a collection of via ladders by selecting via ladders from the current design that meet the selection criteria. It returns a collection handle if one or more via ladders meet the selection criteria. If no via ladders match the selection criteria, it returns an empty string.

Use the *get_via_ladders* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following example create via ladder collections of net MemData[31]:

```
prompt> get_via_ladders -of_objects MemData[31]
{VIA_LADDER_0}
```

The following example gets all via ladders using '*' :

```
prompt> get_via_ladders *
{VIA_LADDER_0 VIA_LADDER_1}
```

The following example gets via ladders using regular expression match :

```
prompt> get_via_ladders -regexp VIA_LADDER_.
{VIA_LADDER_0 VIA_LADDER_1}
```

Feedback

---

get_via_matrixes

Creates a collection by selecting via matrixes from the design.

Syntax

```
collection get_via_matrixes
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects]
  | -at point
  | -within region
  | -touching region
  | -intersect region ]
```

Data Types

design	collection
expression	string
exact_count	int
minimum_count	int
patterns	string
objects	list
point	list
region	list

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter expression`

Filters the collection with *expression*. For any via matrix that match the patterns option, the expression is evaluated based on the via matrix's attributes. If the

Feedback

expression evaluates to *true*, the via matrix is included in the result. By default, this option is off.

Use the *list_attributes* command to determine the via matrix attributes.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for vias level-by-level relative to the current instance. This option is useful only with *patterns* and not with *-of_objects*.

`-of_objects` *`of_objects`*

Creates a collection containing the via matrixes connected to the specified net, or edit groups. Each object in the list is a name, pattern, or collection.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via matrix names against the patterns in the current design. You can specify the patterns with the following formats:

- * (asterisk) indicates all via matrixes

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all via_matrices at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the *-hierarchical* option with the *-at* option.

-within *region*

Creates a collection that contains all via_matrices that are completely inside the specified region and do not overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

Feedback

In addition, you cannot use the *-hierarchical* option with the *-within* option.

`-touching` *region*

Creates a collection that contains all via_matrices that are inside the specified region, including those that overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the *-hierarchical* option with the *-touching* option.

`-intersect` *region*

Creates a collection that contains all via_matrices that intersect the boundary of the specified region and at least part of the via_matrix is outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} or {*llx lly urx ury*}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the *-hierarchical* option with the *-intersect* option.

Feedback

Description

This command creates a collection of via matrixes by selecting via matrixes from the current design that meet the selection criteria. It returns a collection handle if one or more via matrixes meet the selection criteria. If no via matrixes match the selection criteria, it returns an empty string.

Use the *get_via_matrixes* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following examples create via matrix collections of net MemData[31]:

```
prompt> get_via_matrixes -of_objects MemData[31]
{VIA_MATRIX_0}
```

The following examples get all via matrixes for the same via definition VIA12 :

```
prompt> get_via_matrixes -filter "via_def_name==VIA12"
{VIA_MATRIX_0 VIA_MATRIX_1}
```

---

get_via_regions

Creates a collection of via regions in the frame block that match the specified criteria.

Syntax

```
collection get_via_regions
[-design block]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
patterns
  | -of_objects of_objects
  | -at point
  | -within region
```

Feedback

```
  | -touching region
  | -intersect region ]
```

Data Types

```
block          collection
expression     string
exact_count    int
minimum_count  int
patterns       string
of_objects     list
region         list
point          list
```

Arguments

`-design` *block*

Specifies the block for finding via_regions. If no design is specified, the current block is used.

`-filter` *expression*

Filters the collection with *expression*. For any via_regions that match the patterns option, the expression is evaluated based on the attributes for the via_region. If the expression evaluates to *true*, the via_region is included in the result. By default, this option is off.

Use the *list_attributes* command to determine the via_region attributes.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as a real regular expression rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matching case-insensitive. *-nocase* and *-exact* are mutually exclusive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

Feedback

`-expect` *exact_count*

Specifies the expected number of objects to find. If the command finds a different number of objects, a Tcl error is raised and command processing terminates.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error is raised and command processing terminates.

`-expect_each_pattern_matches`

Forces each pattern in *patterns* to match at least one object. If one or more patterns does not match, a Tcl error is raised and command processing terminates.

`-of_objects` *of_objects*

Creates a collection containing the via_regions of the specified terminals. Each object in the list is a name, pattern, or collection.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via_region names against the patterns in the specified block.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *point*

Creates a collection that contains all via_regions at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-within` *region*

Creates a collection that contains all via_regions that are completely inside the specified region and doesn't include via_regions which are abut/touching

Feedback

from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

`-touching` *region*

Creates a collection that contains all via_regions that are completely inside the specified region and the via_regions which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-intersect` *region*

Creates a collection that contains all via_regions which are abut/touching from inside or outside to the specified region and the via_regions whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

Description

This command creates a collection of via_regions by selecting via_regions from the specified block that meet the selection criteria. It returns a collection handle if one or more via_regions meet the selection criteria. If no via_regions match the selection criteria, it returns an empty string.

Use the *get_via_regions* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following example creates the collection of all via_regions of terminal Reset in current block:

```
prompt> get_via_regions -of_objects Reset
{Reset/VR_0 Reset/VR_1}
```

The following example creates the collection of all system via_regions in current block:

```
prompt> get_via_regions * -filter "type == SYSTEM"
{D1/VR_0  D1/VR_1}
```

- report_via_regions

---

get_via_rules

Returns a collection by selecting via_rules from a block and tech.

Feedback

Syntax

```
collection get_via_rules
[-design design]
[-library library]
[-tech tech_object]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns | -of_objects of_objects]
```

Data Types

```
design          collection
library         collection
tech_object     collection
expression      string
exact_count     integer
minimum_count   integer
patterns        string
of_objects      list
```

Arguments

`-design design`

Specifies the block for finding via_rules. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

`-library library`

Specifies the tech for finding via_rules. The tech contained by or referenced by the given library is used. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

`-tech tech_object`

Specifies the tech for finding via_rules. If neither a design nor tech is specified, the current block is used. If current block is not set then current lib is used.

`-filter expression`

Filters the collection with *expression*. For any via rule that match the patterns option, the expression is evaluated based on the via rule's attributes. If the expression evaluates to *true*, the via rule is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection containing the via rules of the specified techs. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches via rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Feedback

Description

The *get_via_rules* command creates a collection of via rules from the specified block scope and the tech scope that match certain criteria. The command returns a collection of via rules if any via rule matches the criteria. If no objects match the criteria, the empty string is returned. By default, the command returns the via rules in both block and tech scope. If the search is to be limited to either block or tech scope, the same can be specified as an option.

You can use the *get_via_rules* command at the command prompt, or you can nest it as an argument to another command, such as *report_attributes*. In addition, you can assign the *get_via_rules* result to a variable.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example returns a collection that contains all the via rules in the block and tech scope of the current block.

```
prompt> get_via_rules
{VR1 VL1 VL1}
```

See Also

- collections
- query_objects

---

get_vias

Creates a collection by selecting vias from the design.

Syntax

```
collection get_vias
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[-include_shield]
```

Feedback

```
[-shield_only]
[-include_lib_cell]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

design	collection
expression	string
exact_count	integer
minimum_count	integer
patterns	string
objects	list
point	list
region	list

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with *expression*. For any via that match the patterns option, the expression is evaluated based on the via's attributes. If the expression evaluates to *true*, the via is included in the result. By default, this option is off.

Use the *list_attributes* command to determine the via attributes.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

Feedback

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for vias level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-include_shield`

Specifies to include the shielding vias when -of_objects contains nets. It is only valid when -of_objects contains nets.

This option is mutually exclusive with -shield_only.

`-shield_only`

Specifies to get the shielding vias only when -of_objects contains nets. It is only valid when -of_objects contains nets.

This option is mutually exclusive with -include_shield.

`-include_lib_cell`

Search for vias in the *lib_cell*. By default, *lib_cell* vias are excluded from search.

This option must be used with -hierarchical option.

`-of_objects` *`of_objects`*

Creates a collection containing the vias connected to the specified net, port, terminal, lib_pin, or edit groups. Each object in the list is a name, pattern, or collection.

When ports are specified by *-of_objects*, *get_vias* searches for vias attached to the terminals associated with the specified ports.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the via names against the patterns in the current design. You can specify the patterns with the following formats:

- `* (asterisk) indicates all vias`
- *VIA** `indicates all vias`
- *VIA_S** `indicates all simple vias`
- *VIA_C** `indicates all custom vias`
- *VIA_C_120* `indicates one simple via.`

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *point*

Creates a collection that contains all vias at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *region*

Creates a collection that contains all vias that are completely inside the specified region and doesn't include vias which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *`region`*

Creates a collection that contains all vias that are completely inside the specified region and the vias which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *`region`*

Creates a collection that contains all vias which are abut/touching from inside or outside to the specified region and the vias whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

Feedback

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of vias by selecting vias from the current design that meet the selection criteria. It returns a collection handle if one or more vias meet the selection criteria. If no vias match the selection criteria, it returns an empty string.

Use the *get_vias* command as an argument to another command or assign its result to a variable. Refer to the example below for more information.

See the collection command man page for information about working with collections.

Examples

The following examples create via collections of net n300:

```
prompt> get_vias -of_objects n300
{"VIA_C_67"}
```

The following examples get all vias from the same via definition VIA12 :

```
prompt> get_vias -filter "via_def_name==VIA12"
{"VIA_S_120", "VIA_S_122", "VIA_S_123"}
```

See Also

- get_attribute

---

get_view_switch_list

Returns the value of the specified design, library, or global view switch list.

Feedback

Syntax

```
string get_view_switch_list
[-design design | -library library | -global]
[-explicit]
```

Data Types

```
design   string
library  string
```

Arguments

`-design design`

Specifies the design for which to return the view switch list. This option is mutually exclusive with the *-library* and *-global* options.

`-library library`

Specifies the library for which to return the view switch list. This option is mutually exclusive with the *-design* and *-global* options.

`-global`

Returns the global, session-wide view switch list. This option is mutually exclusive with the *-design* and *-library* options.

`-explicit`

Returns the view switch list that was explicit set on the specified entity. If this option is not specified, the command returns the effective view switch list that is applied to the entity in the case where no view switch list was explicitly set.

Description

This command returns the effective view switch list of a design, library, or global session.

The view switch list is a precedence-ordered list of design views that is applied when attempting to bind a design. If you explicitly set the switch list for the design, then that view switch list is used. If not explicitly set, the command returns the view switch list for the design's owning library. If the owning library does not have a view switch list that was explicitly set, then the global view switch list is used. The view switch list attribute is persistent for designs and libraries, but not for the global session.

It is an error to specify more than one of the *-global*, *-library*, or *-design* options. If none of these options are specified, the command returns the global view switch list. An empty view switch list is displayed as "{ }". If you specified the *-explicit* option and the command returns an empty view switch list, then no explicitly set view switch list exists on the entity. If you omitted the *-explicit* option and the command returns an empty view switch list, then the view switch list is empty for this entity and its owners. If the entity is a design in this case, then it cannot be bound.

Feedback

Examples

The following example gets the effective view switch list of design "mydesign":

```
prompt> get_view_switch_list -design mydesign
abstract outline
```

The following example gets the effective view switch list of library "mylib":

```
prompt> get_view_switch_list -library mylib
frame abstract design
```

The following examples each get the global view switch list:

```
prompt> get_view_switch_list
design frame abstract outline

prompt> get_view_switch_list -global

---

get_virtual_connections

Gets a list of virtual connection that match the specified input criteria.

Syntax

status *get_virtual_connections*

```
patterns
   | -of_objects objects
```

Data Types

patterns	list
objects	list

Arguments

patterns

Matches virtual connection names against patterns. Patterns can include the wildcard characters "*" and "?". Patterns can also include collections of type virtual connection.

Feedback

`-of_objects` *objects*

The command returns a list of virtual connection connected to the specified objects. Each object can be a pin, port and cell.

Description

This command gets a list of virtual connection that match the specified input criteria.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples get the virtual connection.

```
prompt> get_virtual_connections SNPS_VC_1

prompt> get_virtual_connections {SNPS_VC_1 SNPS_VC_2}

prompt> get_virtual_connections VC*

prompt> get_virtual_connections \\
        -of_objects [get_pins {U212/ZN U256/I}]

prompt> get_virtual_connections \\
        -of_objects [get_cells {U300 U391}]

prompt> get_virtual_connections \\
        -of_objects [get_ports WriteAdd[0]]

prompt> get_virtual_connections \\
        -of_objects {U300/ZN U212 MemData[0]}
```

See Also

- add_pins_to_virtual_connection
- create_virtual_connection
- get_attribute
- place_eco_cells
- remove_pins_from_virtual_connection
- remove_virtual_connections
- set_attribute

Feedback

get_voltage_area_rules

Returns a collection of voltage_area_rules from the design.

Syntax

collection *get_voltage_area_rules*

```
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[patterns]
```

Data Types

```
design          collection
expression      string
exact_count     int
minimum_count   int
patterns        string
```

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter expression`

Filters the collection with the value of *expression*, which must be a boolean expression based on the voltage_area_rule attributes. You can determine the voltage_area_rule attributes by using the *list_attributes* command. If the expression evaluates to *true*, the voltage_area_rule is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

Feedback

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. Wildcards are considered as plain characters. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options.

`patterns`

Matches voltage_area_rule names against *patterns*. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

Description

This command creates a collection of voltage_area_rules from the design. The command returns a collection handle (identifier) if any voltage_area_rules match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the *get_voltage_area_rules* command at the command prompt or nest it as an argument to another command (such as *report_voltage_area_rules*). You can also assign the *get_voltage_area_rules* result to a variable.

See the *collections* command man page for information about working with collections.

Feedback

Examples

The following example returns a collection of voltage_area_rules with names starting with "RULE".

```
prompt> get_voltage_area_rules RULE*
```

The following example returns a collection of voltage_area_rules which allow physical feedthrough.

```
prompt> get_voltage_area_rules -filter is_physical_feedthrough_allowed
```

See Also

- create_voltage_area_rule
- remove_voltage_area_rules
- report_voltage_area_rules

---

get_voltage_area_shapes

Creates a collection of voltage_area shapes from the current design.

Syntax

```
collection get_voltage_area_shapes
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design          string
expression      string
exact_count     integer
minimum_count   integer
patterns        list
objects         list
```

Feedback

```
point           list
region          list
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter` *expression*

Filters the collection with the value of *expression*, which must be a Boolean expression based on the voltage_area shapes attributes. You can determine the voltage_area shapes attributes by using the *list_attributes* command. If the expression evaluates to *true*, the voltage area shapes are included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

Feedback

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for voltage area shapes level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-of_objects` *`objects`*

Creates a collection containing the voltage_area shapes of the specified voltage_areas, power_domains, cells, or edit groups. Each object in the list is a name, pattern, or collection.

The *patterns* argument and *-of_objects* option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the *pattern*.

`patterns`

Matches the voltage_area shape names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

`-at` *`point`*

Creates a collection that contains all voltage area shapes at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-within` *`region`*

Creates a collection that contains all voltage area shapes that are completely inside the specified region and doesn't include voltage area shapes which are

Feedback

abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all voltage area shapes that are completely inside the specified region and the voltage area shapes which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all voltage area shapes which are abut/touching from inside or outside to the specified region and the voltage area

Feedback

shapes whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of voltage_area shapes from the current design that match certain criteria. The command returns a collection handle (identifier) if any voltage_area shapes match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the *get_voltage_area_shapes* command at the command prompt or nest it as an argument to another command (such as *remove_voltage_area_shapes*). You can also assign the *get_voltage_area_shapes* result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following returns voltage_area shapes of a voltage_area

```
prompt> get_voltage_area_shapes -of_objects [get_voltage_area VA_1]
{VA1}
```

See Also

- create_voltage_area

Feedback

- remove_voltage_areas
- report_voltage_areas

---

get_voltage_areas

Creates a collection of voltage_areas from the current design.

Syntax

```
collection get_voltage_areas
[-design design]
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-hierarchical]
[patterns
  | -of_objects objects
  | -at point
  | -within region
  | -touching region
  | -intersect region]
```

Data Types

```
design          string
expression      string
exact_count     integer
minimum_count   integer
patterns        list
objects         list
point           list
region          list
```

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-filter expression`

Filters the collection with the value of *expression*, which must be a Boolean expression based on the voltage_area attributes. You can determine the voltage_area attributes by using the *list_attributes* command. If the expression

Feedback

evaluates to *true*, the voltage_area is included in the collection. By default, this option is off.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-hierarchical`

Searches for voltage areas level-by-level relative to the current instance. This option is useful with *patterns*, *-within*,*-touching*, *-intersect* and *-at*, but not with *-of_objects*.

`-of_objects` *`objects`*

Creates a collection containing the voltage_areas associated with the specified objects. The objects can be voltage_area shapes, power domains, supply nets, cells, or edit groups. Each object in the list is a name, pattern, or collection.

Feedback

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

patterns

Matches the voltage_area names against the patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

-at *point*

Creates a collection that contains all voltage_areas at the specified point. The format for specifying a point is {*x y*}.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

-within *region*

Creates a collection that contains all voltage_areas that are completely inside the specified region and doesn't include voltage_areas which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be

Feedback

specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-touching` *region*

Creates a collection that contains all voltage_areas that are completely inside the specified region and the voltage_areas which are abut/touching from inside with the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

`-intersect` *region*

Creates a collection that contains all voltage_areas which are abut/touching from inside or outside to the specified region and the voltage_areas whose part of it is outside the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{*llx lly*} {*urx ury*}} , which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{*x1 y1*} {*x2 y2*} ... {*xN yN*} {*x1 y1*}}, where each {*x y*} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, *-of_objects*, *-within*, *-touching*, *-intersect*, and *-at* arguments are mutually exclusive; you can specify only one except *-within* and *-intersect* can be

Feedback

specified together. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

By default, query will be limited to current physical hierarchy. *-hierarchical* can be specified to query objects across physical hierarchies.

Description

This command creates a collection of voltage_areas from the current design that match certain criteria. The command returns a collection handle (identifier) if any voltage_areas match the value of the *patterns* option and pass the filter (if specified). If no objects match the criteria, the command returns an empty string.

You can use the *get_voltage_areas* command at the command prompt or nest it as an argument to another command (such as *report_voltage_areas*). You can also assign the *get_voltage_areas* result to a variable.

See the *collections* command man page for information about working with collections.

Examples

The following returns voltage_area from its shapes

```
prompt> get_voltage_areas -of_objects [get_voltage_area_shapes
 VOLTAGE_AREA_SHAPE_1]
{VA_1}
```

See Also

- create_voltage_area

- remove_voltage_areas
- report_voltage_areas

---

get_vsdc

Get the name of the current VSDC file.

Syntax

```
boolean get_vsdc
```

Feedback

Description

This command prints the name of the VSDC file that is currently open for recording VSDC guidance for Formality. If no VSDC file has been specified using the *set_vsdc* command, a message is printed.

Examples

In this example, we query the name of the VSDC file and find out that setup information is not being recorded yet. Then we specify the file name and repeat the query.

```
prompt> get_vsdc
VSDC guidance is not enabled.
1
prompt> set_vsdc cache_ctrl.vsdc
1
prompt> get_vsdc
The current VSDC file is /project/chip/cache_ctrl/cache_ctrl.vsdc.
1
```

See Also

- set_vsdc
- set_svf

---

get_waiver_containers

Creates a collection of DRC error waiver container objects.

Syntax

```
collection get_waiver_containers
[-filter expression]
[-quiet]
[-regexp]
[-nocase]
[-exact]
[-expect exact_count]
[-expect_at_least minimum_count]
[-expect_each_pattern_matches]
[-of_objects of_objects]
[patterns]
```

Data Types

```
expression        string
exact_count       int
minimum_count     int
of_objects        list
patterns          list
```

Feedback

Arguments

`-filter` *`expression`*

Filters the collection with *expression*.

For any DRC error waiver container objects that match the *patterns* or *objects* argument, the expression is evaluated based on the DRC error waiver container object's attributes. If the expression evaluates to true, the DRC error waiver container object is included in the result.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-regexp`

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. *-regexp* and *-exact* are mutually exclusive.

`-nocase`

Makes matches case-insensitive.

`-exact`

Disables simple pattern matching. For use when searching for objects that contain the * and ? wildcard characters. *-exact* and *-regexp* are mutually exclusive.

`-expect` *`exact_count`*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

`-expect_at_least` *`minimum_count`*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

`-expect_each_pattern_matches`

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

`-of_objects` *`of_objects`*

Creates a collection of physical DRC errors connected to the specified objects.

Feedback

patterns

Matches physical DRC error waiver container names against patterns. Patterns can include the wildcard characters "*" and "?" or regular expressions, based on the *-regexp* option. Patterns can also include collections of drc error waiver objects.

Description

The *get_waiver_containers* command creates a collection of DRC error waiver containers in the given error data that match certain criteria. The command returns a collection if any waiver containers match the *patterns* or *objects* and pass the filter (if specified). If no objects match the criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl *regexp* command. When using *-regexp*, take care in the way you quote the *patterns* and filter *expression*; use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the *get_waiver_containers* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *get_waiver_containers* result to a variable.

When issued from the command prompt, *get_waiver_containers* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum by setting the *shell.commmon.collection_result_display_limit* application option.

The "implicit query" property of *get_waiver_containers* provides a fast, simple way to display DRC error waiver containers in a collection. However, if you want the flexibility provided by the *query_objects* options (for example, if you want to display the object class), use *get_waiver_containers* as an argument to *query_objects*.

For information about collections and the querying of objects, see the *collections* man page.

Examples

The following example queries the DRC error waiver container that is named con1.

```
prompt> get_waiver_containers con1
{con1}
```

The following example shows that, given a collection of DRC error waivers, you can query the DRC error waiver containers connected to those waivers.

```
prompt> set waver [get_drc_error_waivers w1]
{w1}
```

Feedback

```
prompt> query_objects [get_waiver_containers -of_objects $waver]
{con1}
```

The following example gets the DRC error waivers associated with an waiver container.

```
prompt> get_drc_error_waivers -of_objects [get_waiver_containers con1]
{w1, w2}
1
```

---

get_working_design_stack

Gets the current working design stack.

Syntax

```
collection get_working_design_stack
[-instance]
```

Arguments

`-instance`

When specified the command returns pushed instance of current block within top hierarchy

Description

The command returns a collection that contains the current working design stack or the pushed instance of current block within top hierarchy

The first object of the returned collection is the top-level design, the second is the child design of the top-level design, and so on. The last element of the returned collection is the current working design, which you can get by using the *current_design* command.

Examples

The following example uses the *get_working_design_stack* command to return the working design stack before and after running the *set_working_design* command.

Feedback

```
prompt> get_working_design_stack
{ORCA}
prompt> set_working_design -push I_ORCA_TOP/I_BLENDER_4
1
prompt> get_working_design_stack
{ORCA BLENDER_2}
prompt> get_working_design_stack -instance
{I_ORCA_TOP/ORCA BLENDER_2}
```

See Also

- current_design
- set_working_design
- set_working_design_stack

---

get_working_ml_db_record

Returns the full name of the working hierarchical record.

Syntax

string *get_working_ml_db_record*

Description

The *get_working_ml_db_record* command returns the working hierarchical record as a string if successful, or "0" if not, with a TCL error raised.

Examples

The following example uses *get_working_ml_db_record* to get the working hierarchical record.

```
prompt> get_working_ml_db_record
/R1/R4
```

See Also

- set_working_ml_db_record

---

getenv

Returns the value of a system environment variable.

Syntax

string *getenv*

Feedback

```
        variable_name
```

Data Types

```
variable_name      string
```

Arguments

variable_name

Specifies the name of the environment variable to be retrieved.

Description

The *getenv* command searches the system environment for the specified *variable_name* and sets the result of the command to the value of the environment variable. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the *env* Tcl array variable. The *getenv*, *setenv*, and *printenv* environment commands are convenience functions to interact with this array.

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you set the variable to a new value using the *setenv* command, you see the new value within the application and within any new child processes you initiate from the application using the *exec* command. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the *exec* command, that value is not reflected in the current application.

See the *set*, *unset*, and *printvar* commands for information about working with non-environment variables.

Examples

In the following example, *getenv* returns you to your home directory:

```
prompt> set home [getenv "HOME"]
/users/disk1/bill

prompt> cd $home

prompt> pwd
/users/disk1/bill
```

In the following example, *setenv* changes the value of an environment variable:

```
prompt> getenv PRINTER
laser1
```

Feedback

```
prompt> setenv PRINTER "laser3"
laser3

prompt> getenv PRINTER
laser3
```

In the following example, the requested environment variable is not defined. The error message shows that the Tcl variable *env* was indexed with the value UNDEFINED, which resulted in an error. In the second command, *catch* is used to suppress the message.

```
prompt> getenv "UNDEFINED"
Error: can't read "env(UNDEFINED)": no such element in array
        Use error_info for more info. (CMD-013)

prompt> if {[catch {getenv "UNDEFINED"} msg]} {
         setenv UNDEFINED 1
       }
```

group_cells

Creates a new level of hierarchy

Syntax

collection *group_cells*

```
[cell_list]
[-module_name module_name]
[-cell_name cell_name]
[-phys_wrapper]
[-hdl_block block_name]
[-hdl_all_blocks]
[-hdl_bussed]
[-enable_mim mim_module_name]
[-strict_mim]
[-follow_order]
```

Feedback

Data Types

cell_list	list
module_name	string
cell_name	string
block_name	string
mim_module_name	string

Arguments

cell_list

Specifies the list of cells that are grouped into a new level of hierarchy. All of the cells must be instances in the same module. To specify more than one cell is, enclose the list in ({}) brackets. The cell names cannot be specified with the following options: *-hdl_block*, *-hdl_all_blocks*, and *-hdl_bussed*.

-module_name *module_name*

Specifies the name to be given to the newly created module. The specified name is taken as a suggestion; if it is not available, the tool generates a module name automatically and prints a warning message.

If *module_name* is not specified or if the specified name is not available, the tool automatically generates a name of the form "group_0", "group_1", and so on.

-cell_name *cell_name*

Specifies the name to be given to the cell that instantiates the new hierarchy. The specified name is taken as a suggestion; if it is not available in the parent module, the tool generates a cell name automatically and prints a warning message.

If *cell_name* is not specified or if the specified name is not available, the tool automatically generates a name of the form "group_cell_0". Since a single counter is used for all tool generated cell names, the number in the suffix might not start at 0 and might not be sequential across multiple invocations of the command.

-phys_wrapper

Specifies that a single hierarchical cell is being grouped for use with design planning, possibly as a step toward creating a new physical hierarchy. If this option is specified, the new module's ports and nets have the same names as the corresponding ports and nets in the specified cell, rather than inheriting their names from the parent module's nets. Do not specify more than one cell or a nonhierarchical cell, when using this option.

As the wrapper cell inherits the port and net names from the inner cell, any constraints on those objects are not moved to the wrapper cell.

Feedback

`-hdl_block` *`block_name`*

Groups all cells of a HDL block created in the RTL file. The *-hdl_block* option requires that you specify HDL block label name in the current instance. Nested HDL block labels are separated by a /(slash)for example, my_process/my_function. The *block_name* must reference a single label name. Wildcards are supported for label names, but they do not match hierarchy characters. If wildcards match multiple labels, the first block with cells is used.

`-hdl_all_blocks`

Groups all HDL blocks into a level of hierarchy. If only *-hdl_all_blocks* option is used, it recursively groups all the HDL blocks in the current hierarchy. If you use this option with *-hdl_block* option, all HDL blocks from the *block_name* label are recursively grouped.

`-hdl_bussed`

Places each group of bus gates created from HDL into a level of hierarchy. If you use this option with *-hdl_block* option, blocks specified by the *block_name* are recursively grouped.

`-enable_mim` *`mim_module_name`*

Specifies the multiply instantiated modules module name for multi instance group cells. The tool verifies and tries to match the group cells with the target multiply instantiated modules module. It even tries to match them by making possible connection changes. If they are not compatible, the command errors out or continues with normal group cells based on the *-strict_mim* option.

`-strict_mim`

Directs the multiply instantiated modules group cells flow to error out or disable in case of an errors. If *-strict_mim* option value is set to present, the command errors out, else gives a warning and continues with the normal group cells.

`-follow_order`

Directs the multiply instantiated modules group cells flow to follow order of the provided group cells instances for instance mapping. If *-follow_order* is present, it stops the internal auto inferencing of instance mapping for the group cells, and follows the instance order provided with the *group_cells* command.

Description

This command groups any number of cells in the same parent module into a new module, and instantiates that module as a cell instance in the original parent module. The cells do not have to be in the current block or current instance, but all cells to be grouped have to be in the same parent module. A collection containing the newly-created cell is returned.

Feedback

The new module's port directions are determined automatically based on the driver and load pins connected both inside and outside the new hierarchy.

This command operates on a single instance of the parent module that contains the cells being grouped. If that module is multiply instantiated, a separate, unique module is created for this instance and the new hierarchy appears only in that instance's module.

For *-hdl_block*, *-hdl_all_blocks*, and *-hdl_bussed* options, only HDL blocks within the current instance can be referenced. To reference HDL blocks inside submodules, use the *current_instance* command to change the current instance to the parent block containing the HDL block. References to recursive grouping in the ARGUMENTS section refer to nested labels within the current instance, not to logical design hierarchy.

Examples

The following example groups two cells in parent cell "mid1" into a new module "BOT" with cell instance "bot1":

```
prompt> group_cells -module_name BOT -cell_name bot1 {mid1/U1 mid1/U2}
{bot1}
prompt> get_cells mid1/bot1/*
{mid1/bot1/U1 mid1/bot1/U2}
```

The following example groups all cells named "decoder_*" into a new module, allowing the tool to generate the new module and cell names:

```
prompt> group_cells [get_cells decoder_*]
{group_cell_4}
prompt> current_instance group_cell_4
group_cell_4
prompt> get_cells
{group_cell_4/decoder_1 group_cell_4/decoder_0}
```

The following example groups all cells in all the HDL blocks into separate level of hierarchy (or modules);

```
prompt> current_instance bot1
prompt> group_cells -hdl_all_blocks
{group_cell_0 group_cell_1 ...}
```

The following example groups all cells in the HDL function named bar and the process named proc into a module:

```
prompt> current_instance bot1
prompt> group_cells -hdl_block proc/bar
{group_cell_0}
```

Feedback

The following example groups all bus gates under the process named proc into separate level of hierarchy (or modules):

```
prompt> current_instance bot1
prompt> group_cells -hdl_block proc -hdl_bussed
{group_cell_0 group_cell_1 ...}
```

The following example shows usage of group_cells with MIM and strict_mim;,

```
prompt> current_instance bot1
prompt> group_cells -cell_name mm1 -enable_mim hier1 -strict_mim
{group_cell_0 group_cell_1 ...}
prompt> group_cells -cell_name mm1 -enable_mim hier1 -strict_mim
{group_cell_3 group_cell_4 ...}
```

The following example shows usage of group_cells with MIM and follow_order,

```
prompt> current_instance bot1
prompt> group_cells -cell_name mm1 -enable_mim hier1 -strict_mim
 -follow_order
{group_cell_0 group_cell_1 ...}
prompt> group_cells -cell_name mm1 -enable_mim hier1 -strict_mim
 -follow_order
{group_cell_3 group_cell_4 ...}
```

group_path

Groups paths for cost function calculations and reporting.

Syntax

status *group_path*

```
-name group_name
[-default]
[-weight weight_value]
[-critical_range range_value]
[-from from_list]
[-rise_from rise_from_list]
[-fall_from fall_from_list]
[-through through_list]
[-rise_through rise_through_list]
[-fall_through fall_through_list]
[-to to_list]
[-rise_to rise_to_list]
[-fall_to fall_to_list]
```

Feedback

```
[-priority priority_level]
[-comment comment]
```

Data Types

```
group_name          string
weight_value        float
range_value         float
from_list           list
rise_from_list      list
fall_from_list      list
through_list        list
rise_through_list   list
fall_through_list   list
to_list             list
rise_to_list        list
fall_to_list        list
priority_level      integer
comment             string
```

Arguments

`-name group_name`

Specifies a name for the path group.

If a group with this name already exists, the paths are added to that group. If a group with this name does not exist, a new group is created.

The *-name* and *-default* options are mutually exclusive; you must specify one of these options.

`-default`

Removes the specified endpoints or paths and moves them to the default group.

The *-name* and *-default* options are mutually exclusive; you must specify one of these options.

`-weight weight_value`

Specifies a cost function weight for this group.

The *weight_value* argument must be a number between 0.0 and 100.0; the default is 1.0.

A weight of 0.0 eliminates the paths in this group from cost function calculations. Do not use very small values such as 0.0001. Smaller values can prevent the tool from implementing small improvements to the design.

If you use the *-weight* option when you add members to an existing group, the tool uses the new weight for the group.

Feedback

`-critical_range` *`range_value`*

Specifies a margin of delay for this group during optimization.

The *range_value* argument must be positive or 0.0; the default is defined by the *set_critical_range* command, whose default is 0.0.

A range of 0.0 means that only the most critical paths (the ones with the worst violation) are optimized. If you specify a nonzero range, other near-critical violating paths (one per endpoint) within that amount of the worst path are also optimized if possible.

To optimize more than one critical path to an endpoint, use a separate *group_path* command for each distinct critical path to that endpoint. To optimize all violating paths, specify a range value that is larger than any expected path violation.

`-from` *`from_list`*

Specifies the timing path startpoints. A valid startpoint is a clock, a primary input or inout port, a sequential cell, a clock pin of a sequential cell, a data pin of a level-sensitive latch, or a pin that has input delay specified.

If you specify a clock, all registers and primary inputs related to that clock are used as path startpoints. If you specify a cell, one path startpoint on that cell is affected.

You can use only one of the following options: *-from*, *-rise_from*, and *-fall_from*.

`-rise_from` *`rise_from_list`*

Specifies the timing path startpoints. This option is similar to the *-from* option, except that the path must rise from the specified objects.

If you specify a clock object, this option selects the startpoints launched by the rising edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: *-from*, *-rise_from*, and *-fall_from*.

`-fall_from` *`fall_from_list`*

Specifies the timing path startpoints. This option is similar to the *-from* option, except that the path must fall from the specified objects.

If you specify a clock object, this option selects startpoints launched by the falling edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: *-from*, *-rise_from*, and *-fall_from*.

Feedback

`-through` *`through_list`*

Specifies the timing path throughpoints. A valid throughpoint is a port, pin, or leaf cell. If you specify more than one throughpoint, they must be enclosed in either quotation marks ("") or braces ({}).

The path grouping applies only to paths that pass through one of the throughpoints.

You can use multiple *-through* options in a single command. If you use multiple *-through* options, the path grouping applies to paths that pass through each set of throughpoints in the order in which they were specified. In other words, the path must first pass through a throughpoint specified in the first *-through* option, then through a throughpoint specified in the second *-through* option, and so on for every *-through* option.

If you the *-through* option with the *-from* or *-to* options, the path grouping applies only if all the conditions are satisfied.

`-rise_through` *`rise_through_list`*

Specifies the timing path throughpoints. This option is similar to the *-through* option, but applies only to paths with a rising transition at the specified objects.

You can use multiple *-rise_through* options in a single command.

`-fall_through` *`fall_through_list`*

Specifies the timing path throughpoints. This option is similar to the *-through* option, but applies only to paths with a falling transition at the specified objects.

You can use multiple *-fall_through* options in a single command.

`-to` *`to_list`*

Specifies the timing path endpoints. A valid endpoint is a clock, a primary output or inout port, a sequential cell, a data pin of a sequential cell, or a pin that has output delay specified.

If you specify a clock, all registers and primary outputs related to that clock are used as path endpoints. If you specify a cell, one path endpoint on that cell is affected.

You can use only one of the following options: *-to*, *-rise_to*, and *-fall_to*.

`-rise_to` *`rise_to_list`*

Specifies the timing path endpoints. This option is similar to the *-to* option, but applies only to paths that rise at the endpoint.

Feedback

If you specify a clock object, this option selects the endpoints captured by the rising edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: *-to*, *-rise_to*, and *-fall_to*.

`-fall_to` *`fall_to_list`*

Specifies the timing path endpoints. This option is similar to the *-to* option, but applies only to paths that fall at the endpoint.

If you specify a clock object, this option selects the endpoints captured by the falling edge of the clock at its source, taking into account any logical inversions along the clock path.

You can use only one of the following options: *-to*, *-rise_to*, and *-fall_to*.

`-priority` *`priority_level`*

Assigns a priority to the command to resolve conflicting path selections between different *group_path* commands. By default, different *group_path* commands follow ordinary rules of priority to resolve conflicting path selections. For example, a command using *-from* and *-to* to select paths has priority over a conflicting command that selects a subset of those paths using *-through*, so the latter command is ignored for the paths that could be in either. By setting a higher priority in the command using the *-through* option, its path selection is honored, overriding the usual order of priority on paths in the intersection of the two groups. If unspecified, the priority is 0. It is recommended to set the priority for a *group_path* command to an integer greater than zero.

`-comment` *`comment`*

Specifies a comment string for the command.

The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out by the *write_sdc* or *write_script* command. The comment remains intact throughout the design flow.

Description

This command groups a set of paths or endpoints for cost function calculations in optimization and analysis. The delay cost function is the sum of all groups (weight * violation), where violation is the cost of the worst path in the path group. If no violation occurs within a group, the group cost is zero. The weight of the default group is 1.0.You can use path groups to optimize even though there might be larger violations in another group.

The *create_clock* command automatically creates a path group for a new clock with a weight of 1.0 and the same name as the clock name. By default, clock-gating check and asynchronous preset and clear check paths will be added to the clock group they relate to.

Feedback

The *time.use_special_default_path_groups* application option may be used to alter this behavior.

In presence of special inbuild path group, the tool follows the following precedence rules for assigning group paths:

Order of precedence from highest to lowest is: a) User defined group path b) Special inbuilt group path (async and clock_gating only) *set_app_options -name time.use_special_default_path_groups -value true* c) IO group path *set_app_options -name time.enable_io_path_groups -value true* d) Default clock group

By default, the tool allows pulling paths from special built-in path groups like: **async_default**, **clock_gating_default** into user-defined path groups, which is different from PrimeTime. To match PrimeTime precedence rule for group path, use the following application option:

set_app_options -name time.special_path_group_precedence primetime

To remove a path group, use the *remove_path_groups* command. To report path group information for a design, use the *report_path_groups* command.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example groups all endpoints clocked by CLK1A or CLK1B into a new group named group1 with a weight of 2.0.

```
prompt> group_path -name group1 \\
   -weight 2.0 -to {CLK1A CLK1B}
```

The following example adds OUT1 and ff34/D to the existing path group named ADDR.

```
prompt> group_path -name ADDR \\
   -to {OUT1 ff34/D}
```

The following example removes OUT1 and CLK2 from existing groups and places them in the default group.

```
prompt> group_path -default \\
   -to {OUT1 CLK2}
```

The following example groups all paths from inputs I1 and I2 to outputs O5 and O7 into a group named serious with a weight of 10.0.

```
prompt> group_path -name serious \\
   -weight 10.0 -from {I1 I2} -to {O5 O7}
```

Feedback

The following example groups the paths that begin at A1, pass through B1, then pass through C1, and end at D1 into a group named group2.

```
prompt> group_path -name group2 \\
   -from A1 -through B1 -through C1 -to D1
```

The following example groups the paths that begin at A1, pass through either B1 or B2, then pass through either C1 or C2, and end at D1 into a group named group3.

```
prompt> group_path -name group3 \\
   -from A1 -through {B1 B2} -through {C1 C2} -to D1
```

gui_add_annotation

Adds an annotation to the layout window.

Syntax

```
status gui_add_annotation
[-window window_name]
[-group group_type]
[-type shape_type]
[-symbol_type symbol_type]
[-symbol_size symbol_size]
[-text text]
[-color color]
[-pattern pattern]
[-width line_width]
```

Feedback

```
[-line_style line_style]
[-visible visible]
[-info_tip info_tip]
[-query_text query_text]
[-query_command query_command]
[-radius radius]
[-ruler_layer ruler_layer]
points
```

Data Types

```
window_name      string
group_type       string
shape_type       string
symbol_type      string
symbol_size      string
text             string
color            string
pattern          string
line_width       string
line_style       string
visible          boolean
info_tip         string
query_text       string
query_command    string
radius           float
points           list
ruler_layer      string
```

Arguments

`-window window_name`

Specifies the instance name of the layout window. If window name is omitted, the annotation will apply to all layout windows.

`-group group_type`

Specifies the annotation group. If group name is omitted, the *global* name is used.

`-type shape_type`

Specifies the type of annotation. The supported values for this option are

rect
line
arrow
polygon
polyline
text
symbol
ruler
manhattan_ruler

Feedback

circle
circular_ruler

The default is symbol, rect, or polygon if the number of points is 1, 2, or larger than 2 respectively.

`-symbol_type` *symbol_type*

Specifies the type of symbol annotation. This option is only valid when annotation type is symbol. The supported values for this option are

square
x
triangle
diamond

The default is x.

`-symbol_size` *symbol_size*

Specifies the size of symbol annotation. An even symbol size will grow one automatically to find the appropriate center point. The default symbol size is 25.

`-text` *text*

Specifies the annotation text.

`-color` *color*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes may be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette.

`-pattern` *pattern*

Specifies the annotation fill pattern. The default fill pattern is none. An empty value forces the tool to use the window default value, which is usually set to solid fill.

`-width` *line_width*

Specifies the annotation line width. The default line width is 1.

`-line_style` *line_style*

Specifies the annotation line style. The default line style is none. An empty value forces the tool to use the window default value, which is usually set to solid line.

Feedback

`-visible` *visible*

Specifies the visibility of the annotation. The default visible is true.

`-info_tip` *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_text` *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_command` *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
%x       the x position clicked in design coordinates
%y       the y position clicked in design coordinates
```

Feedback

`-radius` *radius*

Specifies the radius of circle annotation. This option is only valid when annotation type is circle.

`-ruler_layer` *ruler_layer*

Specifies the layer of the ruler annotation.

points

Specifies the points for the specified annotation type. The points are specified by a tool command language (Tcl) list in which each list element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.
- bbox_ul : the annotation is placed at the upper left of the bounding box of the object.
- bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

Feedback

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

Description

This command defines a new annotation and returns a collection containing that annotation if it is successful.

Examples

```
Create a green rectangle annotation.

prompt> gui_add_annotation -window Layout.1 \\
   -type rect -color green {{200 200} {777 777}}

Create a light_green rectangle annotation using light_green from the
 highcontrast palette.

prompt> gui_add_annotation -window Layout.1 \\
   -type rect -color light_green:highcontrast {{200 200} {777 777}}

Create a light_green x annotation of size 100 using light_green from the
 highcontrast palette.

prompt> gui_add_annotation -window Layout.1 \\
   -type x -symbol_size 100 -color light_green:highcontrast [list
 {1835.0010 119.2950}]

Create a red polyline annotation in the group Test1.

prompt> gui_add_annotation -window Layout.2 \\
   -group Test1 -type polyline -color red \\
   -width 2 {{123 456} {789 12} {200 200}}

Create a line between two cells A and B.

prompt> gui_add_annotation -window Layout.1 \\
   -type line [list [get_cells A] [get_cells B]]

Create a line between the center of largest rectangle of cell A and the
 center of
the largest rectangle of cell B.

prompt> gui_add_annotation -window Layout.1 \\
   -type line [list [list [get_cells A] center] [list [get_cells B]
 center]]

Create a line between the bottom left of cell A's bounding box and the
 middle of
the top of cell B's bounding box.

prompt> gui_add_annotation -window Layout.1 -type line \
```

Feedback

```
   [list [list [get_cells A] bbox_ll] [list [get_cells B] bbox_center 0.0
 0.5]]

Create a blue rectangle which displays the annotation points using the
 annotation_query
tcl procedure.

prompt> proc annotation_query { object window view } { \\
  return [get_attribute $object points] \\
  }

prompt> gui_add_annotation -window Layout.1 -type rect -color blue \\
  -query_text {=annotation_query %object %window %view} -info_tip
 {annotation points} \\
  {{110 110} {160 160}}

Create a circle annotation whose center is {100 100} and radius is 10.

prompt> gui_add_annotation -type circle -radius 10 {{100 100}}

Create a circle annotation whose center is {100 100} and boundary is at
 point {120 120}

prompt> gui_add_annotation -type circle {{100 100} {120 120}}

Create a circular ruler annotation with 3 circles (radius 20, 40, 100) at
 100, 100.

prompt> gui_add_annotation -type circular_ruler {{100 100} {120 100} {140
 100} {200 100}}

gui_add_image_view_file

Add image file to image view

Syntax

```
image_id gui_add_image_view_file
-window window_name
-file filename
[ -current ]
```

Feedback

Data Types

```
window_name  string
filename     string
image_id       string
```

Arguments

`-window` *window_name*

Specifies the name of the image view for which the data file is to be added.

`-file` *filename*

Specifies the data file to add to the image view.

If the file is an Image Data File ('.idf') file then the image and associated meta data will added.

If the file is a normal image file (PNG, JPEG, ...) then the image will be added with no associated data.

`-current`

Specifies the specified image is made current

By default the current image is not changed

Returns

image_id

A unique id for the added image for use in *gui_get_image_view_data* and *gui_set_image_view_data* commands.

Description

The *gui_add_image_view_file* command adds a data file generated by the *gui_write_window_image* command to the specified image view.

The data in the data file will be used to add the image to the view and populate the data associated with the displayed images.

Examples

The following example adds the image_view.idf file to the current image view.

```
shell> set view [gui_get_current_window -type ImageView]
shell> gui_add_image_view_file -window $view -file image_view.idf
```

Feedback

---

gui_add_missing_vias

Adds missing vias for the selected wires or nets.

Syntax

status *gui_add_missing_vias*

```
[-min_layer min_layer_name]
[-max_layer max_layer_name]
[-between_adjacent_layers_only]
[-quiet]
[object_list]
```

Data Types

```
min_layer_name  string
max_layer_name  string
object_list     collection
```

Arguments

`-min_layer min_layer_name`

Specifies the name of the minimum bottom layer to consider when adding vias.

`-max_layer max_layer_name`

Specifies the name of the maximum upper layer to consider when adding vias.

`-between_adjacent_layers_only`

Specifies that vias should be added only between adjacent routing layers. No generation of via stacks is allowed. This option is equivalent to using of sequence of gui_add_missing_vias with adjacent layers specified in -min_layer and -max_layer options for all pairs of adjacent layers

`-quiet`

Suppress all messages.

Feedback

object_list

Specifies the net name or net shape for which to create the via. If *object_list* is not specified, the command uses the global selection. If *object_list* is not specified and nothing is selected, the command issues an error message and does not modify the design.

Description

This command adds missing vias for unconnected wires in the GUI. Specify the wires for via insertion by selecting them in the GUI or by specifying the net names or net shapes to the command. For each selected wire, or wire on the selected net, the tool checks for overlaps with another wire, a pin shape or a port shape/terminal on a different layer on the same net. If an overlap is found and no via is present, the command ensures that vias exist so that these objects are connected.

The command considers the following:

Route Type

The route type of the new via is taken from the route type of the existing wire being connected. If there are two wires then the route type of one of the wires is used - which one is chosen is indeterminate.

Connection Point

The new via will be centered on the connection point between the two objects: wire-to-wire, wire-to-pin shape, or wire-to-port shape/terminal. The connection point is calculated by determining the overlap of the two shapes. The command snaps the center of the overlap using the layers and widths of the connecting objects.

Limitations

Vias inserted by this command on PG net wires are limited to only the selected wires and are not allowed for the whole net. This allows you to perform minor repairs and reduces the chance that you will accidently attempt to repair the whole power mesh. Repairing the entire power mesh would be prohibitively slow with this command and is better achieved by using separate power planning commands.

The vias created between PG net wires only use the simplified algorithms available in other route editing tools, such as the Stretch Wire tool and Create Via auto mode. If you need more control over via creation, use the *create_pg_vias* command or other tools available in the GUI.

Examples

The following example adds missing wires for all the wires on the net N1 between METAL and METAL3 layers.

Feedback

```
prompt> change_selection [get_nets N1]
prompt> gui_add_missing_vias -min_layer METAL -max_layer METAL3
```

---

gui_append_utable

Append data rows to an existing UserTable.

Syntax

string *gui_append_utable*

```
-name                  Name
-rows                  TCL_Data_List

-import                File_Name [-val_map ...] [-col_map ...] [-tsv_mode]
 [-ssv_mode]
-val_map               Column_Value_Map
-col_map               Column_Value_Map
[-tsv_mode]
[-ssv_mode]

-column                Name
[-expr]                Value

Name             String
File_Name        String
Column_Value_Map    TCL List of column value pairs
TCL_DataList     TCL List of String List
Value            Value String
```

Arguments

`-name` *Name*

The name of an existing UserTable that the new data rows should be added to.

`-rows` *TCL_Data_List*

A TCL list of string lists that match the number of columns.

`-import` *File_Name*

A value file that is imported and appended to the given UserTable.

Feedback

`-val_map` *`Column_Value_Map`*

A list of column-value pairs that are used to fill empty data values for a given column when importing a file.

`-col_map` *`Column_Value_Map`*

A list of column-value pairs that are used to map a table column name to the imported table column name. The default is to map to the same name. But if the name of a column in the imported file is different then use this option.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

Description

```
This command appends new data to and existing table. This can be done by
 either
appending a TCL list of lists as new rows, or by importing CSV files and
 appending
them. Also you have the ability to add a new column that can also be
 filled
with a math expression that can use +,-,* and / on referenced column
 values in
the same row.

When appending a TCL list of lists as new rows, row columns are filled
 left to right,
first to last, in a given list of lists. Extra data values in a row list
 are ignored
and if the row list is too short on values it will fill the extra columns
 with
empty fields. If the -rows argument is just a single list of values, it
 is
assumed to be only one row of values that will be added. Again extra row
 values
are ignored and missing row values are filled with empty fields.

Another way to add new rows to an existing table is to import another
 table and
append its content to this table. Use the -import option along with
 related options
-val_map and -col_map. Only columns that match the target table are
 imported
unless you use the -col_map option to map column names that have a
 different
name in the import table. Columns that don't match are filled with null
 or a default
```

Feedback

value if it is listed in the **-val_map** option.

Finally one can add a whole new column to an exsisting table that optionally can be
filled with a math expression that references data in other columns of the current row.
Expressions that reference other columns must surround the column with @{...} see
example below.

Examples

The following example appends two rows of static data given as a TCL list of lists
to the given UserTable that has three columns of data.

```
shell> gui_append_utable -name my_table -rows {
 ...      { /top/ModA  0.01  1000 }
 ...      { /top/ModB  0.03  5000 }
 ...   }
```

The following example first creates a TCL list of lists and then appends it to the
given UserTable.

```
shell> set rows {}
shell> ... loop through collection and set vars and append to list...
shell> lappend rows [list $cellname $delay $area]
shell> ...
shell> gui_append_utable -name MyTable -rows $rows
```

The following example appends a given CSV file to an existing table MyTable.
It also uses a column map to map the target column name like (edge) to the column
that matches that data in the CSV file (rise_fall). The columns in the
target table ("Extra Col" and sum) would be filled with null but by defining
a value map that maps the target column with a default value it then fills that
column with a default value if it is empty.

```
        set column_map {
  edge  rise_fall
  cap   capacitance
}

set empty_value_map {
  {Extra Col} {not used}
  sum         0
}
```

Feedback

```
gui_append_utable -name MyTable -import values.csv \\
  -val_map $empty_value_map -col_map $column_map
```

Finally below is an example of adding a new expression column to a table.

```
        # Create a table with 3 columns with data type double (postfix)
gui_create_utable -name MyTable -col {Label A:double B:double}

# Add some rows:
gui_append_utable -name MyTable -rows {
  {LabelA 0 1}
  {LabelB 2 3}
  {LabelC 4 5}
}

# Now lets add a new expression column:
# NOTE: referenced column names are surrounded by @{...}
gui_append_utable -name MyTable -column Expr:double -expr { 100 * (@{A} +
 @{B}) }

# Now add a new row (Note: Requires an empty value for the expr column
 added in the previous step!):
gui_append_utable -name MyTable -rows {LabelD 11 22 {}}
```

Feedback

gui_change_charts_model

Change data in model used in chart's plots

Syntax

```
status gui_change_charts_model
-model model_id
[ -column string ]
{ -add | -delete | -modify | -calc | -query }
[ -header string ]
[ -type string ]
[ -expr string ]
```

Data Types

model_id int

Arguments

`-model` *model_id*

Model to change (previously created by *gui_create_charts_model* command).

`-column` *string*

The column name or number to delete, modify, calculate or query.

`-add`

Add column to model. The *expr* option specifies the expression to use to calculate the values in the new column.

`-delete`

Delete column from model. Use the *column* option to specify the column to delete.

Note: the original columns of the model cannot be deleted, only newly added columns can be removed after they are created.

`-modify`

Modifies the values in an existing column. Use the *column* option to specify the column to modify and the *expr* option to specify the expression to use to calculate the new values in the column.

Note: the original columns of the model cannot be modified, only newly added columns can be modified are created.

Feedback

`-calc`

Calculate values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the expression to use to calculate the values.

The calculated values are returned by the command. The model is not modified.

`-query`

Query values from model. Use the *column* option to specify the default column for the values and the *expr* option to specify the expression to use to query the values.

The expression should return true or false and the returned values are those where the expression evaluates to true.

The queried values are returned by the command. The model is not modified.

`-header` *`string`*

Specifies the name of the header when adding or modifying a column.

`-type` *`string`*

Specify the type of the new column for *add*, *modify* options.

`-expr` *`string`*

Specifies the expression to use when adding, modifying, calculating or querying values of a column of the model.

The expression can use tcl variable names that match the column name (as long as the column name is a legal tcl variable name). A few extra variables are also allowed:

- column : current column
- row : current row
- pi : value of pi (3.141592653...)
- NaN : Special 'not a number' real value that can be used to indicate absence of data.

A number of extra functions are allowed as well as the normal tcl expression functions:

- column : get column value for row
- row : get row value for column
- cell : get cell value for row and column

Feedback

- setColumn : set column value for row
- setRow : set row value for column
- setCell : set cell value for row and column
- header : get header value for column
- setHeader : set header value for column
- type : get type for column
- setType : set type for column
- map : map row number to range
- bucket : get bucket for column value
- norm : normalize column value
- rand : get random number
- rnorm : get normaized random number
- color : get color from name
- remap : map column value to range
- timeval : get time value from column with time format

Some special character sequences in the expression are replaced with model values before the expression is evaluated.

- @<n> : value for specified column number (<n>) for current row.
- @c : column number.
- @r : row number.
- @nc : number of columns.
- @nr : number of rows.
- @v : value for current row and column.
- @{<name>} : value for specified column name (<name>) for current row.
- #{<name>} : column number for specified column name (<name>)

Normally the '@' symbols return data in the value format but this can be forced to be a string by using '@#' instead of '@'.

Feedback

Description

Change data in existing model to add, delete or modify columns for use in charts.

Examples

The following example adds a new column to the model where the value is the sum of the first two columns.

```
shell> gui_change_charts_model -model $model -add -expr {column(0) +
 column(1)} -header Sum
```

See Also

- gui_create_charts_plot
- gui_define_charts_proc

---

gui_change_error_highlight

Manipulates error objects highlight sets.

Syntax

string *gui_change_error_highlight*

-add | -remove [-color *color_id*] [-selected | -all | -all_visible] [-type *error_type_list*] [-layer *layer_strings*] [-include_net *nets* | -exclude_net *nets*]

```
color_name        A color name
error_type_list   A Tcl list of error type names
layer_strings     A Tcl list of layer strings
nets              A Tcl list of net names or a collection of nets
```

Arguments

`-add | -remove`

Required mutually exclusive option which specifies that the errors are added or removed from the error highlight set. If -add, the specified errors become drawn in the given highlight color. If -remove, the specified errors become drawn in the default violation color.

`-color <color_id>`

This option specifies the color for the operation. If a color is given with the -color option, it must be one of the supported color names: blue, green, light_blue, light_green, light_orange, light_purple, light_red, orange, purple, red, yellow. If -color option is provided with the -add option, the specified color will be used to color the specified errors in the given color. If -color option is provided with the -remove option, errors in the specified color highlight set will be removed from

Feedback

the highlight set and will become drawn in the default violation color. When given with the -remove option, this option is mutually exclusive with -selected, -all, -all_visible, -type, -layer, -include_net, and exclude net options.

`-selected`

This option is mutually exclusive with -all, -all_visible, -type, -layer, -include_net and -exclude_net. If this option is present, currently selected errors in the current tab error list become highlighted in the specified color.

`-all`

This option is only meaningful with the -remove and is mutually exclusive with -color, -all_visible, and -selected. When given with the -remove option, removes highlight colors from all errors in all open error views.

`-all_visible`

This option is mutually exclusive with -selected, -type, -layer, -include_net and -exclude_net. If this option is given with the -add option, currently visible errors in the current tab error list become highlighted in the specified color. If this option is given with the -remove option, all error highlight colors are removed from currently visible errors in the current tab error list. They become drawn in the default violation color.

`-type <error_type_list>`

This option is mutually exclusive with -selected and -all_visible. It may be combined with -layer, and -include_net or -exclude_net. Errors that are of one of the given types become highlighted in the specified color. If combined with layer and/or net specifications, errors must match all given specifications to be selected for highlighting.

`-layer <layer_string_list>`

This option is mutually exclusive with -selected and -all_visible. It may be combined with -type, and -include_net or -exclude_net. Errors that are of one of the given layers become highlighted in the specified color. If combined with error type and/or net specifications, errors must match all given specifications to be selected for highlighting.

`-include_net <nets>`

This option is mutually exclusive with -selected, -all_visible and with -exclude_net. It may be combined with -type and -layer. Errors that are associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

Feedback

`-exclude_net <nets>`

This option is mutually exclusive with -selected, -all_visible and with -include_net. It may be combined with -type and -layer. Errors that are not associated with one of the given nets become highlighted in the specified color. NULL net is specified with an empty net name: "". If combined with error type and/or layer specifications, errors must match all given specifications to be selected for highlighting.

Description

The command specifies the color to use in drawing the specified errors. Errors can be drawn in a highlight color by adding them to the error highlight color set. Errors can be removed from the error highlight color set and revert to being drawn in the default violation color. The command behavior is determined by combinations of the options as follows:

Adding errors to a highlight set:

If -color is given with the -add option, the specified errors are added to the error highlight color set and become draw in the specified color. The specified color becomes the current error highlight color.

If -color is omitted with the -add option, the specified errors are added to the current error highlight color set and become draw in the current error highlight color.

If -selected is given with the -add option, selected errors are added to the error highlight color set and become draw in the specified color.

If -all_visible is given with the -add option, all visible errors in the current tab error list are added to the error highlight color set and become draw in the specified color.

If -type, -layer -include_net or -exclude_net is given with the -add option, visible errors in the current tab error list matching the given criteria are added to the error highlight color set and become drawn in the specified color.

Removing errors from a highlight set:

If -color is given with the -remove option, all errors in the specified error highlight color set are removed and become drawn in the default violation color.

If -selected is given with the -remove option, selected errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all is given with the -remove option, all errors are removed from respective error highlight color sets and become drawn in the default violation color.

If -all_visible is given with the -remove option, all visible errors in the current tab error list are removed from respective error highlight color sets and become drawn in the default violation color.

Feedback

If -type, -layer -include_net or -exclude_net is given with the -remove option, visible errors in the current tab error list matching the given criteria are removed from the respective error highlight color set and become drawn in the default violation color.

Examples

The following example puts the currently selected errors in the blue error highlight set:

gui_change_error_highlight -add -color blue -selected

The following example puts "Short" type errors associated with a net named "C0_9_" in the red error highlight set:

gui_change_error_highlight -add -color red -type {Short} -include_net {C0_9_}

The following example puts "Floating Port" type errors not associated with NULL net in the green error highlight set. Please note the use of parentheses as delimiters. Since the expected argument for -type and -exclude_net options is a list of strings, multi-word strings or empty string signifying NULL net must be delimited:

gui_change_error_highlight -add -color green -type {{Floating Port}} -exclude_net {{}}

The following example adds all visible errors in the current tab error list to the light_red highlight set:

gui_change_error_highlight -add -color light_red -all_visible

The following example removes all errors from all error highlight sets:

gui_change_error_highlight -remove -all

The following example removes errors in the red color highlight set from the highlight set:

gui_change_error_highlight -remove -color red

The following example removes all visible errors in the current tab error list from highlight sets:

gui_change_error_highlight -remove -all_visible

See Also

- gui_set_selected_errors

---

gui_change_highlight

Manipulate the set of globally highlighted objects.

Syntax

string *gui_change_highlight*

Feedback

```
[-add | -remove | -toggle]
[-color color_id | -all_colors]
[-collection clct]

string          color_id
collection      clct
```

Arguments

`-add`

Use -add to highlight a collection of objects in a color specified with color. If -color is not specified, the current color is used. You cannot use -all_colors with -add. You must specify a collection with -collection. If -remove or -toggle are not specified, then -add is implied.

`-remove`

Use -remove to remove highlighting from objects. Use -collection to remove highlighting from specific objects. Use -color to remove highlighting from objects of a specific color. Use -all_colors to remove all highlighting. If you specify a collection, you cannot specify colors.

`-toggle`

Use -toggle to toggle the highlight state of a collection of objects. You must use -collection with -toggle, and you cannot use -color or -all_colors. Toggling an object that is highlighted will cause it to no longer be highlighted. Toggling an object that is not highlighted with cause it to be highlighted with the current color. If no operation is specified, then -add is assumed.

`-color` *`color_id`*

Specifies the color to be used for the highlight operation. This is mutually exclusive with -all_colors. The allowed colors are blue, light_blue, yellow, purple, light_purple, orange, light_orange, red, light_red, green, and light_green. If neither -color nor -all_colors is specified, then the current highlight color is assumed. You cannot use -color with -toggle.

`-all_colors`

This option is only valid with -remove. Use this option to clear all highlight colors.

Description

The gui_change_highlight command is used to operate on the set of highlighted objects. Objects can be added or removed from the set, or their presence can be toggled as described above. The set has a current color that can be modified with gui_set_highlight_options. The current color is used as needed when no color is specified.

The tool provides eleven built in highlight colors with the names yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

Feedback

The gui_change_highlight command uses colors from the highlight color palette.

Examples

Highlight in green all cells with names matching foo*.

shell> gui_change_highlight -color green -collection [get_cells foo* -hierarchical -all]

Remove highlights from all objects in the collection returned by the get_cells command.

shell> gui_change_highlight -remove -collection [get_cells foo* -hierarchical -all]

Clear all objects with blue highlights.

shell> gui_change_highlight -remove -color blue

Clear objects with the current highlight color.

shell> gui_change_highlight -remove

Clear all highlights.

shell> gui_change_highlight -remove -all_colors

Toggle the highlight state of all objects in a collection returned by the get_cells command.

shell> gui_change_highlight -toggle -collection [get_cells foo*]

- gui_set_highlight_options
- gui_get_color_value

---

gui_change_layer

Sets the layer of pins, ports, or net shapes.

Syntax

collection *gui_change_layer*

```
-object object
-layer layer
```

Data Types

```
object  collection
layer   string
```

Feedback

Arguments

`-object` *object*

Specifies the collection of objects for which to change the layer.

`-layer` *layer*

Specifies the name of the layer to use.

Description

The *gui_change_layer* command is used to change the layer of block pins, ports/terminals, and net shapes. Changing the layer of net shapes and terminals creates new shape objects and deletes the existing shapes. The *gui_change_layer* command updates the selection to contain the new objects. Use the *set_object_layer* command instead to avoid updating the selection.

Examples

The following example changes the layer of the clk_enable block pin.

```
prompt> gui_change_layer -object [get_pins TOP/LEVEL_1/clk_enable] -layer
 METAL2
```

See Also

- get_layers
- set_object_layer

---

gui_change_schematic

Performs abstraction on the current or specified schematic view.

Syntax

string *gui_change_schematic*

```
-type abstraction_name
-operation operation_name
-clct objects
[-window window_name]
```

Data Types

```
abstraction_name    string
operation_name      string
objects             collection
window_name         string
```

Feedback

Arguments

`-type` *abstraction_name*

Name of abstraction type. Currently supported types: "Hierarchy".

`-operation` *operation_name*

Name of operation to be applied for the specified abstraction type. Currently supported operations: "Expand", "Collapse".

`-clct` *objects*

The collection of objects in the target schematic to which the specified abstraction operation will be applied.

`-window` *window_name*

Optionally specifies the target schematic to which the abstraction is applied. If not specified, the current application schematic will be the target.

Description

The command applies the specified abstraction operation to the specified objects within the target schematic view.

Examples

The following example collapses currently selected modules within the current schematic view.

```
prompt> gui_change_schematic -type Hierarchy -operation Collapse -clct
  [get_current_selection]
```

---

gui_change_selection_utable

Change Current Selection by adding objects named in the given table.

Syntax

string *gui_change_selection_utable*

```
-name         Table_Name
[-obj_col     Col_Name]
[-filter      Filter]

Table_Name    String
Col_Name      String
Filter        Table Filter String
```

Feedback

Arguments

`-name` *`Table_Name`*

The name of the user table to use for finding object names to add to the current selection.

`-obj_col` *`Col_Name`*

The column name containing object names with a data type set. By default it uses the full_name and object_class type or named columns.

`-filter` *`Filter`*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

Description

```
This command takes a table name and if a filter is given, reduces the
 rows
to those that match the filter and then tries to add to the current
 selection
any object names found in those table rows. The object names are searched
 for
in the column given by the -obj_col command argument. By default it uses
the full_name and object_class type or named columns to determine object
 names
to add to the current selection.
```

Examples

```
The following example adds all object with the object names found in the
column 'pins' that match the filter '*ALU*'.

shell> gui_change_selection_utable -name my_table -obj_col pins -filter
 {pins =~ *ALU*}
```

---

gui_change_via_def

Sets the via definition for the specified vias.

Syntax

string *gui_change_via_def*

```
-via via
-via_def via_def
```

Data Types

```
via      collection
via_def  string
```

Arguments

`-via via`

Specifies the collection of vias for which to change the via definition.

`-via_def via_def`

Specifies the name of the new via definition.

Description

The *gui_change_via_def* command is used to change the via definition of vias. By changing the via definition, new vias with different via definitions might be created. The *gui_change_via_def* command updates the selection to contain the new vias. Use the *set_via_def* command instead to avoid updating selection.

Examples

The following example changes the via definitions on a via named VIA_S_92587 to VIA34.

```
prompt> gui_change_via_def -via [get_vias VIA_S_92587] -via_def VIA34
```

See Also

- create_via_def

---

gui_change_via_size

Sets the attributes for the number of rows and columns in a via collection.

Syntax

status *gui_change_via_size*

```
-via via
[-rows rows]
[-columns columns]
```

Data Types

```
via      collection
rows     integer
columns  integer
```

Arguments

`-via via`

Specifies the collection of vias for which to change the array size.

`-rows rows`

Specifies the number of rows in the via array.

`-columns columns`

Specifies the number of columns in the via array.

Description

The *gui_change_via_size* command changes the number of rows and columns of vias. By changing the via size, new vias with a different via definitions might be created. The *gui_change_via_size* command updates the selection to contain the new vias. Use the *set_via_def* command instead to avoid updating the selection.

Examples

The following example changes the array size on a via named VIA_S_92587 to two rows and two columns.

```
prompt> gui_change_via_size -via [get_vias VIA_S_92587] -rows 2 -columns
 2
```

Feedback

See Also

- get_vias
- set_via_def

---

gui_check_drc_errors

Checks for DRC errors on specified objects by using the same DRC mechanism that the interactive route editing tools use.

Syntax

```
int gui_check_drc_errors
[-of_objects objects]
[-limit_area {{llx lly} {urx ury}}]
[-layers layer_list]
[-honor_ndr true | false]
[-rules rule_types]
[-filter_same_net_spacing true | false]
[-check_fill true | false]
[-max_error_limit error_limit]
[-max_shape_limit shape_limit]
[-max_processing_time time_limit]
[-show]
```

Data Types

```
objects          collection
llx              float
lly              float
urx              float
ury              float
layer_list       collection
rule_types       list
error_limit      integer
shape_limit      integer
time_limit       integer
```

Arguments

`-of_objects objects`

Specifies a collection of net shape and via objects on which the tool performs the DRC checks. By default the DRC check is performed on the selection.

`-limit_area {{llx lly} {urx ury}}`

Specifies a rectangular area in which the tool performs the DRC checks. The tool checks only those shapes of the specified objects that are enclosed within the area or that intersect the bounding box that defines the area.

Feedback

`-layers` *`layer_list`*

Specifies the layers which to check. By default, the tool checks objects on all layers.

`-honor_ndr true | false`

Specifies whether the tool checks the supported nondefault routing rules. If this is not specified, the return value from *get_edrc_setting -honor_ndr* is used as default.

`-rules` *`rule_types`*

Specifies the types of DRC rules that the tool checks. The *rule_types* list can contain one or more of the following DRC error types:

```
Adjacent Min Edge Length
All
DPT Odd Cycle
DPT Pre-color
Enclosed Via Spacing
End-of-Line Spacing
General Via Spacing
Metal Span Spacing
Metal Width
Minimum Edge
Minimum Length and Area
Open
RDL Acute Angle
RDL Right Angle
Short
Spacing
Via Density
Via Enclosure
```

All can be used as the list of all other rules except *Open*. If you do not specify this option, the tool uses those relevant option values returned by the *get_edrc_setting* command.

`-filter_same_net_spacing true | false`

Specifies whether the tool ignores spacing violations between objects on the same net. If this is not specified, the return value from *get_edrc_setting -filter_same_net_spacing* is used as default.

`-check_fill true | false`

Specifies whether the tool to check shapes inside fill cells. If this is not specified, the return value from *get_edrc_setting -check_fill* is used as default.

`-max_error_limit` *`error_limit`*

Overrides the maximum number of DRC errors that the tool reports.

Feedback

A zero or a negative value allows an unlimited number of errors.

If this option is not specified, the return value from *get_edrc_setting -max_error_limit* is used as default.

If the *error_limit* or default limit is reached, the tool issues a warning message in the terminal window, the console log view, and output log file, and then stops writing out further messages.

`-max_shape_limit` *`shape_limit`*

Overrides the maximum number of shapes that the tool can check.

A zero value allows an unlimited number of shapes.

If this option is not specified, the return value from *get_edrc_setting -max_shape_limit* is used as default.

If the number of objects to be checked exceeds *shape_limit*, the command exits without checking. A warning message is issued in the terminal window and the console log view.

`-max_processing_time` *`time_limit`*

Specifies the maximum processing time in seconds that the tool can check. If this is not specified, the return value from *get_edrc_setting -max_processing_time* is used as default. The DRC checking terminates when the time limit is reached.

`-show`

Open the error browser to show violations.

Description

This command performs design rule checks on the specified objects and returns the number of violations found.

The command uses the same DRC mechanism that the route editing tools use during interactive editing operations. The tool writes the violations in the editor DRC error view and loads it into the error browser when error browser opens.

The editor DRC error view is associated with the current top-level design. This error view remains open after error checking finishes to ensure the validity of the returned collection of objects with violations. The tool closes the editor DRC error view automatically if you close the design or end the GUI session.

The editor DRC error view associated with the top-design is named *current_top_design_CEL_name*_edrc.err by default. You can retrieve the name of the editor DRC error view, including the version, as an attribute of the top-level design. The attribute name is *editor_error_view_name*.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks the selected objects for DRC errors, writes the violations into the editor DRC view, and loads the view into the error browser.

```
prompt> gui_check_drc_errors -show
```

The following example checks the net shapes inside the region *{{0 0} { 50 50} }* on METAL1 layer for *Minimum Edge* rule.

```
prompt> gui_check_drc_errors -limit_area {{0 0} { 50 50} }\\
   -rules {"Minimum Edge"} -layers METAL1 -show
```

---

gui_clear_error_data_filter

Remove the filter from error data.

Syntax

string *gui_clear_error_data_filter*

Description

Remove the filter and restore visibility of errors. Errors may remain hidden based on null net association or fixed status state if the "Hide Null-Net Errors" option or the "Hide Fixed Errors" option has been set.

Examples

The following example removes the error data filter

gui_clear_error_data_filter

Feedback

---

gui_clear_selected_errors

Clears selection in the Error Browser.

Syntax

string *gui_clear_selected_errors*

Description

Clears selected errors in the Error Browser.

Examples

The following example clears selected errors:

gui_clear_selected_errors

See Also

- gui_error_browser
- gui_get_errors
- gui_set_current_errors
- gui_set_selected_errors

---

gui_close_error_data

Removes an error data file from the error browser.

Syntax

```
status gui_close_error_data
[error_data]
```

Data Types

```
error_data        collection
```

Feedback

Arguments

error_data

A collection of physical DRC error data objects to remove from the error browser. A collection of the error data or the error data name can be used to remove it from the error browser.

Description

The *gui_close_error_data* command removes the given error data from the GUI error browser. If no error data is given, then the command removes all error data from the error browser and hides the error browser.

When a command opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The *gui_open_error_data* command opens an error data if necessary. It does not increment the open_count if the error data is already open and in memory. If the *gui_open_error_data* command increments the open_count, then a subsequent call to *gui_close_error_data* for the same error data decrements the open_count. Otherwise, a subsequent call to *gui_close_error_data* simply removes the error_data from the error browser without decrementing the open_count.

Examples

The following example removes the physical DRC error data file that is named "my_design_dppinassgn.err" from the error browser.

```
prompt> gui_close_error_data "my_design_dppinassgn.err"
1
```

The following example removes all physical DRC error data file from the error browser and hides the error browser.

```
prompt> gui_close_error_data
1
```

---

gui_close_utable

Close and free the given list of UserTables in memory.

Syntax

string *gui_close_utable*

```
-names   Table_Names

Table_Names     String List
```

Arguments

`-names` *`Table_Names`*

The list of table names to close and free in memory.

Description

```
This command closes and frees all the table names given by the user. If
 the
table was in read only mode (streaming), then the connection to the table
file is closed.
```

Examples

The following example closes a list of user tables.

```
shell> gui_close_utable -names {my_table1 my_table2}
```

See Also

---

gui_close_window

Close the specified window

Syntax

```
status gui_close_window
{ -window window_id | -type window_type | -all }
[ -exact_type_match ]
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-window window_id`

Specifies the window name id.

Any matching window of this name will be closed.

This option precludes the *-type* and *-all* options.

`-type window_type`

Specifies the window type id. Any matching window of this type will be closed.

If the *-exact_type_match* options is not specified then types derived from this window type will also be closed. Derived types are created with the *gui_create_window_type* command.

This option precludes the *-window* and *-all* options.

`-all`

Specifies that we want to close all the windows.

This option precludes the *-window* and *-type* options.

`-exact_type_match`

Specifies that types derived from the specified type are excluded when the *-type* option is specified.

Note: this option should only be used with the *-type* option.

Feedback

Description

This command closes the specified window(s).

Windows can be specified by name, type or as all windows.

Examples

The following examples will create a toplevel window and a child layout view window, then close the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> gui_close_window -window $x
```

---

gui_connect_charts_signal

Connect to charts signal

Syntax

```
status gui_connect_charts_signal
{ -view view_name | -plot plot_name }
-model model_ind
-from signal_name
-to tcl_proc
```

Data Types

```
view_name     string
plot_name     string
model_ind     integer
signal_name   string
tcl_proc      string
```

Feedback

Arguments

`-view` *`view_name`*

Charts view to connect to.

`-plot` *`plot_name`*

Plot to connect to.

`-model` *`model_ind`*

Model index.

`-from` *`signal_name`*

Signal name to connect to.

Supported names are:

objIdPressed (id proc) plot object clicked on with mouse

annotationIdPressed (id proc) plot or view annotation clicked on with mouse

chartObjsAdded (non-id proc) objects added to chart

`-to` *`tcl_proc`*

Tcl procedure to call when the signal is emitted.

For plot an id procedure is called with three arguments (view, plot and object_id) and a non-id procedure is called with two arguments (view, chart).

For view an id procedure is called with two arguments (view, object_id) and a non-id procedure is called with one arguments (view).

Description

Connects signals emitted from charts events to tcl callbacks.

Examples

The following example calls chartObjPressed proc when object in plot pressed.

```
shell> gui_connect_charts_signal -plot $plot -from objIdPressed -to
 chartObjPressed
```

See Also

- gui_create_charts_plot

Feedback

gui_create_3dic_trace_view

Trace and show bump-bump cross-die connectivity for the top-level system in a flattened 2d view.

Syntax

```
status gui_create_3dic_trace_view
-object collection
```

Data Types

```
collection   bump/port/net/term
```

Arguments

`-object` *collection*

Take the collection of bump/port/net/term for which the trace view will be drawn. Users can use the current selection, or a nested get_ like "[get_nets B_DQb74]". Currently it just takes singular collection.

Description

With the given object, this command can trace and show bump-bump cross-die connectivity for the top-level system in a flattened 2d view.

Examples

The following example will identify all global and local nets associated with net "B_DQb74", collect connected nets/bumps/terminals/ports and present the connectivity topology across different dies on a new view.

```
prompt> gui_create_3dic_trace_view -object [get_nets B_DQb74]
```

See Also

- gui_show_connectivity

gui_create_attrgroup

Creates a group of attributes for an object type.

Syntax

```
status gui_create_attrgroup
-class design_object
-name name
[-attr_list {{attr_1}...{attr_n}}]
```

Feedback

Data Types

```
design_object      string
name               string
attr_1             string
attr_n             string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the name of the attribute group to be created for the specified object type.

`-attr_list {{attr_1}...{attr_n}}`

Lists and orders the attributes to be included in the group.

Description

The *gui_create_attrgroup* command creates a new attribute group for a specific type of design object. The command adds the attribute group to the display in GUI tools, such as the Properties dialog box, List views, layout view InfoTips, and other graphic windows.

An attribute can be assigned to more than one attribute group at the same time.

The order of the attributes in an attribute group is important and is set by the *-attr_list* option when you create the group. Use the *gui_update_attrgroup* command if you need to change or reorder the attribute list for an attribute group.

Examples

```
prompt> gui_create_attrgroup -class Cell -name "Hierarchy" \\
   -attr_list { "Name" "Hierarchical" "Owning Cell"
   "isPhysConstraint" "Hard Macro" "Num Children" "Num Nets"
   "Num Pins" "Utilization" "Area" "Aspect Ratio" "Min Aspect"
   "Max Aspect" "Min Area" "Max Area" "Area / 1M" "Hier Req Area / 1M"
   "Reference" "Logical Name" "FullName" }

prompt> gui_create_attrgroup -class Cell -name "Edit" \\
   -attr_list { "Name" "isPhysConstraint" "Orientation"
   "Location" "Bounding Box" "Fixed Location" "Is Resizable"
   "Hard Macro" "Placed" "Is IO" "Off Litho Grid" "FullName" }

prompt> gui_create_attrgroup -class Pin -name "Timing" \\
   -attr_list { "Name" "Is Clock" "Slew"  "slack_max" }
```

Feedback

```
prompt> gui_create_attrgroup -class Net -name "Timing" \\
   -attr_list { "Name" "Lumped C" "Total Lumped C"
   "Lumped Resistance" }
```

See Also

- gui_delete_attrgroup
- gui_list_attrgroups
- gui_update_attrgroup

---

gui_create_block_diagram

Creates a block diagram view for the hierarchy cells specified by cell names or a collection. If no cell name or collection is specified, current selection is used. If there is no selection, the top-level design is used.

Syntax

string *gui_create_block_diagram*

```
[collection]
[-cells cellNames]
[-expanded]
```

Data Types

```
collection  collection
cellNames   list
```

Arguments

collection

Specifies a collection of hierarchy cells; the collection is used to initialize the block diagram view. If there is only one hierarchy cell in the collection, it is used as the root of the block diagram with all the hierarchy blocks it contains as the contents. If there are multiple hierarchy cells in the collection, a common hierarchy parent is determined and used as the root for block diagram and its contents are expanded to make the specified blocks visible.

This option is mutually exclusive with *-cells* option. Specify either a collection or a list of cell names but not both. If neither is specified, the current selection is used. In there is no selection, the top-level design is used.

-cells *cellNames*

Specifies a Tcl list of hierarchy cell names; the list is used to initialize the block diagram view. If only one hierarchy cell is specified, it is used as the root of the block diagram with all its child hierarchy blocks as the contents. If multiple

Feedback

hierarchy cells are specified, a common hierarchy parent is determined and used as the root for block diagram and its contents are expanded to make the specified blocks visible.

This option is mutually exclusive with the *collection* argument. Specify either a collection or a list of cell names but not both. If neither is specified, the current selection is used. In there is no selection, the top-level design is used.

`-expanded`

Display only buses in the block diagram without trying to bundle the buses together. By default, buses are bundled to create a more abstract block diagram view.

Description

The command generates a block diagram view of the currently selected design and hierarchy cells.

Examples

Each of the following examples generate a block diagram of hierarchical cell named RAM_1. The first command selects cell RAM_1. The second and third commands generate a block diagram of RAM_1 where its buses are bundled (not expanded). The last command generates a block diagram with buses the of RAM_1 unbundled.

```
prompt> change_selection [find cell RAM_1]
prompt> gui_create_block_diagram -cells {RAM_1}
prompt> gui_create_block_diagram [get_selection]
prompt> gui_create_block_diagram [get_selection] -expanded
```

See Also

- get_selection
- change_selection

---

gui_create_category_rule

Creates a category rule for automatic generation of one or more object categories.

Syntax

string *gui_create_category_rule*

```
[-name rule_name]
[-filter filter_spec]
-category category_spec
[-builtin]
```

Feedback

Data Types

```
rule_name           string
filter_spec         string
category_spec       string
```

Arguments

`-name rule_name`

Specifies the name of the category rule to be created. If this option is omitted, a unique new rule name is automatically generated.

`-filter filter_spec`

Specifies the filter. The basic form of a filter conditional expression is a series of relations joined together with && (and), || (or), and ! (not) operators. Parentheses are used to override precedence. The basic relation is either a Boolean attribute or a comparison of one non-Boolean attribute with another or with a constant value using relational operators.

For example, a filter expression can have any of the following forms:

- *-filter {endpoint_clock_is_propagated}* (Boolean attributes)
- *-filter {(slack < 0)}* (Comparison with a literal number)
- *-filter {(path_group.full_name == "inputs")}* (Comparison with a literal string)
- *-filter {(startpoint_clock.full_name == endpoint_clock.full_name)}* (Comparison of attributes)

Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection. The following relational operators are supported:

- == (Equal)
- *!*= (Not equal)
- =~ (Matches pattern)
- *!*~ (Does not match pattern)
- &~ (Contains all elements)
- |~ (Contains some elements)
- > (Greater than)
- < (Less than)

Feedback

- >= (Greater than or equal to)
- <= (Less than or equal to)

The matching operators are used to match wildcard regular expressions. The containment operators are used to compare space-separated set or list attributes.

`-category` *`category_spec`*

Specifies the category. The category specification can be fixed literal text, or it can include an optional object attribute name enclosed in angle brackets; for example, *-category <path_type>*. Additional literal text is optionally allowed to the left and to the right of the angle brackets; for example *-category {Path Type: <path_type>}*. Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection; for example, *-category <startpoint_clock.full_name>*.

When a category rule is "executed" later in the GUI, a separate category (bin of objects) is generated for each unique value of the attribute specified by the *-category* option. (The GUI "category-rule-execution engine" examines attribute values for an input set of objects.)

`-builtin`

Indicates that the rule being created belongs to the built-in group of category rules. If this option is omitted, the rule being created does not belong to the built-in group.

The built-in group of category rules is a group of category rules that are created before any non-built-in rules. This group of rules includes both built-in rules created by the tool (at tool startup time) and built-in rules that you create before creating any non-built-in rules.

Description

This command creates a category rule. If rule creation is successful, the command returns the name of the newly-created category rule; otherwise, it returns an empty string. After a category rule has been created, it can be used later (at "category-rule execution time" in the GUI) with other rules to generate one or more object categories.

Examples

This example creates a simple category rule:

```
prompt> gui_create_category_rule -name pathgroups \\
        -category <path_group.full_name>
pathgroups
```

Feedback

This example creates a simple filtering rule:

```
prompt> gui_create_category_rule -name {Negative Slack} \\
        -category {Failing Paths} -filter {slack < 0}
Negative Slack
```

This example creates a regular expression filtering rule:

```
prompt> gui_create_category_rule -name {ATPG Sessions} \\
        -category {ATPG Sessions} -filter {session_name =~ "atpg*"}
Negative Slack
```

This example creates a set or list containment filtering rule:

```
prompt> gui_create_category_rule -name {Through CPU and CTRL} \\
        -category {Through CPU and CTRL} -filter { blocks &~ "CPU CTRL"}
Negative Slack
```

See Also

- gui_list_category_rules
- gui_remove_category_rules

---

gui_create_charts_arrow_annotation

Create arrow annotation in view or plot

Syntax

```
arrow_id gui_create_charts_arrow_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-start position
-end position
[ -line_width length ]
[ -fhead string ]
[ -thead string ]
[ -mid_head string ]
[ -angle angles ]
[ -length lengths ]
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
length           string
angles           string
lengths          string
```

Feedback

```
name_value_list  string
arrow_id         annotation_id
```

Arguments

`-view` *view_name*

Charts View to add annotation to.

`-plot` *plot_name*

Plot to add annotation to.

`-id` *string*

Optional identifier string for annotation.

`-tip` *string*

Optional tip string for annotation.

`-start` *position*

Start point of the arrow line.

`-end` *position*

End point of the arrow line.

`-line_width` *length*

Width of the connecting line.

`-fhead` *string*

Front arrow head type.

One of triangle, stealth, diamond, line or none.

`-thead` *string*

Tail arrow head type.

One of triangle, stealth, diamond, line or none.

`-mid_head` *string*

Mid arrow head type.

`-angle` *angles*

Angle of arrow heads.

Use single value for same angle for both front and tail heads. Use two values for different angle for front and tail heads.

Feedback

`-length` *lengths*

Length of arrow heads.

Use single value for same length for both front and tail heads. Use two values for different length for front and tail heads.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

arrow_id

Returns id of created annotation.

Description

Add an arrow annotation to plot or view.

The arrow annotation is a line with optional arrow heads draw at each end.

The line and arrow heads can be customized.

Examples

The following example creates an arrow annotation on a plot from (0 0) to (100 100) with arrows at both ends. The front head uses a line and the tail head a triangle.

```
shell> gui_create_charts_arrow_annotation -plot $plot -start {0 0} -end
 {100 100} \
  -fhead line -thead triangle
```

---

gui_create_charts_ellipse_annotation

Create ellipse annotation in view or plot

Syntax

```
ellipse_id gui_create_charts_ellipse_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-center position
-rx length
-ry length
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
length           float
name_value_list  string
ellipse_id         annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-center position`

Center of the ellipse.

`-rx length`

X Radius of the ellipse.

Feedback

`-ry` *length*

Y Radius of the ellipse.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

ellipse_id

Returns id of created annotation.

Description

Add an ellipse annotation to plot or view.

The background and border of the ellipse can be customized.

Examples

The following example creates an ellipse annotation on a plot centered at (0 0) with a radius of 60 in x direction and 40 in y direction.

```
shell> gui_create_charts_ellipse_annotation -plot $plot -center {0 0} -rx
 60 -ry 40
```

- gui_get_charts_property

Feedback

gui_create_charts_model

Create a model from data for use in charts

Syntax

```
model_id gui_create_charts_model
{ -csv filename | -clct collection |
-tcl tcl_list }
[ { -comment_header | -first_line_header } ]
[ -first_column_header ]
[ -transpose ]
[ -columns column_names ]
[ -column_type column_type ]
[ -name string ]
```

Data Types

```
filename      string
collection    string
tcl_list      string
column_names  string
column_type   string
```

Arguments

`-csv filename`

Create model from contents of specified csv filename.

A CSV file has comma separated fields.

The *comment_header*, *first_line_header* and *first_column_header* options can be used to determine which (if any) lines are used for horizontal and vertical headers.

`-clct collection`

Create model from contents of a collection. Each row consists of a list of attribute values from the collection object.

The *columns* option can be used to specified which attributes are used to populate the table from the collection. If the *columns* option is not specified then the attributes from the ALL attribute group are used.

`-tcl tcl_list`

Create model from the values in a tcl variable.

The tcl variable must be a list of lists. The data is a list of rows where each row is a list of column values.

Feedback

The *transpose* option can be used to transpose the value array so lists of columns can be specified where each column is a list of row values.

`-comment_header`

Specifies that the first comment (line starting with a #) contains the names of the horizontal column headers.

Only used by the *csv* option.

`-first_line_header`

Specifies that the first line contains the names of the horizontal column headers.

Used by the *csv* and *tcl* options.

`-first_column_header`

Specifies that the first column (first field in each row) contains the names of the vertical row headers.

If the data also has a horizontal header then the first field of the horizontal header is ignored.

Used by the *csv* and *tcl* options.

`-transpose`

Specifies that the tcl value array from *tcl* option is transposed so lists of columns can be specified where each column is a list of row values.

`-columns` *`column_names`*

Specifies a list of names for the attributes to query from the collection to generate the columns of each row.

Used by the *clct* option.

`-column_type` *`column_type`*

Specifies the type and optional formatting of the values in the columns.

If the type of the column is not specified then the application will try to automatically determine it depending on whether the values can be all converted to real or integer values. If not the default string type is used.

The specified value is an ordered list of column type data. Each column type data is a list where the first element specifies the type and any extra elements specify extra name values to customize the type. By default, the type is associated with the column number matching the index of the item but a specific column can be specified by including the column name or number with the type value in the first element.

Feedback

Syntax:

- column_type_data : { <column_type> [<name_values>]}
- column_type : { [<column>] <type> }
- column : column_name|column_index
- type : integer|real|string|...
- name_values : <name_value> <name_value> ...
- name_value : { <name> <value> }

The supported name values are dependant on the column type.

Column types can be queried using:

```
gui_get_charts_data -global -name column_types
```

The column types named values can be queried using:

```
gui_get_charts_data -global -name column_type.names -data $type
```

`-name` *`string`*

Specifies the name of the model.

This can be used to annotate the model so the user can more easily identify what data it contains in the gui.

If the *csv* option is used then the filename is the default name.

Returns

model_id

The id of the created model.

This can be used as input to the *gui_create_charts_plot* command and other commands to do further processing on the model.

Description

This command creates a persistant model and loads data into it so it can be used as the data source for one or more plots.

The command returns a model id which can be used as input to the *gui_create_charts_plot* and other charts commands.

Examples

The following example creates a model from the csv file "test.csv" using the first line for the column headers.

Feedback

```
shell> gui_create_charts_model -csv "test.csv" -first_line_header
```

The following example creates a model from a collection of all shapes with columns for the name and layer attributes.

```
shell> gui_create_charts_model -clct [get_nets] -columns [list name
 layer]
```

See Also

- gui_create_charts_plot

---

gui_create_charts_plot

Create a plot of the type using the supplied data

Syntax

```
plot_name gui_create_charts_plot
-view view_name
{ -clct collection | -model model_id }
-type plot_type
[ -columns column_names ]
[ -title string ]
[ -properties name_value_list ]
[ -xmin float ]
[ -ymin float ]
[ -xmax float ]
[ -ymax float ]
```

Data Types

```
view_name        string
collection       string
model_id         int
plot_type        string
column_names     string
name_value_list  string
```

Arguments

`-view view_name`

Parent view for plot.

`-clct collection`

Collection to use for input data. Each row consists of a list of attribute values from the collection object.

The *columns* option is used to specified which attributes are read from the collection to populate the table values.

Feedback

Note: the resultant model is a snapshot of the specified collection's attribute values and will not updates as the collection is changed.

`-model` *`model_id`*

The model to use for input data.

`-type` *`plot_type`*

The type of plot to display:

The plot types can be queried using the command *gui_get_charts_data -global -name plot_types*

`-columns` *`column_names`*

Specifies the columns to use for each plot column parameter.

The columns string is a command separated list of name value pairs of the form "<parameter name>=<column name>".

The parameter names are plot type dependent.

When the *model* option is specified the column names are column indices (0 based) or column header names.

When the *clct* option is specified the column names are attributes names.

`-title` *`string`*

Specifies the title for the plot.

`-properties` *`name_value_list`*

Specifies a list of name value pairs for the properties to set on the created plot.

`-xmin` *`float`*

User specified minimum x value (to override the auto calculated range).

`-ymin` *`float`*

User specified minimum y value (to override the auto calculated range).

`-xmax` *`float`*

User specified maximum x value (to override the auto calculated range).

`-ymax` *`float`*

User specified maximum y value (to override the auto calculated range).

Returns

plot_name

The id of the created plot.

Feedback

Description

Create plot in a view using values in data model.

The view and model data must be created before the plot can be added.

Examples

The following example creates a distribution plot from the specified model using values from the first column.

```
shell> set window [gui_get_current_window -mru]
shell> set view [gui_create_window -parent $window -type Charts]
shell> gui_create_charts_plot -view $view -model $model -type
 distribution -columns "value=0"
```

See Also

- gui_create_window

---

gui_create_charts_point_annotation

Create point annotation in view or plot

Syntax

```
point_id gui_create_charts_point_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-position position
[ -size length ]
[ -type symbol_type ]
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
length           float
symbol_type      string
name_value_list  string
point_id           annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

Feedback

`-plot` *plot_name*

Plot to add annotation to.

`-id` *string*

Optional identifier string for annotation.

`-tip` *string*

Optional tip string for annotation.

`-position` *position*

Point position.

`-size` *length*

Point size.

`-type` *symbol_type*

Point symbol type.

One of: dot, cross, plus, y, triangle, itriangle, box, diamond, star5, star6, circle, pentagon, ipentagon, hline, vline.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

point_id

Returns id of created point.

Description

Add a point annotation to plot or view.

The background and border of the point can be customized.

Examples

The following example creates a point annotation on a plot with a circle symbol at (0 0).

```
shell> gui_create_charts_point_annotation -plot $plot -position {0 0}
 -type circle
```

---

gui_create_charts_polygon_annotation

Create polygon annotation in view or plot

Syntax

```
poly_id gui_create_charts_polygon_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-points position_list
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position_list    string
name_value_list  string
poly_id            annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

Feedback

`-points` *position_list*

List of polygon points.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

poly_id

Returns id of created polygon.

Description

Add a polygon annotation to plot or view.

The background and border of the polygon can be customized.

Examples

The following example creates a polygon annotation on a plot with a red background with 50% alpha.

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -background 1 -fill_color red -fill_alpha 0.5
```

Feedback

gui_create_charts_polyline_annotation

Create polyline annotation in view or plot

Syntax

```
poly_id gui_create_charts_polyline_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
-points position_list
[ -properties name_value_list ]
```

Data Types

```
view_name         string
plot_name         string
position_list     string
name_value_list   string
poly_id             annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

`-plot plot_name`

Plot to add annotation to.

`-id string`

Optional identifier string for annotation.

`-tip string`

Optional tip string for annotation.

`-points position_list`

List of polygon points.

`-properties name_value_list`

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

poly_id

Returns id of created poly line.

Feedback

Description

Add a multi-point line annotation to plot or view.

The background and border of the line can be customized.

Examples

The following example creates a polyline annotation on a plot with a red border with 50% alpha.

```
shell> gui_create_charts_polygon_annotation -plot $plot \
  -points "{0 0} {10 10} {20 40} {30 20} {40 10} {50 60} {60 40}" \
  -border 1 -stroke_color red -stroke_alpha 0.5
```

---

gui_create_charts_rectangle_annotation

Create rectangle annotation in view or plot

Syntax

```
rect_id gui_create_charts_rectangle_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
[ -rectangle string ]
[ -properties name_value_list ]
```

Feedback

Data Types

```
view_name        string
plot_name        string
name_value_list  string
rect_id            annotation_id
```

Arguments

`-view` *view_name*

Charts View to add annotation to.

`-plot` *plot_name*

Plot to add annotation to.

`-id` *string*

Optional identifier string for annotation.

`-tip` *string*

Optional tip string for annotation.

`-rectangle` *string*

Rectangle bounding box

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

rect_id

Returns id of created rectangle.

Description

Add a rectangle annotation to plot or view.

The background and border of the rectangle can be customized.

Examples

The following example creates a rectangle annotation on a plot from (0 0) to (100 100).

```
shell> gui_create_charts_rectangle_annotation -plot $plot -start {0 0}
 -end {100 100}
```

gui_create_charts_text_annotation

Create text annotation in view or plot

Syntax

```
text_id gui_create_charts_text_annotation
{ -view view_name | -plot plot_name }
[ -id string ]
[ -tip string ]
{ -position position | -rectangle bounding_box }
-text string
[ -properties name_value_list ]
```

Data Types

```
view_name        string
plot_name        string
position         string
bounding_box     string
name_value_list  string
text_id            annotation_id
```

Arguments

`-view view_name`

Charts View to add annotation to.

Feedback

`-plot` *plot_name*

Plot to add annotation to.

`-id` *string*

Optional identifier string for annotation.

`-tip` *string*

Optional tip string for annotation.

`-position` *position*

The position of the text.

`-rectangle` *bounding_box*

The bounding box of the text.

`-text` *string*

The text to display.

`-properties` *name_value_list*

Specifies a list of name value pairs for the properties to set on the created annotation.

Returns

text_id

Returns id of created text.

Description

Add a text annotation to plot or view.

The background, border and font of the text can be customized.

Examples

The following example creates a text annotation on a plot at (0 0) with the text "Test text".

```
shell> gui_create_charts_text_annotation -plot $plot -position {0 0}
 -text "Test text"
```

gui_create_clock_graph

Creates a clock graph.

Syntax

gui_create_clock_graph

```
-clct objects
[-levelized]
[-latency]
```

Arguments

`-clct`

Collection of objects to be used to generate a clock graph.

`-levelized`

Generates a levelized clock graph.

`-latency`

Generates a latency clock graph.

Description

The command generates a levelized or latency clock graph using a selected set of objects.

Examples

The following example generates a levelized clock graph using a collection of clock paths.

```
prompt> gui_create_clock_graph -clct $clock_paths -levelized
```

See Also

- change_selection

Feedback

gui_create_clock_histogram

Create a histogram view for given clocks and corner.

Syntax

status *gui_create_clock_histogram*

```
-clocks clocks
-corner corner
-type type
```

Data Types

```
clocks  collection
corner  collection
type  string
```

Arguments

`-clocks` *clocks*

Specifies the clocks on which the latency histograms are calculated. This is a required option.

`-corner` *corner*

Specifies the corner from which the latency histogram is traced. This is a required option.

`-type` *type*

Specifies the latency histogram type. The option value could be one of "launch" or "capture". This is a required option.

Description

Create a new view to show the latency histogram of specified clocks at specified corner.

Examples

The following example create the launch latency histogram of clock CLK3 with corner cr1.

```
prompt> gui_create_clock_histogram \\
   -clocks [get_clocks CLK3] -corner cr1 \\
   -type launch
```

gui_create_menu

Create a menu item for the toplevel menubar or a context menu item. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item.

Feedback

Syntax

string *gui_create_menu* -menu *HierMenuName*

```
<-tcl_cmd        TclCmd|-separator|-heading headingText|-task taskName>
[-enable_cmd     EnableCmd]
[-get_state_cmd  GetStateCmd]
[-icon           IconFilePath]
[-hot_key        HotKey]
[-tooltip        ToolTip]
[-help_string    HelpStr]
[-anchor_item    AnchorItem]
[-anchor_offset  AnchorOffset]
[-position       MenuPos]
[-window_type    WindowTypeName]
[-root           ContextMenuRoot]
[-reference      RefMenuItem]
[-reference_menu_root RefMenuRoot]

HierMenuName     String
TclCmd           String
EnableCmd        String
GetStateCmd      String
IconFilePath     String
HotKey           String
ToolTip          String
HelpStr          String
AnchorItem       String
AnchorOffset     Integer
MenuPos          Integer
WindowTypeName   String
ContextMenuRoot  String
RefMenuItem      String
RefMenuRoot      String
```

Arguments

`-menu` *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to create. If a level of the hierarchy does not exist in the menu structure it will be created automatically by this command. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so.

`-tcl_cmd` *TclCmd*

TclCmd specifies the tcl command to execute when the menu item is selected. This option is mutually exclusive with the -separator and -heading options.

Feedback

`-separator`

This option creates a menu item separator. It is mutually exclusive with the -tcl_cmd and -heading options.

`-heading` *`headingText`*

This option creates a text heading in the menu with the specified *headingText*. It is visually distinct from actual menu items, and it is not selectable like an actual menu item is. This is used to provide general grouping information without requiring an additional level of sub menu. This option is mutually exclusive with the -separator and -tcl_cmd options.

`-enable_cmd` *`EnableCmd`*

EnableCmd specifies the tcl command to evaluate whether the menu item should be enabled or disabled. The tcl command should return "true" or "1" to enable, and return "false" or "0" to disable. If the enable_cmd is not specified then the menu item will always be enabled.

`-get_state_cmd` *`GetStateCmd`*

GetStateCmd specifies the tcl command that will be executed to determine whether the menu item should be in an on (checked or pushed-in) or off (unchecked or normal) state. Most menu items don't have persistent state, and for those the get_state_cmd should not be specified. This tcl command returns "true" or "1" for the "on" state, and returns "false" or "0" for the "off" state.

`-icon` *`conFilePath`*

IconFilePath specifies the absolute pathname of the icon file. The file should be in *.xpm* format. Typical application-supplied icons are 16x16 pixels in size and use a transparent background (color 'None' in xpm format).

`-hot_key` *`HotKey`*

HotKey specifies the hotkey (accelerator) for the menu item.

`-tooltip` *`ToolTip`*

ToolTip specifies the tooltip for the menu item.

`-help_string` *`HelpStr`*

HelpStr specifies the help string for the menu item. The help string is displayed in the status bar.

`-anchor_item` *`AnchorItem`*

AnchorItem specifies the existing menu item that will be used as the anchor position for this new menu item. This option is used together with the -anchor_offset option to determine the location of the new menu item. The

Feedback

-position option cannot be used along with the -anchor_item and -anchor_offset options.

`-anchor_offset` *`AnchorOffset`*

AnchorOffset specifies the offset from the anchor item position that will be used to determine the location of the new menu item in the menu hierarchy. The offset must be a positive or negative integer, and not zero. If positive, the new menu item will be placed below the anchor item by the specified offset. If negative, it will be placed above the anchor item position by the absolute value of the specified offset. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

`-position` *`MenuPos`*

MenuPos specifies the absolute menu position for the menu item within the parent popup menu. The -position option cannot be used with the -anchor_item and -anchor_offset options.

`-window_type` *`WindowTypeName`*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-root` *`ContextMenuRoot`*

ContextMenuRoot specifies the context menu root to which the menu item being defined will be added. A context menu root groups menu items that share the same context menu root. The context menu root is used for context menu. Context menu, is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

`-reference` *`RefMenuItem`*

RefMenuItem specifies the menu item under the toplevel window's menu bar, which will be used to define the behavior of the menu item being defined. Often used with the -root option to help associate a context menu item with an already defined menu entry under the menu bar. Used with the -window_type option to completely specify the reference menu item under the menu bar. If the -window_type option is not specified, the default toplevel window type as specified with the tcl variable "::gui_default_window_type" will be used.

`-reference_menu_root` *`RefMenuRoot`*

RefMenuRoot specifies the menu root under which the reference menu item is defined. This is used to specify the menu root for the reference menu item when it is not the default menu root for the toplevel window type.

Feedback

`-task` *taskName*

taskName specifies the task name for the menu item. This is used to associate the menu item with a task in the task list.

Description

This command creates a menu item for the menu bar of a top level window. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item. The menu hierarchy separator is denoted by "->".

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default empty value. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_icc_gui.tcl for IC Compiler.

Examples

The following simple example adds a new toplevel popup menu *&Favorite* in the menubar and add a submenu named *Preferences* then add an item named *My &Item* to that submenu. This menu item will be enabled if *enable_my_item* is set to 1 and disabled otherwise. A hotkey and tooltip are also provided.

```
set enable_my_item 1
proc enable_my_item {} {
    if { $::enable_my_item == 1 } {
        return 1
    }
    return 0
}
gui_create_menu -menu "&Favorite->Preferences->My &Item" \\
             -tcl_cmd "echo {executing My Item}" \\
             -enable_cmd "enable_my_item" \\
             -hot_key "Ctrl+N" \\
             -tooltip "short tooltip description for My Item" \\
             -help_string "long status bar description for My Item" \\
             -icon "/syn/sparc/my_item.xpm"
```

The following IC Compiler example illustrates creating a new menu item in the context menu of the layout window which will refer to the Zoom Fit Selection menu item from the Layout window main menu bar. This assumes that the tcl variable "gui_default_window_type" is set to the ICC window type "LayoutWindow" and thus it is not necessary to specify the -window_type option with the value of "LayoutWindow".

Feedback

gui_create_menu -menu "Zoom Fit Selection" \\ -root layout_view_menu_root \\ -reference "View->Zoom->Zoom Fit Selection"

The following example create a new Tcl-based menu entry in the context menu which invokes a procedure # called do_my_thing.

gui_create_menu -menu "Do My Thing" \\ -root layout_view_menu_root \\ -tcl_cmd "do_my_thing"

The following IC Compiler example illustrates adding a context menu item to the path schematic context menu which refers to a menu item in the Main window. This example assumes that there is a context menu root called "path_schematic_contextmenu_root", a hierarchical menu item in the toplevel menu bar of the window type "MainWindow" with the hierarchical menu name "Schematic->Delete Selected".

gui_create_menu -menu "Remove Selected" \\ -root path_schematic_contextmenu_root \\ -reference "Schematic->Delete Selected" -window_type MainWindow

---

gui_create_message_waiver

Creates an EMS message waiver to waive matching messages in Message Browser.

Syntax

```
status gui_create_message_waiver
-name waiver_name
[-rule EMS_check_rule_name]
[-domain EMS_domain_name]
```

Feedback

```
[-comment comment_string]
-filter filter_list
```

Data Types

```
waiver_name          string
EMS_check_rule_name string
EMS_domain_name      string
comment_string       string
filter_list          list
```

Arguments

`-name waiver_name`

Specifies the name of the waiver to create.

`-rule EMS_check_rule_name`

Specifies the name of EMS check rule whose error or warning messages will be matched against the filter. If not specified, the filter is applied to messages generated by all rules of a given domain, or on all messages of currently opened database, if no domain is specified. The default is empty.

`-domain EMS_domain_name`

Specifies the name of EMS domain whose error/warning messages will be matched against the filter. If not specified, the filter is applied to all messages of currently opened database. The default is empty.

`-comment comment_string`

Specifies the comments or notes to the waiver.

`-filter filter_list`

Specifies list of criteria for the filter. The criteria should contain column name, a match value, and match operation in list format {COULMN_NAME MATCH_OP MATCH_VALUE}. The column name should be exactly the same as visible param title defined in the EMS database for related checks, or the column name in message list of Message Browser. Each of matched values will be converted to predefined EMS type for comparison, such as string, int, float, and so on. The possible matching operations are '==', '=~'(match), '<', '<=', '>', '>=' applied to suitable types. A filter can contain multiple criteria for different column fields. A messages is waived only when all criteria within this option are matched. This is a required option.

Description

The *gui_create_message_waiver* command creates a waiver with the filter list. The waiver is used to waive the matching EMS message from the Message Browser. The tool tests the messages against the filter strings defined in the waiver. When a string matches the

Feedback

criteria, the message status is set to 'waived'. If 'hide waived' preference is enabled, the waived messages are hidden from the message browser.

Examples

The following command creates waiver which will filter message generated by rule 'CTS_QOR_002' based on the filter list:

```
prompt> gui_create_message_waiver -name waiver_2 -rule CTS_QOR-002 \\
   -filter { { Num <= 20 } { { Net Name } == gclk } { Capacitance ==
 0.45 } }
```

See Also

---

gui_create_pref_category

Create a preference category.

Syntax

string *gui_create_pref_category* -category *Category*

```
Category        String
```

Arguments

`-category` *Category*

Category specifies the category to create.

Description

This command creates a preference service category with the specified name, which can be used to store and categorize key-value pairs that are created with the *gui_create_pref_key* command. If successful, the command returns the name of the category that is created.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
```

Feedback

---

gui_create_pref_key

Create a preference key.

Syntax

string *gui_create_pref_key* -key *Key*

```
-value_type ValueType
-value Value
[-category Category]
[-keep_value_if_exist]
[-read_only]
[-description Description]
[-min Minimum_Value]
[-max Maximum_Value]
[-legal_value_list Value_List]
[-string_to_int_map Value_Map]
[-save_on_exit Boolean_Value]

Key             String
Category        String
ValueType       one of [bool|integer|double|color|string|rect|point|size]
Value           Depends on the value type
Description     String
Minimum_value   Minimum integer or double value
Maximum_value   Maximum integer or double value
Value_List      String List
```

Feedback

```
Value_Map       A list of string pair lists, each mapping a string value
 to an integer value.
Boolean_Value   true | false
```

Arguments

`-key` *Key*

Key specifies the name of the key to create.

`-value_type` *ValueType*

ValueType specifies the data type of the value of the key. It must be one of [bool | integer | double | color | string].

`-value` *Value*

Value specifies the value of the key. The value should be set appropriately in accordance with its value type. The *bool* type accepts [true, false, 0, 1, on, off]. The *color* type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

`-category` *Category*

Category specifies the category that the key belongs to. If not specified, a default category will be assigned.

`-keep_value_if_exist`

This Boolean option specifies to keep current value if the key already exists. The default is that the key will be assigned the value given in the *-value* option.

`-read_only`

If given, this flag specifies that the preference key value is read-only and its value cannot be set after the key has been created.

`-description` *Description*

If given, the given description string with the meaning of the key is assigned to the preference key.

`-min` *Minimum_Value*

If given, specifies the minimum value for an integer or double type preference key.

`-max` *Maximum_Value*

If given, specifies the maximum value for an integer or double type preference key.

Feedback

`-legal_value_list` *`Value_List`*

If given, this option specifies discrete valid values for an iteger, double or string type preference key. Input the argument using Tcl list syntax: {{prefVal} ...}

`-string_to_int_map` *`Value_Map`*

If given, provides a map from a string key value to an integer value for preferences of integer type. Input the argument as a Tcl list of Tcl list where the internal list is a pair of the string value and the integer value: {{stringval intval} ...}

`-save_on_exit` *`Boolean_Value`*

If given, specifies whether the preference key value is saved to the user preference file upon existing the application. Acceptable argument is either *true* or *false*.

Description

This command creates a preference key with the specified key name. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to the default category. Returns the value of the preference key.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type
 integer -value 200
```

---

gui_create_schematic

Creates a schematic view.

Syntax

string *gui_create_schematic*

```
[-clct objects]
[-size {w h}]
[-be_specific bool]
```

Data Types

```
objects  collection
{w h}    string
```

Arguments

`-clct objects`

Generates a schematic for the specified object collection. The current selection is used if not specified.

`-size {w h}`

Generates a schematic for the specified width (w) and height (h). Application default view size is used if not specified.

`-be_specific bool`

Controls the behavior of the schematic generation as to whether additional objects beyond those specifed using -clct. If not specifed, or specifed as false, additional objects will be included in the new schematic to provide connectivity and context. If specified as true, only the objects specified will be included in the new schematic.

Description

The command generates a new schematic view from the current selection or an object collection if specified.

Examples

The following example generates a schematic view of the hierarchical cell named RAM_1.

```
prompt> gui_create_schematic -clct [find cell RAM_1]
```

Feedback

See Also

- change_selection

---

gui_create_task

Create a task.

Syntax

gui_create_task

```
-task          TaskName
-item_root     ItemRootName
[-default]

TaskName          String
ItemRootName      String
```

Arguments

`-task` *TaskName*

TaskName specifies the name of the new task. Task name must be unqiue.

`-item_root` *ItemRootName*

ItemRootName specifies the name of the task root that will be associated with the task. Item root names are unique. If the same item root is associated with multiple tasks, then the tasks share the same item root.

`-default`

This option specifies that this command will be the default task set as the current task. If another task is later created with this option, the the later setting overrides any previous settings.

Description

This command creates a task. A task defines the user task context for the whole application. Tasks may be used to configure menus and also to present a hierarchical list of task items to the user to navigate in the Task Assistant. The hierarhical list of task items is defined with the gui_create_task_item command.

Examples

The following simple example creates a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -task MyAppTask -item_root MyAppTaskRoot
```

Feedback

```
gui_create_task_page -name InputFormPage -format tk -source
 create_widget_proc
gui_create_task_page -name AppDocument -format html
 -source ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask
 -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask
 -page AppDocument
```

See Also

- gui_create_task_item
- gui_create_task_page

---

gui_create_task_item

Create an item in the task tree to access in the Task Assistant.

Syntax

gui_create_task_item

```
-name           ItemName
<-task TaskName | -item_root ItemRootName>
-page           PageName
[-search_terms  TermsList]

ItemName          String
TaskName          String
ItemRootName      String
PageName          String
TermsList         List
```

Arguments

`-name` *ItemName*

ItemName specifies the hierarchical name given to the task item being created. This is also the text displayed to the user in the Task Assistant.

`-task` *TaskName*

TaskName specifies the task in which this task item is created. If a task name is used to create the task item, the item is inserted into the task item root associated with the task in the create_task command. If other tasks use the same item root, they will also see the new task item created with this command. This option is mutually exclusive with the -item_root option. One must be specified but not both.

Feedback

`-item_root` *`ItemRootName`*

ItemRootName specifies the task item root in which this task item is created. Item root names are associated with task names with the gui_create_task command and allows multiple tasks to share a single task item root. This option is mutually exclusive with the -item_root option. One must be specified but not both.

`-page` *`PageName`*

PageName specifies the page content factory associated with this task item. When the user selects the task item, the page specified by this option will be constructed and shown in the Task Assistant.

`-search_terms` *`TermsList`*

TermsList specifies additional terms that can be matched by the command search feature to find this task item. For example, if the task page allows the user to specify values for input parameters to a command, you may want to associate the name of that command as additional search term for the task item.

Description

This command creates a task item in the given task. Task items are defined in a hierarchy with hierarchy levels delimited by the separator string "->". The hierarchy of task items are shown in the task item navigation tree in the Task Assistant.

When the user selects a leaf item in the task navigation tree, the Task Assistant will show the task page associated with the item by this command. Currently, the pages can either be constructed from an HTML document or from a Tk widget factory.

Examples

The following simple example adds a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot

gui_create_task_page -name InputFormPage -format tk -source
 create_widget_proc
gui_create_task_page -name AppDocument -format html
 -source ./MyAppDocument.html

gui_create_task_item -name "Application->Input Form" -task MyAppTask
 -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask
 -page AppDocument
```

Feedback

See Also

- gui_create_task
- gui_create_task_page

---

gui_create_task_page

Creates a task page with Command Form, HTML content or Tk Command Form.

Syntax

gui_create_task_page

```
-name taskPageName
-format pageType
-source contentSource
```

Data Types

taskPageName string

pageType string

contentSource string

Arguments

`-name` *taskPageName*

taskPageName specifies the name of a new task page.

`-format` *pageType*

Define this new page as a specified Type Page. *pageType* can be command, html, tk or tab. Which specifies the Command Form Page, HTML Page, Tk Command Form Page or Tabs Page.

`-source` *contentSource*

Define the content to be shown in this page. If this page is a Command Form Page or a Tk Command Form Page, *contentSource* is the command name. If it is a HTML Page, *contentSource* specifies the full path to the file with HTML source for the task page. If it is a Tabs Page, *contentSource* specifies a list of existing page names or page&title pairs.

Description

The *gui_create_task_page* command creates several kinds of task pages which can be shown in the task assistant. The name option value is the unique name of the page. The format option defines which kind of page to be created and the source option defines what content to be shown in the task page.

Feedback

Examples

The following simple example creates three new task pages, then show them in the task assistant.

```
prompt> gui_create_task_page -name page1 -format command -source
 gui_report_map
prompt> gui_create_task_page -name page2 -format html
 -source ./MyAppDocument.html
prompt> proc create_widget_proc {widgetName parentName} {
          p#populate $wigetName with Tk
        p}
prompt> gui_create_task_page -name page3 -format tk -source
 create_widget_proc
prompt> gui_create_task_page -name page4 -format tab -source {page1 page2
 {page3 title} }
prompt> gui_create_task -task "Testing Task" -item_root
 test_task_item_root
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 1"
 -page page1
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 2"
 -page page2
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 3"
 -page page3
prompt> gui_create_task_item -task "Testing Task" -name "Testing Page 4"
 -page page4
prompt> gui_show_task -task "Testing Task:Testing Page"
```

- gui_create_task
- gui_create_task_item

---

gui_create_tk_palette_type

Create a type of Tk palette.

Syntax

```
status gui_create_tk_palette_type
-type string
-title string
[ -icon string ]
-window_types string_list
[ -dock_edge dock_edge ]
-create_command string
```

Feedback

Data Types

dock_edge string

Arguments

-type *string*

Unique palette type name for the palette.

The type name must be non-empty, must start with a letter or underscore, and must only contain letter, number or underscore characters.

-title *string*

Title string for the palette.

-icon *string*

Icon to display for the palette.

-window_types *string_list*

List of window types which the palette is to be added to.

-dock_edge *dock_edge*

The default edge to add the palette

left - dock on left edge
right - dock on right edge
top - dock on top edge
bottom - dock on bottom edge

-create_command *string*

The option specifies the tcl command to be run when the palette is created so that the palette's tk widget can be populated with tk child widgets and any other initialization can be performed.

The tcl procedure takes two arguments 'windowName' and 'parentName' where 'windowName' is the tk palette widget to populate and 'parentName' is the name of the parent window.

Description

Creates a user defined tk palette when a window of any of the specified types is created.

Examples

The following example creates a palette of type 'mypalette', with a title of 'My Palette' which calls the 'build_my_palette' tcl procedure to populate the palette with tk widgets whenever a new window of type 'LayoutWindow' is created.

The 'build_my_palette' creates a text entry filed in a frame for the palette.

Feedback

```
shell> proc build_my_palette {windowName parentName} {
   set top_frame [frame $windowName.frame]
   pack $top_frame -fill both -expand 1
   set entry [entry $top_frame.entry -textvariable $::var]
   pack $entry
 }
shell> gui_create_tk_palette_type -type mypalette -title "My Palette" \\
  -create_command build_my_palette -window_types "LayoutWindow"
 -dock_edge right
```

---

gui_create_tk_view_type

Create a type of Tk view.

Syntax

string *gui_create_tk_view_type* -type *string*

-create_command *tclCommandString*

```
string string
string tclCommandString
```

Arguments

`-type string`

Specifies the type of Tk view to create.

`-create_command tclCommandString`

Specifies the Tcl command string to execute when creating the view.

Description

The *gui_create_tk_view_type* command is used to create a new type of Tk view in the GUI framework. It takes a type string and a Tcl command string as arguments. The type string specifies the kind of view to create, while the command string defines the actions to be performed when the view is created.

Examples

To create a new Tk view of type "example_view", you would use the following command:

```
string gui_create_tk_view_type -type "example_view" -create_command
 "example_view_create_command"
```

See Also

- gui_create_tk_palette_type

Feedback

gui_create_toolbar

Create a toolbar with the specified name.

Syntax

string *gui_create_toolbar* -name *ToolBarName*

```
[-title       Title]
[-dock_side   DockSide]
[-hidden]
[-window_type WindowTypeName]

ToolBarName     String
Title           String
DockSide        String
WindowTypeName  String
```

Arguments

`-name ToolBarName`

ToolBarName is the toolbar identifier for the new toolbar.

`-title Title`

Title specifies the title or caption of the toolbar.

`-dock_side DockSide`

DockSide specifies the side of the window the tool docks to by default. The legal values are top, bottom, left, right.

`-hidden`

-hidden specifies the toolbar should be hidden by default.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command creates a toolbar with the given name and title. Returns the name of the toolbar created.

Examples

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

Feedback

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

See Also

- gui_delete_menu
- gui_delete_toolbar
- gui_create_toolbar_item
- gui_delete_toolbar_item
- gui_get_toolbar_names
- gui_default_window_type
- gui_custom_setup_files

---

gui_create_toolbar_item

Create a button in the specified toolbar.

Syntax

string *gui_create_toolbar_item* -toolbar *ToolBarName*

```
<-menu MenuName|-separator SeparatorName>
[-window_type WindowTypeName]
[-dropdown_menu MenuName]
[-dropdown_icon IconName]

ToolBarName     String
MenuName        String
SeparatorName   String
WindowTypeName  String
IconName        String
```

Arguments

`-toolbar ToolBarName`

ToolBarName specifies the toolbar that the new toolbar item will be added to.

Feedback

`-menu` *`MenuName`*

MenuName specifies the name of the menu item to be invoked from this toolbar button. The "name" of a menu is a string whcih specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -separator option.

`-separator` *`SeparatorName`*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -menu option.

`-window_type` *`WindowTypeName`*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-dropdown_menu` *`MenuName`*

MenuName specifies the associated menu to add as a dropdown menu for the item.

`-dropdown_icon` *`IconName`*

IconName specifies the icon to display on the dropdown menu button.

If not specified a standard menu will be used.

Description

This command adds a toolbar button to the specified toolbar using information described in the -menu option. The -menu option specifies the hierarchical menu name for some menu item. Thus, the toolbar icon becomes another interface for a menu item. Returns the item name if successful.

Examples

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

Create a drop down menu button that has actions that run a command

```
gui_create_menu -menu "Item 1" -tcl_cmd "echo 1" -root "my_root"
gui_create_menu -menu "Item 2" -tcl_cmd "echo 2" -root "my_root"
gui_create_toolbar -name "MyToolbar" -title "My Toolbar" -dock_side top
```

Feedback

```
gui_create_toolbar_item -toolbar MyToolbar -menu "Item 1" \
  -dropdown_menu "my_root" -dropdown_icon my_icon
```

---

gui_create_user_editor_toolbox_type

Create type for editor toolbox user widgets

Syntax

```
status gui_create_user_editor_toolbox_type
-window string
-command string
```

Arguments

`-window string`

Specifies the optional window to initialize the toolbar in.

This allows the user to update toolbar in a single window rather than all windows.

`-command string`

Specifies the command to run to initialize the toolbar.

Feedback

Description

This command defines a type which will be used to populate the user widget area of the editor toolbox palette in the block window. The supplied tcl proc will be run when the toolbar is created or updated in the associated view.

Examples

The following example will create user widgets in the editor boolbox.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_edit_widgets { args } {
shell>   gui_create_user_widget_group -name stamp -type stamp {
shell>     set button [gui_create_user_widget_item -name button -type
 button]
shell>     set_attribute $button label "Button"
shell>     set_attribute $button activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_user_editor_toolbox_type command init_my_edit_widgets
shell> set window [gui_create_window -type BlockWindow]
shell> gui_show_palette -parent $window -type editor_toolbox_palette
```

See Also

- gui_create_user_widget_group
- gui_create_user_widget_item
- gui_create_window
- gui_show_palette
- get_attribute
- set_attribute

---

gui_create_user_widget_group

Create group in user dialog

Syntax

```
status gui_create_user_widget_group
[ -parent string ]
-type string
-name string
[ -label string ]
[ -icon string ]
[ -row string ]
[ -column string ]
```

Feedback

```
[ -layout string ]
[ body ]
```

Arguments

`-parent string`

Specifies the optional parent container or group.

If the command is nested inside another gui_create_user_widget_group command then the parent group is inherited from the parent group.

If the command is not nested, and is run from an initialization tcl command or callback tcl command, then the parent is defaulted to the associated container.

`-type string`

Specifies the group type.

If the string '?' is specified for the type, the command will return a list of allowed types.

`-name string`

Specifies the unique name for the group.

Note: The command will fail if the name has already been used in the container.

`-label string`

Specifies the optional label for the group.

`-icon string`

Specifies the optional icon for the group.

`-row string`

Specifies the row and optional row span for the group if it is added to a grid layout.

The value is a list of one or two values, if one value it specifies the row only, if two values is specified the row and row span.

`-column string`

Specifies the column and optional column span for the group if it is added to a grid layout.

The value is a list of one or two values, if one value it specifies the column only, if two values is specified the column and column span.

`-layout string`

Specifies the layout for the group.

Feedback

If the string '?' is specified for the layout, the command will return a list of allowed layouts.

body

Specifies the commands used to add widgets or other groups inside this group.

Description

This command adds a new user group to the specified parent container or group.

Examples

The following example will create buttons, in a flow group, in the window toolbar container for subsequent Charts views. The buttonPressed callback is called when any button is clicked.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   gui_create_user_widget_group -name buttons -type flow {
shell>     set button1 [gui_create_user_widget_item -window $window -name
 button1 -type button]
shell>     set button2 [gui_create_user_widget_item -window $window -name
 button2 -type button]
shell>     set_attribute $button1 label "Button 1"
shell>     set_attribute $button2 label "Button 2"
shell>     set_attribute $button1 activated_proc buttonPressed
shell>     set_attribute $button2 activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type $gui_default_window_type]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

Feedback

gui_create_user_widget_item

Create item in user widget container

Syntax

```
status gui_create_user_widget_item
[ -parent string ]
-type string
-name string
[ -label string ]
[ -icon string ]
[ -row string ]
[ -column string ]
```

Arguments

`-parent string`

Specifies the optional parent container or group.

If the command is nested inside another gui_create_user_widget_group command then the parent group is inherited from the parent group.

If the command is not nested, and is run from an initialization tcl command or callback tcl command, then the parent is defaulted to the associated container.

`-type string`

Specifies the item type.

If the string '?' is specified for the type, the command will return a list of allowed types.

`-name string`

Specifies the unique name for the item.

Note: The command will fail if the name has already been used in a dialog.

`-label string`

Specifies the label for the control if it is added to a form layout or the optional label to be applied to the control after creation.

Note: If item is added to form layout the label will *only* used for the name of the auto generated widget label.

`-icon string`

Specifies the optional icon to be applied to the control after creation.

Feedback

`-row` *string*

Specifies the row and optional row span for the control if it is added to a grid layout.

The value is a list or one or two values, if one value it specifies the row only, if two values is specified the row and row span.

`-column` *string*

Specifies the column and optional column span for the control if it is added to a grid layout.

The value is a list or one or two values, if one value it specifies the column only, if two values is specified the column and column span.

Description

This command adds a new user item to the specified parent container or group.

Examples

The following example will create buttons, in a flow group, in the window toolbar container for subsequent Charts views. The buttonPressed callback is called when any button is clicked.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   gui_create_user_widget_group -name buttons -type flow {
shell>     set button1 [gui_create_user_widget_item -window $window -name
 button1 -type button]
shell>     set button2 [gui_create_user_widget_item -window $window -name
 button2 -type button]
shell>     set_attribute $button1 label "Button 1"
shell>     set_attribute $button2 label "Button 2"
shell>     set_attribute $button1 activated_proc buttonPressed
shell>     set_attribute $button2 activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\·
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type $gui_default_window_type]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

---

gui_create_utable

Create a new UserTable.

Syntax

string *gui_create_utable*

```
-name              Table_Name
-parent            Table_Name
-columns           Column_List
-timing_path       Tim_Clct
[-expr_columns     Column_Expr_List]
[-meta_obj         MetaObj_Name]
[-replace]
[-fixed_name]

Table_Name         String
Column_List        List of Strings
Column_Expr_List   A list of column-expression pairs
Tim_Clct           Timing Path Collection
MetaObj_Name       String
```

Arguments

`-name` *Table_Name*

The name of the user table to create.

`-parent` *Table_Name*

The name of the parent table that is related to this user table.

`-columns` *Column_List*

A TCL list of column names for the table with optional data type Xpostfix information.

`-expr_columns` *Column_Expr_List*

This allows you to create an expression that fills a table column with the result of that expression. The option is a list of column-expr pairs. Thus the list must have an even number of elements where the odd elements are the column names and the even number elements are the associated expression.The expression can reference other column values by surounding the column name in the

Feedback

following syntax: @{...}. The expression itself can include operators like '+','-','/' and '*' and parentheses. See the example below and see *gui_append_utable* for more info.

`-timing_path` *`Tim_Clct`*

Create and fill a Timing Point Table with the given Timing Path Collection. This is exclusive with the -columns option.

`-meta_obj` *`MetaObj_Name`*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-replace`

If a table already exists with that name, replace it.

`-fixed_name`

Mark the table name as 'fixed' so that it can not be changed in the GUI.

Description

```
This command creates a new user table with the given list of column
 names.
In addition, column names can have postfixes that describe the data type
 of that column.
Or one can use a MetaData object to define the column data types.

Important: This command returns the actual table name created which might
be different if the given table name had bad characters or already
 exists.
So, capture the return value and use it in future calls to this table.

Supported column name postfixes are:

  :string
  :int
  :double
  :cell
  :net
  :port
  :pin
  :point
  :endpoint
  :file
```

Examples

```
The following example creates a new UserTable with the given list of
 columns. The last
```

Feedback

```
three columns also have some data type postfixes. Also note that the
 return value of
the create is captured since the name could be altered if it contained
 illegal chars.
This captured name is then used in following commands like the append
 command.
This example also adds an empty column at the end which is then filled
 with an
expression that references other columns.

set tableName [gui_create_utable -name MyTable -replace \\
                    -columns {
                      full_name
                      arrival:double
                      delay:double
                      {Expr Col:double}
                    } \\
                    -expr_columns {
                      {Expr Col} { 100 * (@{arrival} + @{delay}) }
                    }
               ]

# Append a TCL row: (note: that expr column is empty: {} )
gui_append_utable -name $tableName -rows { {my/path 2.2 3.3 {} } }
```

Feedback

gui_create_vm

Creates a new visual mode container for visual mode buckets. The buckets contain coloring attributes for a collections of design objects.

Syntax

string *gui_create_vm*

```
-name identifier
[-update_cmd update_command]
[-title label]
[-help_topic subject]
[-infotip infotip]
[-discrete  true | false]
[-icon string]
[-netfilter string]
[-float bool]
[-top_exaggeration float]
[-mid_exaggeration float]
[-bot_exaggeration float]
[-show_only_pins_of_nets bool]
[-enable_bucket_delete bool]
```

Data Types

```
identifier          string
update_command      string
label               string
subject             string
infotip             string
net_filter          string
icon_spec           string
```

Arguments

`-name identifier`

Specifies the name that identifies the visual mode. Use this name when another visual mode command requires a visual mode name.

`-update_cmd update_command`

Specifies a Tcl command to execute when the visual mode is accessed. Use this option to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-title label`

Specifies an optional title that is used to label the visual mode in the GUI. The *label* string can contain space characters. By default, the title is the empty string, and the *-name* option value is used to provide the label.

Feedback

`-help_topic` *subject*

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

`-infotip` *infotip*

Specifies the infoTip text string.

`-discrete true | false`

Specifies an optional true or false string indicating whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. By default, visual modes are discrete.

`-icon` *string*

Specifies the icon file. The file contains an icon image for the GUI menus.

`-netfilter` *string*

Specifies the net connection filtering.

`-float true | false`

Specifies whether the bucket contents have a floating point range. By default, this option is false.

`-top_exaggeration` *float*

Specifies the exaggeration for the top bucket. The value should be greater than or equal to zero. By default, the value is 0.

`-mid_exaggeration` *float*

Specifies the exaggeration for the middle bucket. The value should be greater than or equal to -1. By default, the value is -1.

`-bot_exaggeration` *float*

Specifies the exaggeration for the bottom bucket. The value should be greater than or equal to zero. By default, the value is 0.

`-show_only_pins_of_nets true | false`

Specifies whether the layout shows pins of net objects in buckets. By default, the value is false.

`-enable_bucket_delete true | false`

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

Feedback

Description

The *gui_create_vm* command creates an instance of a visual mode. The visual mode provides a container for visual mode buckets, which associate coloring attributes with collections of design objects.

If the -update_cmd that you specify needs input from the user, then you can define the arguments to your procedure with define_proc_attributes, and then use the gui_show_command_form command for your procedure as the -update_cmd. This will show a form that will prompt for the arguments to your procedure and then it will call your proc to update the visual mode using those values. See the man pages for gui_show_command_form and define_proc_attributes for additional details.

Examples

The following example creates a new visual mode named mycoloring1 with the GUI label "Cells Colored By X":

```
prompt> gui_create_vm -name mycoloring1 -title {Cells Colored By X}
```

- define_proc_attributes

---

gui_create_vm_objects

Create objects to hold annotations in visual modes

Syntax

string *gui_create_vm_objects <clct>*

```
string <clct>
```

Feedback

Arguments

<clct>

Objects to convert.

Description

Layout visual modes are used to color objects in the layout given certain criteria. Sometimes you want not only object coloring but some additional annotations displayed with the objects in a bucket.

In order to create this type of visual mode, you need special type of object that can hold annotations. Use this command to create these special objects.

Objects of this type support name and core_obj attribute. The core_obj attribute returns the object that was used to create this object.

Examples

shell> *set objs [gui_create_vm_objects $cells]*

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_update_vm_annotations

---

gui_create_vmbucket

Create new Visual Mode Bucket

Syntax

string *gui_create_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip *infotip*] [-netfilter *net_filter*] [-color *color*] [-pattern *pattern*] [-exaggeration double] [-number int] [-maxval double] [-minval double] [-visible *visibility*] [-title *label*] [-collection *handle*] [-above *bucket_identifier* | -below *bucket_identifier* -at *top*| *bottom*]

```
string mode_identifier
string bucket_identifier
string infotip
string net_filter
string color
string pattern
string visibility
string label
```

Feedback

```
string handle
string bucket_identifier
string bucket_identifier
string top|bottom
```

Arguments

`-vmname` *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name` *bucket_identifier*

Specifies the name by which the visual mode bucket will be identified. It is used as the argument when associated visual mode commands require a visual mode bucket name to be specified.

`-infotip` *infotip*

String for infotip.

`-netfilter` *net_filter*

Specifies net connection filtering.

`-color` *color*

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

`-pattern` *pattern*

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

`-exaggeration double`

Specifies bucket min pixel exaggeration value >= 0.

`-number int`

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

`-maxval double`

Specifies bucket maximum value.

Feedback

`-minval double`

Specifies bucket minimum value.

`-visible` *`visibility`*

Specifies initial visibility of bucket. Valid values are TRUE and FALSE.

`-title` *`label`*

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

`-collection` *`handle`*

Tcl object collection to be colored by this visual mode bucket.

`-above` *`bucket_identifier`*

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

`-below` *`bucket_identifier`*

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

`-at` *`top|bottom`*

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

Description

The gui_create_vmbucket command creates an instance of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The visual mode bucket can be assigned coloring styles and a collection of design objects to which the coloring will be applied when they are rendered as a part of the visual mode.

Examples

Create a visual mode with two buckets, one whose objects will be colored red, and another whose objects will be colored blue:

shell> *gui_create_vm -name foo1 -title "My Visual Mode"*

shell> *gui_create_vmbucket -vmname foo1 -name red -title "Red" -color red*

shell> *gui_create_vmbucket -vmname foo1 -name blue -title "Blue" -color blue -below red*

- gui_update_vm

---

gui_create_window

Creates a window of the specified window type.

Syntax

```
string gui_create_window
-type window_type
[ -parent parent_window_id ]
[ -show_state window_state ]
[ -title title ]
[ -rect rect | -size {width height} ]
[ -icon icon ]
```

Data Types

```
window_type          string
parent_window_id     string
window_state         string
title                string
rect                 rectangle
width                integer
height               integer
icon                 string
```

Arguments

`-type window_type`

Specifies the type of window you are creating. The tool creates an instance of this window type.

Feedback

You can display a list of the supported window types by using the *gui_get_window_types* command.

`-parent` *parent_window_id*

Specifies the window ID of the parent top-level window for the view window you are creating.

If you do not specify a window ID and the window type is not a top-level window type, the tool uses the current top-level window. If there is no current top-level window, the tool creates a new top-level window automatically to host the window you are creating.

`-show_state` *create_window_state*

Specifies the window state in which to display the window you are creating. The result varies depending on whether the window is a top-level window or a view window.

For a top-level window, you can specify one of the following states:

```
maximized -- show maximized (fill whole screen)
minimized -- show iconified
normal    -- show at preferred size
```

Note that the window manager might not fully honor the specified state. See your window manager documentation for more details.

For a view window, you can specify one of the following states:

```
maximized -- show maximized in view area and raise to top
minimized -- show iconified in view area
normal    -- show at preferred size in view area and raise to top
```

If you display a view window in its maximized state, the tool also maximizes any existing view windows. If you display a view window in its minimized or normal state, the tool changes any maximized view windows to their normal states.

The default is -show_state normal.

`-title` *title*

Specifies the title for the top-level or view window you are creating.

Note that the window manager might not fully honor the specified top-level window title string. See your window manager documentation for more details.

`-rect` *rect*

Specifies the size and position of the window in the following format:

```
{{x1 y1} {x2 y2}}
```

Feedback

The coordinates {*x1 y1*} specify the location of the top-left corner, and the coordinates {*x2 y2*} specify the location of the bottom-right corner. These coordinates are relative to the top-left corner of the screen, for a top-level window, or to the top-right corner of the view area in the parent top-level window, for a view window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The *-rect* option and the *-size* option are mutually exclusive.

`-size {`*`width height`*`}`

Specifies the width and height of the window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The *-size* option and the *-rect* option are mutually exclusive.

`-icon` *`icon`*

Specifies the image to be used for the top-level or view window icon.

For a view window, the icon appears in the top-left corner of the title bar when the window is in its normal or minimized state and at the left side of the menu bar when the window is maximized.

For a top-level window, the icon might not be displayed when the window is in its normal, minimized, or maximized state. See your window manager documentation for more details.

Description

This command creates a window of the specified type and returns the window ID. The window type that you specify controls whether the window is a top-level window or a view window.

Examples

The following example creates a top-level layout window and a minimized layout view window.

```
prompt> set top [gui_create_window -type LayoutWindow]
LayoutWindow.1
prompt> gui_create_window -type Layout -parent $top \\
   -show_state minimized
layout.1
```

---

gui_create_window_toolbar_type

Create new type for view toolbar

Syntax

```
status gui_create_window_toolbar_type
-type string
[ -name string ]
[ -icon string ]
-view_types string_list
-command string
[ -apply ]
```

Arguments

`-type string`

Specifies the toolbar type.

The toolbar type must be unique.

`-name string`

Specifies the user visible name for the toolbar.

If not specified then the type name is used.

`-icon string`

Specifies the optional icon for the toolbar.

`-view_types string_list`

Specifies the window view types which the toolbar can be added to.

Feedback

`-command` *string*

Specifies the command to run to initialize the toolbar.

`-apply`

Specifies that the type will be applied to existing views.

Description

This command defines a new toolbar type which will be populated using the user supplied tcl proc when the toolbar is created in the associated view.

Examples

The following example will create a user toolbar in the Charts view with a button.

```
shell> proc buttonPressed { args } { echo "Button Pressed" }
shell> proc init_my_toolbar { args } {
shell>   gui_create_user_widget_group -name stamp -type stamp {
shell>     set button [gui_create_user_widget_item -name button -type
 button]
shell>     set_attribute $button label "Button"
shell>     set_attribute $button activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

See Also

---

gui_define_charts_proc

Define tcl command to use in charts expression evaluation

Feedback

Syntax

```
status gui_define_charts_proc
name
args
body
```

Arguments

name

Name of the procedure.

The procedure name must be non-empty, start with an underscore or a letter and contain only underscore or letter characters.

args

The arguments of the procedure.

body

The body of the procedure.

Description

Define custom tcl command to use in charts expression evaluation.

The syntax and arguments are the same as the standard tcl *proc* command.

If the arguments and body strings are empty then any existing procedure of that name is deleted.

To list all the defined charts procedures you can use the command:

```
shell> gui_get_charts_data -global -name procs
```

To get the args and body for an existing procedure you can use the command:

```
shell> gui_get_charts_data -global -name proc_data -data <proc_name>
```

Examples

The following example changes a model to create a new column with the square root of values in the first column.

```
shell> gui_define_charts_proc test_proc { arg } { return [expr
 {$arg/2.0}] }
shell> gui_change_charts_model -model $model -add -expr
 "test_proc(column(0))" -type real
```

Feedback

See Also

- gui_change_charts_model
- gui_get_charts_data

---

gui_delete_attrgroup

Removes a group of attributes or all attribute groups for an object type.

Syntax

```
status gui_delete_attrgroup
-class design_object
-name name
[-all]
[-quiet]
```

Data Types

```
design_object      string
name               string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the name of the attribute group to be removed for the specified object type.

`-all`

Removes all attribute groups defined for the specified object type.

`-quiet`

Keep quiet and don't print any messages if command was not successfull.

Description

The *gui_delete_attrgroup* command removes the specified attribute group or all attribute groups for the specified object type.

Examples

```
prompt> gui_delete_attrgroup -class Cell -name "Hierarchy"
```

```
prompt> gui_delete_attrgroup -class Cell -all
```

Feedback

See Also

- gui_create_attrgroup
- gui_list_attrgroups
- gui_update_attrgroup

---

gui_delete_menu

Delete a menu item for the toplevel menubar or a context menu

Syntax

string *gui_delete_menu*

```
[-menu HierMenuName | -all]
[-window_type WindowTypeName | -root ContextMenuRoot]

HierMenuName    String
WindowTypeName  String
ContextMenuRoot String
```

Arguments

`-menu HierMenuName`

HierMenuName specifies the hierarchical menu name of the menu item to be deleted. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -all option.

`-all`

This option flag specifies all menu items in a menu root to be deleted. The option cannot be given with the -window_type option.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

`-root ContextMenuRoot`

ContextMenuRoot specifies the context menu root to from which the menu item will be added. A context menu root name groups menu items to be included in a pop-up context menu. A context menu is usually brought up by right clicking on

Feedback

a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

Description

This command deletes a menu item for the menu bar of a top level window. The menu hierarchy separator is denoted by "->". If there is a toolbar button or hotkeys defined for the menu being deleted they will also be deleted. If the path to the menu is a submenu that menu item and all its sub-items will be deleted.

The option -all may be used with a menu root name to remove all menu items from a menu. This is useful if a user wishes to customize or modify an entire context menu.

These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations.

The installation specific setup file is specified by the variable gui_custom_setup_file and will have a default value of $::synopsys/admin/setup/.synopsys_galileo_gui.tcl. This can be overridden in the .synopsys_dc.setup file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized.

The user setup file is ~/.synopsys_galileo_gui.tcl.

Examples

The following example deletes the Quit item from the File menu.

```
gui_delete_menu -menu "File->Quit"
```

- gui_custom_setup_files

Feedback

gui_delete_toolbar

Delete a toolbar with the specified name.

Syntax

string *gui_delete_toolbar* -name *ToolBarName*

```
[-window_type WindowTypeName]

ToolBarName      String
WindowTypeName   String
```

Arguments

`-name ToolBarName`

ToolBarName is the toolbar identifier for the toolbar to be deleted.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command deletes a toolbar and all of its toolbar items.

Examples

Delete a toolbar called mytoolbar.

```
gui_delete_toolbar -name mytoolbar
```

See Also

Feedback

- gui_get_toolbar_names
- gui_default_window_type
- gui_custom_setup_files

---

gui_delete_toolbar_item

Remove a toolbar button specified by the menu name from the specified toolbar.

Syntax

string *gui_delete_toolbar_item* -toolbar *ToolBarName*

```
<-menu MenuName|-separator SeparatorName>
[-window_type WindowTypeName]

ToolBarName      String
MenuName         String
SeparatorName    String
WindowTypeName   String
```

Arguments

`-toolbar ToolBarName`

ToolBarName specifies the toolbar to be modified.

`-menu MenuName`

ItemName specifies the hierarchical menu name for some menu item, that this toolbar item is associated with. This option is mutually exclusive with the -separator option.

`-separator SeparatorName`

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -item option.

`-window_type WindowTypeName`

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command deletes a toolbar item specified by *MenuName* or *SeparatorName* from the specified toolbar. Returns the name of the deleted toolbar item if successful.

Feedback

Examples

Delete the button bound to File->Quit from the toolbar mytoolbar.

```
gui_delete_toolbar_item -name mytoolbar -menu "File->Quit"
```

See Also

- gui_default_window_type
- gui_custom_setup_files

---

gui_delete_user_widget_item

Delete user widget items

Syntax

```
status gui_delete_user_widget_item
[ -parent window_id ]
{ -group string | -item string | -all }
```

Data Types

```
window_id  string
```

Arguments

`-parent window_id`

Specifies the parent container or group.

If the command is nested inside another gui_create_user_widget_group command then the parent group is inherited from the parent group.

Feedback

If the command is not nested, and is run from an initialization tcl command or callback tcl command, then the parent is defaulted to the associated container.

`-group` *string*

Specifies the group name to remove.

This can either be the unique group name or a group collection.

`-item` *string*

Specifies the item name to remove.

This can either be the unique item name or a item collection.

`-all`

If specified then all items in the dialog are removed.

Description

This command removes one or more control items from the specified user widget container.

Examples

The following example will create buttons, in a flow group, in the window toolbar container for subsequent Charts views. The deleteButton callback is called when button1 is clicked which deletes button2.

```
shell> proc deleteButton { args } {
shell>   gui_delete_user_widget_item -item button2
shell> }
shell> proc init_my_toolbar { args } {
shell>   gui_create_user_widget_group -name buttons -type flow {
shell>     set button1 [gui_create_user_widget_item -window $window -name
 button1 -type button]
shell>     set button2 [gui_create_user_widget_item -window $window -name
 button2 -type button]
shell>     set_attribute $button1 label "Button 1"
shell>     set_attribute $button2 label "Button 2"
shell>     set_attribute $button1 activated_proc deleteButton
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\.
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type $gui_default_window_type]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

Feedback

See Also

- gui_create_window
- gui_create_user_widget_item

---

gui_edit_vmbucket_contents

Edit the collection contents of a Visual Mode Bucket

Syntax

string *gui_edit_vmbucket_contents* -vmname *mode_identifier*

-name *bucket_identifier* [-add | -remove | -replace] [-collection *handle*]

```
string  mode_identifier
string  bucket_identifier
string  handle
```

Arguments

`-vmname mode_identifier`

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name bucket_identifier`

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-add`

Add the collection to the collection already in the bucket

`-remove`

Remove the collection from the collection already in the bucket

`-replace`

Replace the collection already in the bucket

`-collection handle`

Tcl object collection to be colored by this visual mode bucket.

Feedback

Description

The gui_edit_vmbucket_contents command modifies the collection stored in a visual mode bucket. The collection can either be appended to, removed, or replaced. The flags to control this are mutually exclusive.

Examples

Add the current selection to the collection in the bucket 0 of the SNAPSHOT visual mode:

shell> *gui_edit_vmbucket_contents -vmname SNAPSHOT -name 0 -add -collection [get_selection]*

See Also

---

gui_error_browser

Show or hide the Error Browser Dialog

Syntax

string *gui_error_browser*

[-hide | -show | -toggle]

Arguments

`-hide`

Hides the Error Browser Dialog.

`-show`

Shows the Error Browser Dialog. If no option flag is provided, this is the default.

Feedback

`-toggle`

Show the Error Browser Dialog if it is currently hidden, else hide it.

Description

The *gui_error_browser* command controls the visibility of the Error Browser Dialog. The Error Browser Dialog displays violations with physical shapes recorded by a checker, for example a DRC engine. This command is valid only when there is a design open. If the Error Browser Dialog is shown and it was not previously shown. If the Error Browser Dialog is shown and it was previously shown, it will show the error data last loaded.

Examples

The following example creates and shows the Error Browser Dialog:

```
gui_error_browser -show
```

---

gui_estimate_topology_timing

Runs *estimate_topology_timing* and displays the resulting report as tables in the GUI.

Syntax

```
status gui_estimate_topology
[-details 0 | 1 | 2]
[-summary]
[-stages]
[-segments]
[-plan object]
```

Arguments

`-details 0 | 1 | 2`

Specifies the level of details to be reported to the user.

`-summary`

Specifies the summary view. This is equivalent to setting the details level to 0.

`-stages`

Specifies the stages view. This is equivalent to setting the details level to 1.

`-segments`

Specifies the segments view. This is equivalent to setting the details level to 2.

`-plan object`

Specifies a single topology plan of interest. If this is not specified then all topology plans are reported.

Feedback

Description

The *gui_estimate_topology_timing* command runs the *estimate_topology_timing* command and presents the resulting report as tables form in the GUI.

Examples

The following examples writes out a summary of the *estimate_topology_timing* for all topology plans in a design.

```
prompt> gui_estimate_topology_timing -summary
```

See Also

- estimate_topology_timing

---

gui_eval_command

Executes and optionally logs a tool command language (Tcl) command.

Syntax

string *gui_eval_command*

```
-command command
[-echo]
[-history]
[-honor_preview | -preview]
```

Data Types

```
command    string
```

Arguments

`-command` *command*

Specifies the Tcl command to execute and to record in the command replay log.

`-echo`

Echoes the command and displays the command result in the console log view. By default, the tool does not echo the command or display the result in the log view.

`-history`

Appends the command to the command history list in the console history view. By default, the tool does not append the command to the command history list.

Feedback

`-honor_preview`

This option is mutually exclusive with the -preview option. Honors the Preview Command Only settting in the dialog. By default, the tool does not honor the Preview Command Only settting.

`-preview`

This option is mutually exclusive with the -honor_preview option. Runs the given command in preview mode, irregardless of the current preview mode set from a command dialog. When -preview is given, -echo is turned on since the previewed command cannot be seen in the xterm if -echo is turned off. As with all commands issued from command dialogs when in preview mode, if a script editor is present, then the previewed command is redirected to the scripte editor. Using this option does not set or clear the global preview mode in the application.

Description

This command executes a Tcl command and records it in the command replay log. Use the *-echo* option to echo the command and its result in the console log view Use the *-history* option to append the command to the command history list. Use the *-honor_preview* option to honor the Preview Command Only settting. Use the *-preview* option to preview the command only without executing it.

The result of a nested command is passed back as the result of *gui_eval_command*.

Examples

The following example evaluates the command "echo abc".

```
prompt> gui_eval_command -command {echo abc}
abc
```

The following example previews the command "echo abc".

```
prompt> gui_eval_command -command {echo abc} -preview
abc
```

---

gui_eval_task_command

Executes a command from a task assistant page

Syntax

string *gui_eval_task_command*

```
-command command
[-task taskName | -script]
```

Feedback

Data Types

```
command    string
command    taskName
```

Arguments

`-command` *command*

Specifies the Tcl command to execute and to add to the favorites and most-recently-used (MRU) palettes. The executed command is logged in the command log.

`-task` *taskName*

If this option is present, then the given task name is used when the command is added to the favorites and MRU palettes. If not present, then the current task name is used.

`-script`

This option is mutually exclusive with the -task option. If this option is present, the command is not run but is appended in the script editor.

Description

This command executes the given Tcl command and records it in the command replay log. Use the *-script* option to append the command to the script editor only without executing it.

The result of a nested command is passed back as the result of *gui_eval_task_command*.

Examples

The following example evaluates the command "echo abc".

```
prompt> gui_eval_task_command -command {echo abc}
abc
```

The following example adds the command "echo abc" to the script editor.

```
prompt> gui_eval_task_command -command {echo abc} -script
abc
```

---

gui_execute_menu_item

Execute a menu item in the currently active window.

Syntax

```
status gui_execute_menu_item
{ -menu menu_item_id }
```

Feedback

Data Types

menu_item_id string

Arguments

-menu *menu_item_id*

menu_item_id specifies the hierarchical name of the menu item to execute. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item in the File menu. These names are allowed to also specify the keyboard accelerator for the menu text which is specified with an embedded '&', but they are not required to do so.

Description

This command checks for the existence and enabled state of the given menu item in the currently active window. If it exists and is enabled, the menu item is executed.

The command returns and result value string from the executed menu item, if any.

Examples

The following example activates the main window named Toplevel.2, then executes the *Hierarchy Browser* menu item in the *View* menu in Tolevel.2.

```
shell> gui_set_active_window -window Toplevel.2
shell> gui_execute_menu_item -menu "View->Hierarchy Browser"
```

- gui_create_menu
- gui_set_active_window

---

gui_exist_pref_category

Check the existence of a preference category.

Syntax

bool *gui_exist_pref_category* -category *Category*

Category *String*

Arguments

-category *Category*

Category specifies the category.

Feedback

Description

This command checks the existence of a preference category. Return "1" if the specified category exists, otherwise return "0".

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_get_pref_keys
- gui_exist_pref_key
- gui_update_pref_file

---

gui_exist_pref_key

Check the existence of a preference key.

Syntax

bool *gui_exist_pref_key* -key *Key*

[-category *Category*]

```
Key              String
Category         String
```

Arguments

`-key` *`Key`*

Key specifies the preference key of interest.

`-category` *`Category`*

Category specifies the category. Default category will be used if missing.

Feedback

Description

This command checks the existence of a preference key given the key name and the preference category. Return "1" if the specified key exists, otherwise return "0".

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key

- gui_get_pref_keys
- gui_exist_pref_category
- gui_update_pref_file

---

gui_exist_window

Check for the existence of specified window or window type

Syntax

```
status gui_exist_window
{ -window window_id | -type window_type }
[ -parent window_id ]
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-window window_id`

Specifies the window id to test existence for.

This option is mutually exclusive with the *-type* option.

`-type window_type`

Specifies that the existence of a window of this window type is tested for.

Feedback

If the *-parent* option is specified then the existence of a window of this window type is tested for in the specified toplevel window.

If the *-parent* option is *not* specified then the existence of a window of this window type is tested for in any toplevel window.

This option is mutually exclusive with the *-window* option.

`-parent window_id`

Specifies the toplevel window to check for existence in.

Note: This option is only relevant if the *-type* option is specified.

Description

This command checks the existence of the specified window, or window type across toplevel windows or within a specified toplevel window.

The command returns "1" or "0" for success or failure respectively.

Examples

The following example will create a toplevel window and a child layout view window, then check the existence of the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> set layout_exist [gui_exist_window $x]
shell> if { $layout_exist == 1} {echo "layout exist" }
```

See Also

- gui_show_window
- gui_get_window_types
- gui_get_window_ids
- gui_set_active_window
- gui_get_current_window

Feedback

gui_explore_logic_hierarchy

Creates, expands, colors, and removes enclosing module boundaries for cells in the logical hierarchy. This command is typically called by the tool from the Color by Hierarchy section of the Hierarchy Exploration panel.

Syntax

```
module_boundaries gui_explore_logic_hierarchy
[-threshold threshold_ratio]
[-create | -expand | -collapse | -remove | -update | -query ]
[-color color_id]
[-nested]
[-force]
[cells]
[-rtl_cells rtl_cell_list]
```

Data Types

```
module_boundaries  string
threshold_ratio    real
color_id           integer
cells              collection
rtl_cell_list      collection
```

Arguments

`-threshold threshold_ratio`

Specifies the ratio to use when determining if a child hierarchical cell should have an enclosing module boundary created for it. Module boundaries are created if the size of the boundary relative to the total size is greater than *threshold_ratio*. For example, if the *threshold_ratio* is 0.03, logical hierarchies are ignored if they have a size smaller than 3 percent of total size.

By default, the ratio is specified by the *plan.explore.default_threshold* application option.

`-create`

Creates enclosing module boundaries for the specified logical hierarchical cells. If the *-nested* option isn't specified, Module boundaries are removed for the child cells of the specified logical hierarchical cells, otherwise see detail description in option *-nested*.

If the *-color* option isn't specified, a color will be automatically assigned.

`-expand`

Creates enclosing module boundaries for the child cells of the logical hierarchical cells (limited by a size threshold). If the parent cell already has a module boundary then, if the *-nested* option isn't specified, the module boundary

Feedback

for the parent will be removed, otherwise see detail description in option *-nested*. If module boundaries already exist on the child modules of the cell, the boundaries are re-created or removed as needed. For example, boundaries could be removed of the threshold changed.

The tool automatically assigns a color to the cells of each created module boundary.

`-collapse`

Removes the enclosing module boundaries for the currently selected module boundary and any sibling module boundaries, then creates a parent module boundary.

`-remove`

Removes the selected enclosing module boundary.

`-update`

Updates the shape of the enclosing module boundaries for the currently selected shape based on the current placement of their child cells.

If no cells are specified, all enclosing module boundaries are updated.

The application keeps track of the state of the created enclosing module boundaries, so updating update on module boundaries with no cell location changes will not normally modify the module boundary. To force an update, use the *-force* option.

The color of the cells within the module boundary will not be changed.

`-query`

Returns the instances for the existing enclosing module boundaries.

`-color` *`color_id`*

Specifies a color ID for the module boundary and its descendant. Valid *color_id* values are integer values from 0 to 63. If this option isn't specified, module boundaries and its descendant will be colored automatically. When creating the boundary, if *color_id* is 0, do not color the cells; Otherwise, color the objects with *color_id*.

`-nested`

Allow nested module boundaries to be created.

This option can only be used with the *-create* or *-expand* option.

If the *-create* is specified, a color will assign to the new created module boundaries and their child cells, existing module boundaries color will not change.

Feedback

If the *-expand* is specified, the specified module boundaries will not be removed.

`-force`

Forces update of enclosing module boundaries, even if the tool considers them up-to-date.

This option is not typically used, but can be added if you determine that an update is needed.

This option can only be used with the *-update* option.

`-rtl_cells` *`rtl_cell_list`*

Enclosing rtl cells are to be processed.

This option can only be used with the *-create* or *-remove* option.

If the *-create* is specified, the tool creates enclosing annotation shape for the specified RTL hierarchical cells. The tool automatically assigns a color to the cells of each RTL cell and the created annotation shape. If RTL cell has related logical cell, it also colored.

If the *-remove* is specified, the tool removed the annotation shape for the specified RTL hierarchical cells. The tool automatically assigned the parent cell's color to the RTL cells.

Description

This command supports hierarchy exploration by creating, expanding, managing, and removing enclosing module boundaries for the physical child cells of logical hierarchical cells. This command is typically called by the tool from the Color by Hierarchy section of the Hierarchy Exploration panel.

The command returns the created or queried module boundaries.

The enclosing module boundary can be created for specific logical hierarchical cells (*create* mode) or for all the child modules of logical hierarchical cells (*expand* mode). When creating child boundaries, the actual cells which have boundaries created is controlled by a size threshold. Cells with a size below the threshold are skipped.

The created module boundary is shaped so its rectilinear boundary encloses the bounding boxes of all the child cells in the logical hierarchy. This provides visual feedback of the standard cell and macro placement for the logical hierarchy, even if the child cells are not visible.

The created module boundary and child cells are set to the same cell color, so the association between the module boundary and child cells can be seen at all zoom levels.

The created module boundaries can also be removed (*remove* mode) or updated (*update* mode).

Feedback

Note: this command extends the functionality of the existing *explore_logic_hierarchy* command to support a more complex boundary (enclosing shape) and to support consistent module boundary and child cell coloring.

NOTE

This command does not require the gui to be open.

The command supports undo that is the undo command will restore the module boundaries and colors to their previous state.

Examples

The following example creates an enclosing module boundary for the ALU logical hierarchical cell using the auto color.

```
prompt> gui_explore_logic_hierarchy -create [get_cells ALU]
```

The following example creates enclosing module boundaries for the child cells of the top cell using the color which is auto assigned.

```
prompt> gui_explore_logic_hierarchy -expand
```

The following example removes the module boundary for the ALU logical hierarchical.

```
prompt> gui_explore_logic_hierarchy -remove [get_cells ALU]
```

The following example will remove the enclosing module boundaries for all cells.

```
prompt> gui_explore_logic_hierarchy -remove
```

The following example updates the module boundary for the ALU logical hierarchy.

```
prompt> gui_explore_logic_hierarchy -update [get_cells ALU]
```

The following example updates the enclosing module boundaries for all cells.

```
prompt> gui_explore_logic_hierarchy -update
```

See Also

- explore_logic_hierarchy
- set_colors

---

gui_export_utable

Export the UserTable to a value file.

Feedback

Syntax

string *gui_export_utable*

```
-name         Table_Name
[-file        File_Name [-tsv_mode] [-ssv_mode]]
[-filter      Filter]
[-tsv_mode]
[-ssv_mode]
[-add_col_type]
[-add_metadata]
[-overwrite]

Table_Name    String
File_Name     String
```

Arguments

`-name` *`Table_Name`*

The name of the user table to export to a CSV value file.

`-file` *`File_Name`*

The name of the file to write the table to, by default the name of the table is used with the '.csv' extension.

`-filter` *`Filter`*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-add_col_type`

This flag will add column type information to be added as a postfix to the header column names. This allows type information to be available if imported again by this tool at a later time.

`-add_metadata`

Add metadata to the top of the exported table. See the command gui_set_utable_meta for more information.

Feedback

`-overwrite`

This flag will force the destination file to be overwritten.

Description

```
This command exports the contents of the given UserTable into a CSV value
 file.
The first line contains all the column names and if the -add_col_type
 flag is
given, it also appends column data type information to the column names.
```

Examples

```
The following example just exports the given UserTable to a file with the
 same name
as the table plus a '.csv' extension.

shell> gui_export_utable -name my_table

The following example exports the UserTable 'my_table' to the filename
 'results' and
uses the Tab char as a delimiter. The resultant file will be called
 'results.tsv'.

shell> gui_export_utable -name my_table -file results -tsv_mode
```

---

gui_fill_utable

Fill generated data rows to an existing UserTable.

Feedback

Syntax

string *gui_fill_utable*

```
-name             Name

-file_column      Name
-file_suffix      Suffix
-file_dir         Directory
-label_column     Name
-label_value      Value
-date_column      Name
-tag_column       Name
-title_column     Name

Name              String
File_Name         String
Suffix            File Suffix String
Directory         Directory Path String
Value             Value String
```

Arguments

`-name` *Name*

The name of an existing UserTable that the new data rows should be added to.

`-file_column` *Directory*

The column name that is filled with the filenames found in the directory.

`-file_dir` *Directory*

The directory path to search for files matching the file suffix option.

`-label_column` *Name*

The column name that is filled with a label for each entry added.

`-label_value` *Value*

The label value used to fill the -label_column argument as each entry is added.

`-date_column` *Name*

The column name used to fill in the date of the file that was added.

`-tag_column` *Name*

The column name used to fill in the metadata tag of the file if it exists.

`-title_column` *Name*

The column name used to fill in the metadata title of the file if it exists.

Feedback

Description

Using the various options one can generate rows of data that include columns for file names, file dates, labels and if available in the file the tag and title meta data for all files found according to the specified file suffix and directory. For more information on Meta Data please see the command *gui_set_utable_meta*.

Examples

The following example creates a table of data where each row contains information about a CSV file that was found in the given directory. The filename is actual a link that when clicked will load that CSV file and make it a child of this table. Thus this basically creates a table of links to other tables represented by CSV files.

```
shell> gui_create_utable -name csv_toc \\
         -columns {status:boolean comment report file date tag title} \\

shell> gui_fill_utable -name csv_toc \\
         -file_column file \\
         -file_suffix ".csv" \\
         -file_dir "./csv_files/" \\
         -label_column report \\
         -label_value value_files \\
         -date_column date \\
         -tag_column tag \\
         -title_column title
```

---

gui_foreach_utable_row

Iterate/visit the given table row column values for the given filter and call a TCL proc.

Syntax

string *gui_foreach_utable_row*

```
-name             Table_Name
-action           Action
-columns          Column_List
[-filter          Filter_Expr]
[-data            Data]

Table_Name       String
Action           TCL Procedure Name
Column_List      StringList
Filter_Expr      String
Data             String
```

Arguments

`-name` *Table_Name*

The table name on which to visit all the rows filtered by the filter.

`-action` *Action*

The user TCL procedure that will be called on every row that matches the filter.

`-columns` *Column_List*

Provides a list of one or more column names whose data will be passed to the action procedure.

`-filter` *Filter_Expr*

To only visit a certain set of rows in the table you must ether first filter the table in the view or use this filter expression to only target the rows of interest.

`-data String`

Provides an optional data string that is passed to the user TCl proc.

Description

```
This command allows you iterate/visit each row in a table filtered
by the filter value and call a user given TCL procedure.
The procedure must accept two fixed arguments, the 'table_name'
and a 'user_data' argument which may be filled with the '-data' option.
```

Feedback

This is then followed by an argument for every column name given which will have the current row value for that column.
If no filter option is given the all rows will be visited unless the table is currently viewed, then all rows will be visited that match the current view filter setting.

Examples

The following example calls a print TCL procedure for every row that matches the filter.

```
shell>
  proc printVal { table data pin direction } {
    puts "table: $table, data: $data, pin: $pin, direction: $direction"
  }

  gui_foreach_utable_row -name $table \\
    -columns {{full_name} {direction}} \\
    -action printVal -filter {slack > 0.0}
```

The following example uses the gui_set_utable_values command to update the table values. This is not as efficient as calling the
 gui_set_utable_values
command for all filtered values but it gives you more control for each row update action.

```
shell>
  proc setVal { table data pin direction } {
    # Do some arbritary functions with the received data...
    # Update the table row itself:
    gui_set_utable_values -name $table -column direction \\
      -value $data -filter "{full_name} == $pin"
  }
  gui_foreach_utable_row -name $table \\
      -data out \\
      -columns {{full_name} {direction}} \\
      -action setVal -filter {slack > 0.0}
```

---

gui_get_annotations

Return a collection of layout annotations

Feedback

Syntax

string *gui_get_annotations*

[-window *window_name*] [-group *group_id*] [-within *region*] [-intersect] [-at *location*] [-filter *filter*] [-nocase] [-regexp]

```
string window_name
string group_name
string filter
rectangle region
location point
```

Arguments

`-window window_name`

Specifies the instance name of the layout window. If not specified implies all windows.

`-group group_name`

Specifies the annotation group name. If not specified implies all groups.

`-within region`

Search for annotations contained within the specified rectangle.

`-intersect`

Use this option with the -within option. When -intersect is specified, all annotations that touch the search rectangle are also returned.

`-at location`

Search for annotations that are close to the specified point.

`-filter filter`

Only return annotations that satisfy the filter expression.

`-nocase`

Ignore case in the filter expression. Option requires -filter.

`-regexp`

Use regular expressions in the filter expression. Option requires -filter.

Description

Returns a collection of gui_annotation objects that satisfy the requirements. You can use get_attribute to query properties of the annotations. Also some attributes may be modified with set_attribute.

Feedback

Examples

The following example retrieves all the annotations in the Layout.1 window.

```
shell> gui_get_annotations -window Layout.1
```

This example shows how to use the client_data attribute to find annotations with that setting.

```
shell> gui_get_annotations -filter client_data==MyData
```

This example shows how to find annotations that are within a specified rectangle

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}}
```

To also find the annotations that touch the search rectangle:

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}} -intersect
```

---

gui_get_bucket_option

Returns the value of a bucket option of a given visual or map mode.

Syntax

```
string gui_get_bucket_option
-map map_name
-bucket bucket_name
-option option_name
[-default]
```

Data Types

```
map_name          string
bucket_name       string
option_name       string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-bucket bucket_name`

Specifies the name of the bucket.

`-option option_name`

Specifies the name of the option to be set.

`[-default]`

Specifies that command has to return default option value.

Feedback

Description

This command returns an option value that are available for the bucket in the specified visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. The command can return either current or default value.

Examples

The following example returns the value of 'visible' option of 'light blue' bucket of 'Highlight' visual mode:

```
prompt> gui_get_bucket_option -map {Highlight} -bucket {light blue}
 -option {visible}
```

See Also

- gui_set_bucket_option
- gui_get_bucket_option_list
- gui_get_map_list
- gui_get_map_option
- gui_get_map_option_list
- gui_set_map_option

---

gui_get_bucket_option_list

Lists the available options for buckets in the specified visual mode or map mode.

Syntax

```
string gui_get_bucket_option_list
-map map_name
```

Data Types

```
map_name        string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

Description

This command displays a list of all options that are available for the buckets in the specified visual mode or map mode.

Feedback

Examples

The following example displays a list of the available options for buckets in the global route congestion map:

```
prompt> gui_get_bucket_option_list -map AREAPARTITION
```

See Also

- gui_set_map_option

---

gui_get_charts_data

Get charts data

Syntax

```
value gui_get_charts_data
{ -global | -model model_id | -view view_name |
-plot plot_name | -annotation annotation_name }
[ -column column_name ]
[ { -header | -row int } ]
-name string
[ -data string ]
```

Data Types

```
model_id          int
view_name         string
plot_name         string
annotation_name   string
column_name       int
value               string
```

Arguments

`-global`

Get global data.

`-model model_id`

Model to get data from.

Feedback

`-view` *`view_name`*

View to get data from.

`-plot` *`plot_name`*

Plot to get data from.

`-annotation` *`annotation_name`*

Annotation to get data from.

`-column` *`column_name`*

Column to get model data from.

Only used by the *model* option.

`-header`

get model data from header.

Only used by the *model* option.

`-row` *`int`*

Row to get model data from.

Only used by the *model* option.

`-name` *`string`*

Name of data to return.

The supported names depend on which object the data is extracted from:

For model the following names are supported:

value Get value of model horizontal header (using the *header* option) value or row value (using the *row* option). The column is specified using the *column* option.

num_rows Get number of rows in model.

num_columns Get number of columns in model.

header Get model header names. If column is specified using the *column* option then only the header for that column is returned.

row Get model row values for the row specified using *row* option.

column Get model column values for the column specified using *column* option.

duplicates Get rows with duplicate values (same value in all columns).

column_index Get model column index from name specified in *data* option.

Feedback

name Get the model name.

title Get the model title.

The following data names are queried on the specifed column (single value) or, if the column is not specified, then on all columns (list of values):

type Get model column type.

min or minimum Get model minimum column value.

max or maximum Get model maximum column value.

mean or avg or average Get model average column value.

monotonic Get if model column monotonic (increasing or descreasing)

increasing Get if model column increasing

num_unique Get number of unique model values in column.

unique_values Get unique model values in column.

unique_counts Get counts of each unique model value in column.

num_null Get number of null values in column.

median Get model median column value.

lower_median Get model lower median column value.

upper_median Get model upper median column value.

stddev or std_dev Get model standard deviation value.

outliers Get model outlier values.

For view the following names are supported:

plots return a list of all plots in the view.

annotations return a list of all annotations in the view.

selected_objects return a list of all selected objects in the view.

For plot the following names are supported:

model Model index.

view Parent view name.

annotations Get plot's annotation object ids.

objects Get plot's object ids.

Feedback

selected_objects Get plot's selected object ids.

errors Get plot's error messages.

For annotation the following names are supported:

view Parent view name.

plot Parent plot name.

The following global data the following names are supported:

models Get model indices

views Get view names.

plot_types Get plot type names.

plots Get all plots names.

column_types Get all column type names.

column_type.names Get names of parameters for specified column type (in *data* option).

annotation_types Get all annotation type names.

symbol_names Get all symbol names.

procs Get all user defined procedure names.

You can also use the special name "?" which will return a list of the supported names for the specified object.

`-data` *`string`*

Extra data needed to query some data values.

Returns

value

Returned value.

Description

Get data from model, view, plot type, plot objects or from global object.

If model is specified then the *column* and *header* or *row* should be specified.

Examples

The following example gets all the view names.

```
shell> set views [gui_get_charts_data -global -name views]
```

Feedback

The following example gets all the plots of the first view.

```
shell> set plots [gui_get_charts_data -view [lindex $views 0] -name
 plots]
```

The following example gets all the annotations of the first plot.

```
shell> gui_get_charts_data -plot [lindex $plots 0] -name annotations
```

The following example gets all the model names.

```
shell> set models [gui_get_charts_data -global -name models]
```

The following example gets the value at row 2, column 1 in the first mode.

```
shell> gui_get_charts_data -model [lindex $models 0] -name value -row 2
 -column 1
```

See Also

- gui_set_charts_data

---

gui_get_charts_property

Get charts property

Syntax

```
value gui_get_charts_property
{ -view view_name | -plot plot_name |
-annotation annotation_id }
-name string
```

Data Types

```
view_name       string
plot_name       string
annotation_id   string
value             string
```

Arguments

`-view view_name`

View to get property from.

`-plot plot_name`

Plot to get property from.

`-annotation annotation_id`

Plot or view annotation to get property from.

Feedback

`-name string`

Name of property to return.

The supported names depend on which object the property is extracted from but can be listed by using the special property name "?".

Returns

value

Returned value.

Description

Get property from view, plot, view annotation, plot annotation or plot objects.

Examples

The following example gets the position of an annotation in a plot.

```
shell> gui_get_charts_property -plot $plot -annotation $annotation -name
 position
```

See Also

- gui_set_charts_property

---

gui_get_clock_tree

Returns clock tree fanin or fanout cone for given clock and start pin.

Syntax

status *gui_get_clock_tree*

```
-clocks clocks
-from from_pins
-trace_direction forward | backward | both
```

Data Types

```
clocks     string or collection
from_pins  string or collection
```

Arguments

`-clocks clocks`

Specifies the clocks on which the clock tree fanin or fanout cone is calculated.

`-from from_pins`

Specifies the start pins from which the fanin or fanout cone is traced.

Feedback

`-trace_direction forward | backward | both`

Specifies the trace direction. The trace direction must be one of following values:

- forward: Trace forward through the clock tree (get fanout pins)
- backward: Trace backward through the clock tree (get fanin pins)
- both: Trace both forward and backward (get both fanout and fanin pins)

Description

Returns a collection of clock tree fanin or fanout pins for given clock and start pin.

Examples

The following example returns the fanout pins of clock CLK3, starting from selected pin.

```
prompt> gui_get_clock_tree \\
   -clocks [get_clocks CLK3] -from [get_selection] -trace_direction
 forward
```

See Also

- get_clocks

---

gui_get_color_value

Get the RGB color value for given color index or name, else return all color information for the palette.

Syntax

string *gui_get_color_value [index]*

```
[-palette string]
[-color_name string]
```

Arguments

index

Use given color index number. An error message is posted if the given index is greater than the maximum index allowed for the current or given Palette. This argument is exclusive with option -color_name.

-palette

User given palette name, the default is 'highcontrast'. Valid values are: highcontrast, highlight, default_tech, qt, style. An error message is printed if an invalid palette name is given.

Feedback

-color_name

Use given color name. Must be valid for the current/given palette. If an invalid color name is given an error message is posted. This option is exclusive with the 'index' argument.

Description

Get the RGB color value string for the given color name or index value.

If no argument is given the command will return a TCL list of lists. One list for every color in the current/given palette. The list for each color contains the index number, the RGB color value and, if available, a color name.

Examples

```
shell> gui_get_color_value 10
#005000

shell> gui_get_color_value -color_name magenta
#ff00ff

shell> gui_get_color_value
{0 #000000 }
{1 #464646 }
{2 #00ff64 }
{3 #78bec8 }
{4 #ff00ff magenta}
{5 #00af96 }
{6 #0000be }
{7 #00ffff cyan}
{8 #b1f476 light_green}
{...}
```

---

gui_get_current_task

Get the name of the current task.

Syntax

string *gui_get_current_task*

Description

The gui_get_current_task command queries the name of the current task.

See Also

- gui_create_task
- gui_get_current_task_item

Feedback

- gui_get_current_task_page
- gui_set_current_task
- gui_get_task_list

---

gui_get_current_task_item

Get the name of the current task item.

Syntax

string *gui_get_current_task_item*

Description

The gui_get_current_task_item command queries the name of the current task item.

See Also

- gui_get_current_task
- gui_get_current_task_page
- gui_set_current_task
- gui_get_task_list

---

gui_get_current_task_page

Get the name of the current task page.

Syntax

string *gui_get_current_task page*

Description

The gui_get_current_task_page command queries the name of the current task page.

See Also

- gui_create_task
- gui_get_current_task
- gui_get_current_task_item
- gui_set_current_task
- gui_get_task_list

Feedback

gui_get_current_window

Retrieves the window ID of the active top-level or view window.

Syntax

```
string gui_get_current_window
[ -toplevel | -view | -parent parent_window_id ]
[ -hier_name ]
[ -types window_type_list ]
[ -mru ]
```

Data Types

```
parent_window_id    string
window_type_list    list
```

Arguments

`-toplevel`

Retrieves the active top-level window unless you also specify the *-types* option.

If you also specify the *-types* option, the *-toplevel* option retrieves the most recently active top-level window that has one of the specified window types.

The *-toplevel*, *-view*, and *-parent* options are all mutually exclusive.

`-view`

Retrieves the active view window in the active top-level window unless you also specify the *-types* option, the *-mru* option, or both.

if you also specify the *-types* option but not the *-mru* option, the *-view* option retrieves the most recently active view window with one of the specified window types in the active top-level window.

if you also specify the *-mru* option but not the *-types* option, the *-view* option retrieves the most recently active view window in any of the open top-level windows.

If you also specify both the *-types* option and the *-mru* option, the *-view* option retrieves the most recently active view window that has one of the specified window types and is in an open top-level window.

The *-view*, *-toplevel*, and *-parent* options are all mutually exclusive.

`-parent parent_window_id`

Retrieves the active view window in the specified top-level window unless you also specify the *-types* option.

Feedback

If you also specify the *-types* option, the *-parent* option retrieves the most recently active view window that has any of the specified window types and is in the specified top-level window.

The *-parent*, *-toplevel*, and *-view* options are all mutually exclusive.

`-hier_name`

Returns the window ID in Qtcl format, which is similar to a full path name for the window, for use with the qtcl_* commands.

Note that a value returned in this format is not usable by gui_* commands.

`-types` *`window_type_list`*

Forces the tool to retrieve a window with one of the specified window types.

Use this option to restrict the search to certain types of windows. If you specify multiple types, they should be consistent (all toplevel window types or all view window types), but nonconsistency is not considered an error. The first type in the list determines whether the tool retrieves a top-level window or a view window when the *-toplevel* and *-view* options are not specified.

When you use the *-types* option, you should not use the *-toplevel* option or the *-view* option because the tool can determine from the list whether the window should be a top-level window or a view window. If you specify one of these options, any types that do not correspond to the option are silently ignored. For example, if you specify *-view*, then all top-level types are ignored.

`-mru`

Forces the tool to retrieve the most recently active view window from among all the open top-level and view windows. This option is effective only when you specify the *-view* option or when all the window types you specify with the *-types* option are view window types.

Description

This command retrieves the window ID of the active top-level or view window based on the options that you specify, or returns an empty string if no match is found.

A view window is a child window of a top-level window and is created with the *gui_create_window* command.

If you do not specify the *-toplevel*, *-view*, and *-parent* options, the tool uses the *-types* option to determine the window type. If you also do not specify the *-types* option, the tool uses the *-toplevel* option by default.

Feedback

Examples

The following example retrieves the active top-level window:

```
prompt> gui_get_current_window -toplevel
```

The following example retrieves the active view window:

```
prompt> gui_get_current_window -view
```

The following example retrieves the most recently active layout view:

```
prompt> gui_get_current_window -types "Layout" -mru
```

The following example return $cons:

```
prompt> set top1 [gui_create_window -type LayoutWindow]
prompt> set top2 [gui_create_window -type LayoutWindow]
prompt> set cons [gui_create_window -type Layout -parent $top]
prompt> gui_get_current_window -parent $top
```

- gui_create_window

---

gui_get_display_view

Returns the display view type (abstract, design, frame, layout, or outline) used in the layout when cell-specific views are active. Views are set with the *gui_set_display_view* command.

Syntax

string *gui_get_display_view*

```
-cells cell_list
```

Data Types

```
cell_list  list
```

Feedback

Arguments

`-cells` *cell_list*

Specifies the physical cells for which to report the view.

Description

This command retrieves the cell-specific display view value. For this command, the view is set with the *gui_set_display_view* manpage for more detailed information.

Examples

The following example returns the view setting for cells A and B. The first command shows that cell A has no display view set. The second command shows that the display view type for cell is design.

```
prompt> gui_get_display_view -cells A
prompt> gui_get_display_view -cells B
design
```

See Also

- gui_set_display_view

---

gui_get_error_browser_option

Get Error Browser Dialog option values

Syntax

string *gui_get_error_browser_option*

-grouping | -show_mode | -view_mode | -zoom_factor | -hide_fixed | -hide_ignored | -hide_waived | -hide_null_net | -autoselect_first_error_id | -advance_to_next_unfixed_error | -dim | -show_open_locator_nodes | -show_tooltip | -show_command_buttons | -highlight_objects | -auto_set_object_visible | -auto_set_object_visible_type

Arguments

```
-grouping | -show_mode | -view_mode | -zoom_factor |
-hide_fixed | -hide_ignored | -hide_waived | -hide_null_net |
-autoselect_first_error_id | -advance_to_next_unfixed_error | -dim
| -show_open_locator_nodes | -show_tooltip -show_command_buttons
| -highlight_objects | -auto_set_object_visible |
-auto_set_object_visible_type
```

Mutually exclusive required option to specify the Error Browser option value to query.

Feedback

Description

This command gets the value of the requested option setting for the Error Browser. One option value can be queried at a time.

The *-grouping* option returns *type* or *layer* which indicates whether errors are grouped by types or layers.

The *-show_mode* option returns *all*, *selected*, or *none* which indicates whether all errors, selected errors, are no errors are shown in layout views.

The *-view_mode* option returns *zoom*, *pan*, of *off* which indicates whether the layout view zooms to, pans to, or does not change to the currently selected errors in the Error Browser.

The *-zoom_factor* option returns a float value between *0.1* and *10.0* and indicates the zoom factor used when the view_mode is zoom.

The *-hide_fixed* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether fixed errors are hidden from display in the Error Browser and layout views.

The *-hide_ignored* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether ignored errors are hidden from display in the Error Browser and layout views.

The *-hide_waived* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether waived errors are hidden from display in the Error Browser and layout views.

The *-hide_null_net* option returns *true* to mean "hidden" or *false* to mean "not hidden" and indicates whether errors associated with null nets are hidden from display in the Error Browser and layout views.

The *-autoselect_first_error_id* option returns *true* to mean "auto-select first error ID" or *false* to mean "do not auto-select first error ID" and indicates whether the first error ID is automatically selected when an error set is selected in the Error Browser.

The *-advance_to_next_unfixed* option returns *true* to mean advance to next unfixed error when an error is fixed or *false* to mean advanced to next fixed/unfixed error.

The *-dim* option returns *true* to mean "dimmed" or *false* to mean "not dimmed" and indicates whether layout views are dimmed when errors are displayed.

The *-show_open_locator_nodes* returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether net nodes are highlighted along with the open locator flylines for selected open locator errors.

The *-show_tooltip* returns *true* to mean show tooltips or *false* to mean don't show tooltips in the error browser list and details panes.

Feedback

The *-show_command_buttons* returns *true* to mean show the commannd buttons or *false* to mean don't show the command buttons in the error browser.

The *-highlight_objects* returns *true* to mean "highlighted" or *false* to mean "not highlighted" and indicates whether associated design objects are highlighted in the layout view for selected errors.

The *-auto_set_object_visible* returns whether auto set layout/object visibility is turned on or not.

The *-auto_set_object_visible_type* returns whether auto set layout/object visibility turns on layers/objects incrementally (the default) or exclusively.

Examples

The following example gets the grouping option

gui_get_error_browser_option -grouping

The following example gets whether layout views are dimmed when errors are displayed

gui_get_error_browser_option -dim

- gui_error_browser
- gui_set_error_browser_option

---

gui_get_error_data

Creates a collection of physical DRC error data that are currently shown in the error browser.

Syntax

```
collection gui_get_error_data
```

Description

The *gui_get_error_data* command creates a collection of physical DRC error data that are currently shown in the error browser.

You can use the *get_drc_error_data* command at the command prompt, or you can nest it as an argument to another command (for example, *query_objects*). In addition, you can assign the *gui_get_error_data* result to a variable.

When issued from the command prompt, *gui_get_error_data* behaves as though *query_objects* had been called to display the objects in the collection.

Feedback

Examples

The following example queries the physical DRC error data that are currently shown in the error browser. Although the output looks like a list, it is not. The output is just a display.

```
prompt> gui_get_drc_error_data
{"my_design_dppinassgn.err"}
```

See Also

- gui_open_error_data
- gui_close_error_data

---

gui_get_errors

Creates a collection of violation objects or errors in the Error Browser.

Syntax

collection *gui_get_errors*

[-visible] [-current] [-selected] [-fixed 0 | 1 | true | false] [-ignored 0 | 1 | true | false] [-id *ErrorObjectIDList*] [-data_name *ErrorDataName*]

```
ErrorObjectIDList    list
ErrorDataName        string
```

Arguments

`-visible`

Return errors that are currently visible in the Error Browser. This option will be exclusive to *-data_name* and *-id*.

`-current`

Return errors in the current error set, visible and hidden in the Error Browser. This option will be exclusive to *-data_name* and *-id*.

`-selected`

Return selected errors. This option will be exclusive to *-data_name* and *-id*.

`-fixed`

If this option is present, will only get errors that match the specified fixed state.

`-ignored`

If this option is present, will only get errors that match the specified ignored state.

Feedback

`-id`

Return errors specified by error object ids. It will only work with *-data_name* and exclusive to *-visible*, *-current* and *-selected*.

`-data_name` *`ErrorDataName`*

ErrorDataName specifies the error data to get error objects. It will only work with *-id* and exclusive to *-visible*, *-current* and *-selected*.

The error data name may be omitted. If omitted, selects the design, the parent of all open error data.

Description

This command creates a collection of violation objects or errors in the Error Browser.

If *-visible* option specified, return all visible errors in the Error Browser. If *-current* option specified, return all errors in the current error set. If *-selected* option specified, return all selected errors. *-visible*, *-current* and *-selected* will be exclusive to *-id* and *-data_name*. If specified together, an error message will be issued.

If *-fixed* option specified, if true then return all fixed errors, else return all non-fixed errors. If *-ignored* option specified, if true then return all ignored errors, else return all non-ignored errors. If *-fixed* and *-ignored* are specified together, return a combination of each result.

If *-id* option specified, return all errors based on the id list from specified error data. If *-data_name* option specified, return errors from the specified data. If the *-data_name* option is omitted, selects the design, the parent of all open error data. *-id* and *-data_name* have to be specified together. They will be exclusive to *-visible*, *-current* and *-selected*.

Examples

The following example gets errors from current error set and with fixed status 1.

```
gui_get_errors -current -fixed 1
```

The following example gets errors from zroute.err with id 1 and 2.

```
gui_get_errors -data_name zroute.err -id {1, 2}
```

Feedback

gui_get_focus_objects

Returns collection of objects associated with the focus target net.

Syntax

```
collection gui_get_focus_objects
```

Data Types

```
object_collection  collection
```

Description

The *gui_get_focus_objects* command returns the net connectivity objects associated with the focus nets.

Examples

The following example selects the net connectivity objects associated with the current focus target.

```
prompt> change_selection [gui_get_focus_objects]
```

gui_get_hierview_data

Get various state about the Hierarchy View and its sub-views. [Default return last used Hierarchy View name]

Syntax

string *gui_get_hierview_data*

```
[-view             View_Name]
[-tree_type]
[-tree_attr_group]
[-tree_filter]
[-map_area]
[-map_color]
[-childlist_name]
[-childlist_attr_group]
[-childlist_filter]
[-sub_view]
[-columns]
[-values           Column_Name]
[-elide]
[-attr]

View_Name      String
Column_Name    String
```

Feedback

Arguments

`-view` *`View_Name`*

Use the given HierView window name (ex: Hier.1). Default is to get the most recent used HierView window name.

`-tree_type`

Get the current Hier Tree type (logical | rtl). Note: RTL is only available in RTLA.

`-tree_attr_group`

Get and return the current Hier Tree attribute group name.

`-tree_filter`

Get and return the current Hier Tree filter expression.

`-map_area`

Get and return the Hier Map Area attribute group name.

`-map_color`

Get and return the Hier Map Color attribute group name.

`-childlist_name`

Get and return the current ChildList sub-view name.

`-childlist_attr_group`

Get and return the current ChildList attribute group name.

`-childlist_filter`

Get and return the current ChildList filter expression.

`-sub_view`

Get and return the current active sub-view type. The sub-view types are 'hier_tree', 'hier_map' and 'child_list'.

`-columns`

Get and return a list of all column name(s) of all selected table cells.

`-values` *`Column_Name`*

Get and return a list of all selected table cell value(s) in the given column name. *Note*: Any of the column value(s) in the row of the selected cell(s) can be retrieved.

`-elide`

Get and return the current text elide for the view.

Feedback

`-attr`

Get the attribute name for the given column short name (display label).

Description

```
This command allows you to get various current Hierarchy View related
 view settings
and selected table cell data.
```

See Also

- gui_set_hierview_data

---

gui_get_highlight

Get a collection of highlighted objects.

Syntax

string *gui_get_highlight*

```
[-color color_id | -all_colors]
[-return_select_bus | -more_than ]

string          color_id
collection      clct
```

Arguments

`-color color_id`

Specifies the color of objects to be returned. If neither -color nor -all_colors is used, the current color is assumed. The allowed colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

`-all_colors`

Specifies that all highlighted objects are to be returned.

`-return_select_bus`

Create a new selection bus in which to store the result instead of returning a collection of objects.

`-more_than`

Return 1 if more than the specified number of objects would be returned, otherwise 0.

Feedback

Description

The gui_get_highlight command returns a collection of objects highlighted with the specified colors.

Examples

Get a collection of green highlighted objects.

shell> gui_get_highlight -color green

Get a collection of all highlighted objects.

shell> gui_get_highlight -all_colors

Query if any objects are highlighted

shell> gui_get_highlight -all_colors -more_than 0

See Also

- gui_change_highlight
- gui_get_highlight_options
- gui_set_highlight_options

---

gui_get_highlight_options

Query the options that control highlighting.

Syntax

string *gui_get_highlight_options*

```
[-current_color | -all_colors | -auto_cycle_color]
```

Arguments

`-current_color`

This option returns a string which is the current highlight color, or the default color for highlighting operations.

`-all_colors`

This option returns Tcl list of all of the colors which are allowed to be used for highlighting.

`-auto_cycle_color`

This option returns the current value of the auto cycle setting ("true" or "false").

Feedback

Description

The gui_get_highlight_options command queries the settings which control highlighting. Exactly one option must be provided.

Examples

Get the current highlight color.

shell> gui_get_highlight_options -current_color

Get all highlight colors.

shell> gui_get_highlight_options -all_colors

See Also

- gui_change_highlight
- gui_get_highlight
- gui_set_highlight_options

---

gui_get_image_view_data

Get data from images in image view

Syntax

```
status gui_get_image_view_data
-window window_name
{ -global | -image image_name }
-name string
[ -data string ]
```

Data Types

```
window_name  string
image_name   string
```

Arguments

`-window window_name`

Specifies the name of the image view to get the data in.

`-global`

Specifies that a global value is being queried.

`-image image_name`

Specifies that value is being queried for the specifed image.

Feedback

`-name` *string*

p Specifies the name of the global or image value being queried.

Global Names

proc, layout, scale, diff, diff_auto_load, diff_scale, diff_src, diff_dest, movie, movie_auto_load, movie_scale, movie_delay, movie_state, movie_frame, commom_scale, images, selected_images

proc

tcl proc to be called when the user interacts with an image.

layout

Image layout type.

scale

Image scale factor.

diff

Is diff area currently displayed.

diff_auto_load

Is diff area auto loaded.

diff_scale

Diff area scale factor.

diff_src

Image name used for diff source.

diff_dest

Image name used for diff destination.

movie

Is movie area currently displayed.

movie_auto_load

Is movie area auto loaded.

movie_scale

Movie area scale factor.

movie_delay

Feedback

Movie area delay.

movie_state

Movie view state (play or pause)

movie_frame

Movie frame number.

common_scale

Common scale option enabled.

images

Image names.

selected_images

Selected image names.

Image Names

name, ind, file, format, coords, title, window, date, value_names, value, value_type

name

Unique image name (generated when image added).

ind

Image index (0 to number_of_images - 1)

file

Associated image filename (if not encoded in data file).

format

Image file format as used by gui_write_window_image command.

coords

Bounding box of the image (bottom_left to top_right) in view (design) coordinates.

title

Image title.

window

Window type the image was saved from.

Feedback

date

Date image was saved.

value_names

List of names of extra values stored on image.

value

Value for specified name.

NOTE: in this case the data option provides the name of the value to return.

value_type

Value type for specified name.

`-data` *`string`*

Specifies extra data for the global or image data.

See details on individual value names to see if this is needed or not.

Description

The *gui_get_image_view_data* command gets global or individual data values for images from the image view.

Examples

The following example gets the tcl proc for the current view.

```
shell> set view [gui_get_current_window -type ImageView]
shell> gui_get_image_view_data -window $view -global -name proc
```

See Also

- gui_set_image_view_data
- gui_get_current_window

---

gui_get_layer_widths

Returns a list of widths per layer for route editing.

Syntax

```
values gui_get_layer_widths
-layer layer_name
[ { -default | -current | -user } ]
```

Feedback

Data Types

```
layer_name  string
values      list
```

Arguments

`-layer` *layer_name*

Specifies the routing layer for which to query the widths.

`-default`

Returns the list of widths to use by default, if the user has not set up their own list of layers.

The default list consists of:

- layer minimum width
- layer default width
- any NDR widths for layer

`-current`

Returns the list of widths that is used by the editor. If the user specified a list then it will be returned, otherwise the default list will be returned.

`-user`

Returns the list of widths explicitly specified by the user. This may be an empty list if no values were specified by the user via *gui_set_layer_widths*.

Description

This command returns a list of discrete widths; these widths are used by the route editor.

By default the value returned by *-current* will be returned.

Examples

The following example returns the user defined widths for layer 'M1'.

```
prompt> gui_get_layer_widths -layer M1 -user
```

See Also

- gui_set_layer_widths

---

gui_get_map

Retrieves attributes for a specified map mode.

Feedback

Syntax

string *gui_get_map*

```
-name identifier
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
[-icon_file]
[-update_cmd]
[-float]
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]
```

Data Types

```
identifier     string
```

Arguments

`-name` *identifier*

Specifies the name of the map mode to be queried.

`-buckets`

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

`-title`

Returns the title string.

`-help_topic`

Returns the help topic string.

`-infotip`

Returns the InfoTip string.

`-discrete`

Returns a true or false value that indicates whether the buckets of this map mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this map mode was created, and cannot be changed.

`-icon_file`

Returns the gui menu icon file.

Feedback

`-update_cmd`

Returns the Tcl command that is executed when the map mode is accessed. A typical use for this option is to update the state of the map mode if its contents are likely to change under certain circumstances.

`-float`

Returns a true or false value indicating whether the map mode buckets have a floating point range.

`-top_exaggeration`

Returns the top bucket exaggeration.

`-mid_exaggeration`

Returns the middle bucket exaggeration.

`-bot_exaggeration`

Returns the bottom bucket exaggeration.

Description

The *gui_get_map* command queries the option values of an existing map mode.

Examples

To retrieve names of the buckets in the map mode named "densityMap", use the following command:

```
prompt>gui_get_map -name densityMap -buckets
```

See Also

- gui_get_mapbucket

---

gui_get_map_list

Lists the current visual and map modes.

Syntax

```
string gui_get_map_list
```

Arguments

The *gui_get_map_list* command has no arguments.

Description

The *gui_get_map_list* command returns a list of existing visual and map modes.

Feedback

Examples

The following example gets the names of all available visual and map modes:

```
prompt> gui_get_map_list
```

See Also

- gui_show_map
- gui_update_vm

---

gui_get_map_option

Gets the value for an option in the specified visual mode or map mode.

Syntax

```
string gui_get_map_option
-map map_name
-option option_name
[-default]
```

Feedback

Data Types

```
map_name        string
option_name     string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-option option_name`

Specifies the name of the option to be set.

`[-default]`

Gets the option default value.

Description

This command gets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You can get set option specific value or its default value.

Examples

The following example gets the number of bins in the global route congestion map:

```
prompt> gui_get_map_option -map AREAPARTITION \\
        -option num_bins -value 9
```

See Also

- gui_get_bucket_option
- gui_get_bucket_option_list
- gui_get_map_list
- gui_set_map_option
- gui_get_map_option_list
- gui_set_bucket_option

---

gui_get_map_option_list

Lists the available options for the specified visual mode or map mode.

Feedback

Syntax

```
string gui_get_map_option_list
-map map_name
```

Data Types

```
map_name        string
```

Arguments

-map *map_name*

Specifies the name of the visual mode or map mode.

Description

This command displays a list of all options that are available for the specified visual mode or map mode.

Examples

The following example displays a list of the available options for the global route congestion map:

```
prompt> gui_get_map_option_list -map AREAPARTITION
```

See Also

- gui_get_bucket_option
- gui_get_bucket_option_list
- gui_get_map_list
- gui_get_map_option
- gui_set_bucket_option
- gui_set_map_option

---

gui_get_mapbucket

Gets attributes for Map Mode Bucket

Syntax

string *gui_get_mapbucket*

```
-map mode_identifier
-name bucket_identifier
[-infotip]
[-color]
```

Feedback

```
[-pattern]
[-exaggeration]
[-number]
[-maxval]
[-minval]
[-visible]
[-special]
[-title]
[-objcount]
```

Data Types

mode_identifier string
bucket_identifier string

Arguments

`-map` *mode_identifier*

Specifies the map mode to which the bucket is a member. The map mode must already exist.

`-name` *bucket_identifier*

Specifies the name of the map mode bucket to be queried. To see the list of buckets associated with a specific map mode use the gui_get_map command with the -buckets option.

`-infotip`

Return infotip string.

`-color`

Return bucket rendering color.

`-pattern`

Return bucket rendering fill pattern.

`-exaggeration`

Return bucket min pixel exaggeration value.

`-number`

Return bucket display number.

`-maxval`

Return bucket maximum value.

`-minval`

Return bucket minimum value.

Feedback

`-visible`

Return visibility.

`-special`

Return whether bucket is special.

`-title`

Return bucket title.

`-objcount`

Return the number of objects in the bucket.

Description

The gui_get_mapbucket command queries an instance of a map mode bucket for the specified option values. The values are returned in a list of option-value pairs.

Examples

Query the current color for the bucket named "Bucket10" in the map mode "densityMap":

```
prompt> gui_get_mapbucket -map densityMap -name Bucket10 -color
```

Query the current color and pattern for the bucket named "Bucket10" in the map mode "densityMap":

```
prompt> gui_get_mapbucket -map densityMap -name Bucket10 -color -pattern
```

See Also

- gui_get_map

---

gui_get_menu_roots

Return a sorted list of all menu roots used by the application.

Syntax

string *gui_get_menu_roots* [-window_type *string*]

```
string string
```

Arguments

`-window_type string`

Specifies the type of window to return menu roots for.

Feedback

Description

This command returns a list of all the menu roots used by the application. The menu roots include menu roots used by toplevel menu bars and menu roots used by context menus. A menu root is used to group menu items that share the same menu root together. All items under each toplevel window's menu bar shares the same menu root; similarly, all items in a context menu (menu brought up with right mouse click in a window) shares the same context menu root.

See Also

- gui_create_menu

---

gui_get_mouse_tool_option

Get the value of a mouse tool option

Syntax

string *gui_get_mouse_tool_option* -tool *string*

-option *string*

```
string string
string string
```

Arguments

`-tool string`

Tool to get option for.

`-option string`

Option to get.

Description

This command returns value of a mouse tool option .

Examples

```
> gui_get_mouse_tool_option -tool SELECT -option InputMode
Smart
```

See Also

- gui_mouse_tool
- gui_set_mouse_tool_option

Feedback

gui_get_performance_log_option

Gets the current option value controlling performance log behavior.

Syntax

```
string gui_get_performance_log_option
```

Description

This command is used to query the current setting for the performance log which is set by gui_set_performance_log_option.

Examples

```
The following example sets, then gets the current setting.

prompt> gui_set_performance_log_option -commands {gui_zoom
 win_select_objects}
prompt> gui_get_performance_log_option
commands: gui_zoom win_select_objects
```

See Also

- gui_log_performance
- gui_set_performance_log_option

gui_get_pref_categories

Return a list of the current preference categories.

Syntax

string *gui_get_pref_categories*

Description

This command returns a tcl list of the current preference categories.

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type

Feedback

- gui_remove_pref_key
- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_pref_keys

Return a list of preference keys under the specified category.

Syntax

string *gui_get_pref_keys* -category *Category*

```
Category        String
```

Arguments

```
-category Category
```

Category specifies the category to use.

Description

Return a list of preference keys under the specified category.

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key
- gui_get_pref_categories
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

Feedback

gui_get_pref_value

Get the value of a preference key.

Syntax

string *gui_get_pref_value* -key *Key* [-category *Category*]

```
Key             String
Category        String
```

Arguments

`-key` *Key*

Key specifies the key to retrieve the value from.

`-category` *Category*

Category specifies the category to search for the key. If not specified, a default category will be used.

Description

This command retrieves the value of a preference key from the specified key name and category.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command *gui_get_pref_value* is then used to retrieve the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
set x [gui_get_pref_value -category my_category -key some_key]
```

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_set_pref_value
- gui_get_pref_value_type
- gui_remove_pref_key

Feedback

- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_pref_value_type

Get the data type of the value of a preference key.

Syntax

string *gui_get_pref_value_type* -key *Key* [-category *Category*]

```
Key             String
Category        String
```

Arguments

`-key` *Key*

Key specifies the key to retrieve the value type from.

`-category` *Category*

Category specifies the category to search for the key. If not specified, a default category will be used for searching the key.

Description

This command retrieves the data type of the value of a preference key from the specified key name and category.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200. The command *gui_get_pref_value_type* is then used to retrieve the data type of the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type
 integer -value 200
set x [gui_get_pref_value_type -category my_category -key some_key]
{comment: x should be equal to "integer" }
```

Feedback

See Also

- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_presets

Gets list of preset name for object specified by category

Syntax

```
string gui_get_presets
-category category
[-system]
[-shared]
```

Data Types

```
category    string
```

Arguments

`-category` *category*

Specifies the name of the category that the presets be retrieved from.

`-system`

Return system presets. This option is mutually exclusive with the -shared option.

`-shared`

Return shared presets. This option is mutually exclusive with the -system option.

Description

This command retrieves the list of presets for a category.

Feedback

Examples

The following example gets the system presets for the Layout.

```
prompt> gui_get_presets -category Layout -system
```

See Also

- gui_set_preset

---

gui_get_region

Returns the coordinates of the current region rectangle or rectilinear polygon.

Syntax

string *gui_get_region* [-points]

[-type]

Arguments

`-points`

get region points

`-type`

get type of the region (point, line, rectangle, rectilinear, polygon or path)

Description

This command returns the coordinates of the rectangle or rectilinear polygon that defines the current region in layout region mode.

Note that the preferred command for typical extension writing is usually *gui_set_layout_user_command* instead of *gui_get_region* because *gui_set_layout_user_command* has snapping, mouse up drag, cancel, and user prompt capabilities.

Examples

```
prompt> gui_get_region
{{-1743.945 18.357} {42.833 1523.657}}
```

See Also

- gui_set_region
- gui_set_layout_user_command

Feedback

gui_get_setting

Gets a setting on the specified window.

Syntax

string *gui_get_setting*

```
-window WindowID
{ -setting Setting | -list }

WindowID         String
Setting         String
```

Arguments

`-window WindowID`

WindowID specifies the window to get the setting

`-setting Setting`

Setting specifies the setting to get

`-list`

Specifies that the list of available settings needs to be returned

Description

Gets the list of available settings on the specified window. Windows are views or top level windows. The setting is a property of the window. The returned value is a string which has the type of the setting being read. Some windows might not have this function implemented.

Examples

```
shell> gui_get_setting -window Layout.1 -setting showCell
1

shell> gui_get_setting -window Layout.1 -setting viewLevel
2
```

See Also

- gui_set_setting

gui_get_task_list

Lists all the available task names.

Feedback

Syntax

string *gui_get_task_list*

Description

The gui_get_task_list command queries the names of all available tasks.

Description

prompt> *gui_get_task_list* all {Block Implementation} {Design Planning}

---

gui_get_task_page

Return the name of the task page for the given task item.

Syntax

string *gui_get_task_page*

Syntax

gui_get_task_page

```
-task          TaskName
-item          ItemName

TaskName         String
ItemName         String
```

Arguments

`-task TaskName`

TaskName specifies the name of the task.

Feedback

`-item` *`ItemName`*

ItemName specifies the hierarchical name of the task item for which to get the page name",

Description

This command returns the name of the task page for the task item identified by the option values. This is useful when you want to create a new task item re-using a task page that is invoked by an existing task item.

Examples

To reuse the task page from the built-in task item "Pin Assignment->Pin Placement" in the task "Hierarchical Design" in your own task flow, you can do the following:

```
prompt> set pageName [gui_get_task_page -task "Hierarchical Design" \
                        -item "Pin Assignment->Pin Placement"]
prompt> gui_create_task_item -task myTask -name myItemName \
                        -page $pageName
```

See Also

- gui_create_task_item
- gui_set_current_task
- gui_get_task_list

---

gui_get_toolbar_names

Return a Tcl list of the names of all the toolbars that have been created with the *gui_create_toolbar* command.

Syntax

void *gui_get_toolbar_names* [-window *WindowId*]

`WindowId` *`String`*

Arguments

`-window` *`WindowId`*

Return toolbars defined in this window. If omitted, return toolbars defined in the active window.

Description

Return a Tcl list of the names of all the toolbars that have been created with gui_create_toolbar command for the specified window.

Feedback

See Also

- gui_create_toolbar
- gui_create_toolbar_item
- gui_delete_toolbar

- gui_show_toolbar

---

gui_get_user_widget_items

Get user widget items

Syntax

```
status gui_get_user_widget_items
[ -parent string ]
[ { -group string | -item string } ]
```

Arguments

`-parent string`

Specifies the optional parent collection or group.

If the command is run from an initialization tcl command or callback tcl command, then the parent is defaulted to the associated container.

`-group string`

Specifies the name of the group to return.

If the string '?' is specified, the command will return a list of allowed group names.

If the string '*' is specified, the command will return a collection of all groups.

`-item string`

Specifies the name of the item to return.

If the string '?' is specified, the command will return a list of allowed item names.

If the string '*' is specified, the command will return a collection of all items.

Description

This command returns a collection of existing user widget items.

Feedback

If no options are specified then all items are returned, if a group is specified then all items in the named group are returned, if an item is specified then just that item (if it exists) is returned.

Examples

The following example prints the value of the my_test item when the apply button is clicked in the created toolbar.

```
shell> proc buttonPressed { args } {
shell>   set item [gui_get_user_widget_items -name my_test]
shell>   echo "Value $value"
shell> }
shell> proc init_my_toolbar { args } {
shell>   gui_create_user_widget_group -name buttons -type flow {
shell>     set text [gui_create_user_widget_item -window $window -name
 text -type text]
shell>     set button [gui_create_user_widget_item -window $window -name
 button -type button]
shell>     set_attribute $button label "Apply"
shell>     set_attribute $button activated_proc buttonPressed
shell>   }
shell> }
shell> gui_create_window_toolbar_type -type my_toolbar -name "My Toolbar"
 \\·
shell>   -view_types Charts -command init_my_toolbar
shell> set window [gui_create_window -type $gui_default_window_type]
shell> set charts [gui_create_window -type Charts]
shell> gui_show_window_toolbar -window $charts
```

---

gui_get_utable

Get various state about User Table(s) [default: return list of all table names].

Feedback

Syntax

string *gui_get_utable*

```
-name           Table_Name
-has_name
-headers
-tag
-window         Window_name
-values         Column_Name
-bus_values     Column_Name
-rows
-parent
-filter
-columns

Table_Name      String
Window_Name     String
Column_Name     String
```

Arguments

`-name` *`Table_Name`*

A table name argument used with other argument switches below.

`-has_name`

Check if given table name given by the '-name' argument switch exist and return '1', else return '0'.

`-headers`

Get the table column headers for given table argument.

`-tag`

Get the table MetaData tag string for given table argument.

`-window` *`Window_Name`*

A UserTable window name argument used with other arguments below. If used alone it will return the current table name of the given window name.

`-values` *`Column_Name`*

Get the selected table cell value(s) in the given column for the given window argument. *Note*: Any column value(s) in the row of the selected cell(s) can be retrieved.

`-bus_values` *`Column_Name`*

Just like the '-values' option, except if the columns contain compressed bus values like 'bus*[*]*', then a list of values will be returned that match the glob expression.

Feedback

`-bus_values` *Column_Name*

Get the selected table cell bus values in the given column for the given window argument. If the table cell value is a compressed bussed value then all values are returned for that compressed value.

`-columns`

Get the selected table column name(s) for the given window argument.

`-rows`

Get the selected table row number(s) for the given window argument.

`-parent`

Get the parent table name for the given table name argument if it exists.

`-filter`

Get the filter expression for the current table shown in the given window name.

Description

```
This command allows you to get all current loaded UserTable names.
Other options allow you to get various other table state.
```

Examples

```
The following example check to see if the UserTable 'my_table' is
 currently loaded.

shell> if { [gui_get_utable -name my_table -has_name] } {
          echo "yes my_table is loaded"
       }

The following example looks for the 'full_name' column in the current
 active UserTable
and prints all the selected values in that column.
Note: If the table was a compressed table then using the option
 '-bus_values'
will return all the values for the compressed value.

shell> # Get the current active UserTable window:
       set win [gui_get_current_window -mru -type UserTable]
       # Get the table name in that window:
       set table [gui_get_utable -window $win]

       if { $table != {} } {
         # Get the selected column names in that table:
         set columns [gui_get_utable -window $win -columns]
         # If the column name 'full_name' is selected then list the
 values:
         if { [lsearch -exact $columns full_name] != -1} {
           set values [gui_get_utable -window $win -values full_name]
```

Feedback

```
            foreach v $values {
              echo "value: $v"
            }
          }
        }
```

---

gui_get_vm

Retrieves attributes for a specified visual mode.

Syntax

string *gui_get_vm*

```
-name identifier
[-buckets]
[-title]
[-help_topic]
[-infotip]
[-discrete]
[-icon_file]
[-update_cmd]
[-netfilter]
[-float]
```

Feedback

```
[-top_exaggeration]
[-mid_exaggeration]
[-bot_exaggeration]
[-show_only_pins_of_nets]
[-enable_bucket_delete]
```

Data Types

identifier string

Arguments

`-name` *identifier*

Specifies the name of the visual mode to be queried.

`-buckets`

Returns a list of bucket names. The bucket names are retrieved in rendering order, starting from the first to the last bucket rendered.

`-title`

Returns the title string.

`-help_topic`

Returns the help topic string.

`-infotip`

Returns the InfoTip string.

`-discrete`

Returns a true or false value that indicates whether the buckets of this visual mode are discrete or continuous. Only discrete buckets can be reordered. This attribute is set when this visual mode was created, and cannot be changed.

`-icon_file`

Returns the gui menu icon file.

`-update_cmd`

Returns the Tcl command that is executed when the visual mode is accessed. A typical use for this option is to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-netfilter`

Returns net connection filtering.

Feedback

`-float`

Returns a true or false value indicating whether the visual mode buckets have a floating point range.

`-top_exaggeration`

Returns the top bucket exaggeration.

`-mid_exaggeration`

Returns the middle bucket exaggeration.

`-bot_exaggeration`

Returns the bottom bucket exaggeration.

`-show_only_pins_of_nets`

Returns a true or false value that indicates whether the layout shows only pins of net objects in buckets.

`-enable_bucket_delete`

Returns a true or false value indicating whether the visual mode buckets can be deleted from context menu.

Description

The *gui_set_vm* command queries the option values of an existing visual mode.

Examples

To retrieve names of the buckets in the visual mode named "mycoloring1", use the following command:

```
prompt>gui_get_vm -name mycoloring1 -buckets
```

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_get_vmbucket
- gui_remove_vm
- gui_remove_vmbucket
- gui_set_vm
- gui_set_vmbucket
- gui_update_vm

Feedback

gui_get_vmbucket

Get attributes for Visual Mode Bucket

Syntax

string *gui_get_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip] [-netfilter] [-color] [-pattern] [-exaggeration] [-number] [-maxval] [-minval] [-visible] [-title] [-collection] [-objcount] [-gui_object]

```
string mode_identifier
string bucket_identifier
```

Arguments

`-vmname` *`mode_idnetifier`*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name` *`bucket_identifier`*

Specifies the name of the visual mode bucket to be queried. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-infotip`

Return infotip string.

`-netfilter` *`net_filter`*

Return net connection filtering.

`-color`

Return bucket rendering color.

`-pattern`

Return bucket rendering fill pattern.

`-exaggeration`

Return bucket min pixel exaggeration value.

`-number`

Return bucket display number.

`-maxval`

Return bucket maximum value.

Feedback

`-minval`

Return bucket minimum value.

`-visible`

Return visibility.

`-title`

Return bucket title.

`-collection`

Return object collection.

`-objcount`

Return the number of objects in the bucket.

`-gui_object`

Return gui object collection.

You can use this option only if you also use the *-collection* option.

Description

The gui_get_vmbucket command queries an instance of a visual mode bucket for the specified option values. The values are returned in a list of option-value pairs.

Examples

Query the current color for the bucket named "cat1" in the visual mode "foo":

shell> *gui_get_vmbucket -vmname foo -name cat1 -color*

Query the current color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> *gui_get_vmbucket -vmname foo -name cat1 -color -pattern*

---

gui_get_window_ids

Get a list of window ids

Syntax

```
ids gui_get_window_ids
[ -parent window_id ]
[ -type window_type ]
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-parent window_id`

Specifies the toplevel window id to get child view window ids from.

`-type window_type`

Specifies that the windows id returned should be restricted to those of the specified type.

Note: as a type can be only be associated with either a toplevel window or a child view window (not both) the type implies whether toplevel or child view window ids are returned.

If this option is not specified then either all toplevel window ids are returned (*-parent* option not specified) or all child view window ids of a specified toplevel window id are returned (*-parent* option specified).

Returns

ids

Returned list of window ids.

Description

This command gets a list of the ids of all toplevel windows, all toplevel windows of a specified type, all child view windows of a specified type, or all child view windows of a specified type in a specified toplevel window.

Feedback

Examples

The following example will create a toplevel window and a child layout window. Then this command will be used to retrieve the ids of the existing windows.

```
shell> set top [gui_create_window -type TopLevel]
shell> set cons [gui_create_window -type Layout -parent $top]
shell> set ids [gui_get_window_ids]   # return list containing values of
 $top and value of $cons.
shell> set childs [gui_get_window_ids -parent $top]   # return value of
 $cons.
shell> set layout_instances [gui_get_window_ids -type Layout] # return
 value of $cons.
```

gui_get_window_pref_categories

Get list of preference categories for object specified by window

Syntax

```
categories gui_get_window_pref_categories
{ -window window_id | -window_type window_type }
```

Data Types

```
window_id       string
window_type     string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

Feedback

`-window_type` *`window_type`*

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

Returns

categories

The returned preference categories.

Description

This command retrieves the list of preference categories for a window or window type.

Examples

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_categories -window TopLevel.1]
```

gui_get_window_pref_keys

Get list of preference categories for object specified by window

Feedback

Syntax

```
categories gui_get_window_pref_keys
{ -window window_id | -window_type window_type }
[ -category category ]
```

Data Types

```
window_id       string
window_type     string
category        string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

`-category category`

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

Returns

categories

The returned preference categories.

Description

This command retrieves the list of preference categories for a window or window type.

Examples

The following example gets the preference categories for the TopLevel.1 window.

```
shell> ser cats [gui_get_window_pref_keys -window TopLevel.1]
```

See Also

---

gui_get_window_pref_value

Get preference value for object specified by window or window type

Syntax

```
value gui_get_window_pref_value
{ -window window_id | -window_type window_type }
[ -category category ]
-key key
```

Data Types

```
window_id       string
window_type     string
category        string
key             string
```

Arguments

`-window window_id`

Specifies the name of the window that the preference will be retrieved from. This option is mutually exclusive with the -window_type option.

`-window_type window_type`

Specifies the name of the window type that instances of the type will have the preference be retrieved from. This option is mutually exclusive with the -window option.

Feedback

`-category` *category*

Specifies the category to search for the key. If not specified, a default category will be used.

`-key` *key*

Specifies the key to retrieve the value from.

Returns

value

The value of the key.

Description

This command retrieves the value of a preference key from the specified key name and category of the specified window or window type. If a preference is set on a window type, then all instances of that type will inherits the preference, so the value can be set on a type and retrieved from any instance of that type (or derived from that type).

Examples

The following example creates a preference for a window and then uses the *gui_get_window_pref_value* command to retrieve the value for the preference.

```
shell> gui_set_window_pref_key -window Console.1 -key test -value_type
 integer -value 201
shell> set x [gui_get_window_pref_value -window Console.1 -key test]
shell> if {$x == 201} { echo "success" }
```

- gui_exist_pref_key
- gui_update_pref_file

---

gui_get_window_presets

Gets list of preset name for object specified by window_type

Syntax

```
string gui_get_window_presets
-window_type window_type
[-system]
[-shared]
```

Data Types

```
window_type    string
```

Arguments

`-window_type window_type`

Specifies the name of the window type that the presets be retrieved from.

`-system`

Return system presets. This option is mutually exclusive with the -shared option.

`-shared`

Return shared presets. This option is mutually exclusive with the -system option.

Description

This command retrieves the list of presets for a window type. This command has been deprecated, please use gui_get_presets instead.

Examples

The following example gets the system presets for the Layout.

```
prompt> gui_get_window_presets -window_type Layout -system
```

See Also

- gui_get_presets
- gui_set_preset
- gui_set_window_preset

Feedback

gui_get_window_types

Get a list of window types

Syntax

```
types gui_get_window_types
[ -type token ]
```

Data Types

```
token    string
```

Arguments

`-type window_types`

Specifies whether to return toplevel windows ('toplevel') or child view windows ('child').

If toplevel window types are specified then the first type is guaranteed to be the default toplevel window type.

Returns

types

Returned list of window types.

Description

This command returns a list of existing window types. Instances of these types can be instantiated with the *gui_create_window* command. The returned list can be restricted to just toplevel windows or child view windows by specifying the *-type* option.

Examples

The following examples illustrate some usages of the command.

```
shell> gui_get_window_types
shell> gui_get_window_types -type toplevel
shell> gui_get_window_types -type child
```

See Also

- gui_set_active_window
- gui_get_current_window

---

gui_group_charts_plots

Group plots in charts view

Syntax

```
status gui_group_charts_plots
-view view_name
[ -x1x2 ]
[ -y1y2 ]
[ -overlay ]
[ plots ]
```

Data Types

```
view_name     string
plot_id_list  list
```

Arguments

`-view view_name`

Charts View to group.

`-x1x2`

This option specifies that two plots are connected such that they have a shared y axis range but two independent x axes ranges.

If the *-overlay* option is used then the two plots are overlaid and the X axis of the first plot is placed on the bottom and the X axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results horizontal stacking is recommended so the shared y axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-y1y2* option.

`-y1y2`

This option specifies that two plots are connected such that they have a shared x axis range but two independent y axes ranges.

Feedback

If the *-overlay* option is used then the two plots are overlaid and the Y axis of the first plot is placed on the bottom and the Y axis of the second plot is placed on the top. Note: To ensure the plots are overlaid correctly the two plots are forced to the same area of the view (usually the whole view).

If the *-overlay* option is not used then the two plots are not overlaid and can be placed anywhere in the view. For best results vertical stacking is recommended so the shared x axes are placed next to each other.

There must be exactly two plots specified to the *-plots* option.

This option cannot be combined with the *-x1x2* option.

`-overlay`

This option specifies that the plots have shared x and/or y ranges and are drawn on top of each other so they can share a single key and title.

If the *-x1x2* or *-y1y2* option are specified then only the x or y axis range is shared (See descriptions of these options above).

If neither of the *-x1x2* or *-y1y2* options are specified then both the x and y axis ranges are shared. In this case two or more plots can be specified.

`plots`

List of plots to group.

For *x1x2* or *y1y2* options this must be two plots. For *-overlay* option, without the *x1x2* and *y1y2* options, this must be two or more plots.

Description

Group related plots in a view.

Grouped plots can share x or y axis ranges and can be overlaid.

Sharing x and/or y axis is useful when you want to compare data across two plots. Overlay is useful when you want to display multiple plot types with the same data e.g. a combined barchart and xy plot (line plot).

Examples

The following example groups two plots so they are overlaid and share a common x axes.

```
shell> gui_group_charts_plots -view $view -y1y2 -overlay -plots [list
 $plot1 $plot2]
```

See Also

- gui_create_charts_plot

Feedback

gui_hide_palette

Hides the specified palette.

Syntax

```
status gui_hide_palette
{ -name palette_id | -type palette_type | -all }
[ -parent window_id ]
```

Data Types

```
palette_id    string
palette_type  string
window_id     string
```

Arguments

`-name palette_id`

Specifies the palette name id or title.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this name in all toplevel windows are hidden.

This option precludes the *-type* and *-all* options.

`-type palette_type`

Specifies the palette type id. Any matching palette of this type will be hidden.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes of this type in all toplevel windows are hidden.

This option precludes the *-name* and *-all* options.

`-all`

Hides all palettes.

If the *-parent* option is specified, only palettes in the specified parent toplevel window are hidden. If the *-parent* option is not specified, all palettes in all toplevel windows are hidden.

This option precludes the *-name* and *-type* options.

`-parent window_id`

Specifies the parent toplevel window to hide the palette type in.

Note: this option is only applicable if the *-type* option is specified.

Feedback

Description

This command hides the specified palettes.

Examples

The following example hides all Layer palettes:

```
shell> gui_hide_palette -type Layout
```

See Also

- gui_show_palette

---

gui_hide_toolbar

Hides the specified toolbar or all the toolbars in the specified window or for a window type.

Syntax

void *gui_hide_toolbar*

```
-toolbar tool_bar_name | -all
[-window window_id]
[-window_type window_type]
```

Data Types

```
tool_bar_name      string
window_id          string
window_type        string list
```

Arguments

`-toolbar tool_bar_name`

Specifies the toolbar you want to hide. The *-toolbar* option and the *-all* option are mutually exclusive.

`-all`

Hides all the toolbars in the specified window. The *-all* option and the *-toolbar* option are mutually exclusive.

`-window window_id`

Specifies the window in which you want to hide the specified toolbar or all toolbars. This option is mutually exclusive with the *-window_type* option. If both *-window* and *-window_type* options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

Feedback

`-window_type` *`window_type`*

Specifies the window types in which you want to hide the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the *-window* option. If both *-window* and *-window_type* options are omitted, then by default the tool hides the toolbar or toolbars in the active window.

Description

This command hides either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or in all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by *gui_show_toolbar* will be saved and restored on next invocation of the tool if save and restore has not been disabled.

Examples

The following example hides the File toolbar in the active window:

```
prompt> gui_hide_toolbar -toolbar File
```

The following example hides all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_hide_toolbar -all -window LayoutWindow.1
```

The following example hides the File toolbar in all TimingWindow type windows:

```
prompt> gui_hide_toolbar -all -window_type TimingWindow
```

The following example hides all the toolbars in all window types:

```
prompt> gui_hide_toolbar -all -window_type [gui_get_window_types -type
 toplevel]
```

---

gui_hide_window_toolbar

Hide toolbar in view

Syntax

```
status gui_hide_window_toolbar
-window window_id
[-toolbar toolbar]
```

Data Types

```
window_id  string
toolbar  string
```

Arguments

`-window window_id`

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-toolbar toolbar`

Specifies the toolbar to hide.

Description

This command hides the specified view's toolbar.

Examples

The following example will show a Charts View, show and hide the toolbar.

```
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
shell> gui_show_window_toolbar -window $charts
shell> gui_hide_window_toolbar -window $charts
```

See Also

- gui_create_window
- gui_show_window_toolbar

Feedback

gui_highlight_nets_of_selected

Highlight the nets of the selected object in the current highlight color.

Syntax

```
status gui_highlight_nets_of_selected
[-flylines]
```

Arguments

`-flylines`

Specifies that the net should always be displayed on the layout using flylines, even if it is routed.

Description

The *gui_highlight_nets_of_selected* command highlights the nets of the objects currently selected in the GUI. Typically this is used in conjunction with the Layout view to view the highlighted nets, and is accessed via the Highlight menu item on the Layout Window. This command adds to any existing highlights and the highlighting will remain until cleared by the user or the objects referenced in the highlight are removed. If no objects are selected this command will not do anything.

The layout view renders the net using its routing if the net has routing, and if it does not the net is rendered using a flyline. However if the -flylines option is specified the layout will always render the highlighted net using the flylines between its pins.

Examples

Highlight the nets of the selected objects.

```
prompt> gui_highlight_nets_of_selected
```

See Also

- gui_change_highlight
- change_selection

gui_import_utable

Create a UserTable and import records from a value file or a report.

Syntax

string *gui_import_utable*

```
-file           File_Name [-tsv_mode] [-ssv_mode]
[-name          Table_Name]
```

Feedback

```
[-tsv_mode]
[-ssv_mode]
[-fold]
[-report_type    Report_Type_Name]
[-meta_obj       MetaObj_Name]
[-replace]

Table_Name            String
File_Name             String
Report_Type_Name      String
MetaObj_Name          String
```

Arguments

`-file File_Name`

The name of the CSV value file from which to import and fill the user table with.

`-name Table_Name`

The name for the user table created. By default, the name takes the name of the file minus the extension.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-fold`

This flag causes extra row data past the number of columns specified to fold into the last column. The default is to discard extra data.

`-report_type`

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

`-meta_obj MetaObj_Name`

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-replace`

Optional flag that will replace the given table name, if it already exists, with the imported table data.

Feedback

Description

```
This command creates a new UserTable in memory and imports the data from
 a CSV/TSV/SSV
value file. The name of the table will take the base name of the file
 unless a name is
provided.

The first line of the file is assumed to be a header line that defines
 the column names.
In addition, column names can have postfixes that describe the data
 format of that column.

Supported column name postfixes are:

  :string
  :int
  :double
  :cell
  :net
  :port
  :pin
  :point
  :endpoint
  :file
```

Examples

```
The following example creates a new UserTable called 'data' and imports
 the values from
the CSV file 'data.csv'.

shell> gui_import_utable -file data.csv

The following example creates a new UserTable, names it 'my_table' called
 'data' and
imports the values from the CSV file 'data.csv'. It also instructs the
 import to fold
any extra data found in the row into the last column defined.

shell> gui_import_utable -file data.csv -name my_table -fold
```

---

gui_list_attrgroups

Lists attribute group information for a specified object type or all object types.

Syntax

```
status gui_list_attrgroups
-class design_object
-name name
[-all]
[-tcl]
[-full]
[-attr_list]
```

Data Types

```
design_object       string
name                string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the name of the attribute group to be listed for the specified object type or for all object types.

`-all`

Lists the attribute groups for all object types. This option and the -class option are mutually exclusive.

`-tcl`

Lists the attribute group information in a tool command language (Tcl) format that is suitable for Tcl processing.

Feedback

`-full`

Specifies the full Tcl output format, which reports all possible group information.

`-attr_list`

Lists attributes only.

Description

The *gui_list_attrgroups* command lists attribute group information for the specified object type or for all object types. Use the *-tcl* option to get results that are suitable for Tcl processing.

Examples

```
prompt> gui_list_attrgroups -class Cell -tcl
"Hierarchy" "Edit"

prompt> gui_list_attrgroups -class Cell -name "Hierarchy" -tcl -attr_list
{Name} {Hierarchical} {Owning Cell} {isPhysConstraint} {Hard Macro} ...
 {FullName}

prompt> gui_list_attrgroups -all -tcl
Cell {  "Hierarchy" "Edit" }  Net {  "Timing" }  Pin {  "Timing" }

prompt> gui_list_attrgroups -class Cell -tcl -attr_list
{ "Hierarchy" { {Name} {Hierarchical} {Owning Cell} ...{FullName} } }
{ "Edit" { {Name} {isPhysConstraint} {Orientation} ... {FullName} } }

prompt> gui_list_attrgroups -class Cell
Cell, "Hierarchy", { {Name} {Hierarchical} {Owning Cell}
 {isPhysConstraint} ... }  ;
Cell, "Edit", { {Name} {isPhysConstraint} {Orientation} {Location} ... }
  ;
The fields displayed above are in the following order:
Class, Group Name, Attributes list;
```

---

gui_list_category_rules

Lists all category rules except built-in rules by default.

Feedback

Syntax

list *gui_list_category_rules*

```
[-all | -names rule_names_list]
[-format script | tcl_list]
```

Data Types

```
rule_names_list    list
```

Arguments

`-all`

Lists all category rules, including built-in rules.

This option and the *-names* option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

`-names rule_names_list`

Specifies the names of the category rules to be listed.

This option and the *-all* option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

`-format script | tcl_list`

Specifies the output format in which the category rules are listed. The default output format is *script*.

When the *script* format is used, the category rules are listed as a Tool Command Language (Tcl) script of *gui_create_category_rule* commands that you can replay. In this case, the rules are streamed to the output stream. You can redirect the output by using the *redirect* command, for example, if you want to capture the script output in a file to use again later. When the *script* format is used, the command result is an empty string.

If the *tcl_list* format is specified, the category rules are listed in an "array set compatible" Tcl list format. In this case, the command result is a Tcl list.

Description

This command lists category rules that have already been created by the *gui_create_category_rule* command during the current run of the tool.

When you run this command without specifying either the *-all* option or the *-names* option, the command lists all category rules except built-in rules. Specify the *-all* option to list all category rules, including the built-in rules. Specify the *-names* option to list individual rules by name.

Feedback

Examples

The following example lists all category rules, including the built-in rules:

```
prompt> gui_list_category_rules -all
gui_create_category_rule  -name Pathgroups  -builtin \\
  -category <path_group.full_name>
gui_create_category_rule  -name Session  -builtin \\
  -category <session_name>
gui_create_category_rule  -name {Path Type}  -builtin \\
  -category <path_type>
  ...
  ...
```

The following example lists all category rules except the built-in rules:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> gui_list_category_rules
gui_create_category_rule  -name rule1 \\
  -category <session_name>
gui_create_category_rule  -name rule2 \\
  -category <path_group.full_name>
```

The following example redirects the script output to a file that you can source during a subsequent run of the tool:

```
prompt> redirect -file /remote/dir1/rules.tcl {gui_list_category_rules}
prompt>
```

The following example uses the *-names* option to list only the rules named rule1 and rule3:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> gui_create_category_rule  -name rule3 -category
 <startpoint.full_name>
rule3
prompt> gui_list_category_rules -names {rule1 rule3}
gui_create_category_rule  -name rule1 \\
  -category <session_name>
gui_create_category_rule  -name rule3 \\
  -category <startpoint.full_name>
```

Feedback

The following example uses the *tcl_list* output format to query the category specification of the rule named rule1:

```
prompt> gui_create_category_rule  -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule  -name rule2 -category
 <path_group.full_name>
rule2
prompt> array set rules [gui_list_category_rules -format tcl_list]
Information: Defining new variable 'rules'. (CMD-041)
prompt> array set rule1_options $rules(rule1)
Information: Defining new variable 'rule1_options'. (CMD-041)
prompt> set rule1_cat_spec $rule1_options(category)
Information: Defining new variable 'rule1_cat_spec'. (CMD-041)
<session_name>
```

gui_list_vm

List Current Visual Modes

Syntax

string *gui_list_vm*

Description

The gui_list_vm command will return a list of existing visual modes.

Examples

To get the names of all available visual modes, use the following command:

shell> *gui_list_vm*

See Also

- gui_set_vmbucket
- gui_update_vm

---

gui_load_area_net_connection_vm

Loads data for the Net Connection in Area visual mode.

Syntax

```
status  gui_load_area_net_connection_vm
-area {llx lly urx ury}
[-type {power ground clock signal tie_high tie_low}]
[-hier]
```

Data Types

```
llx  float
lly  float
urx  float
ury  float
```

Arguments

`-area {llx lly urx ury}`

Specifies the area to analyze for net connectivity.

`-type {power ground clock signal tie_high tie_low}`

Specifies one or more types of nets to show. Possible types are power, ground, clock, signal, tie_high, and tie_low. This option takes types as a list of strings.

`-hier`

Specifies that the analysis should include subhierarchies. If this option is not specified, the tool analyzes only nets in the current top-level design.

Description

The command generates visual mode of net connections in the specified area. Net connections are categorized as follows:

- local connection: Nets have all their pins within the specified area.
- global connection: nets have at least one pin outside of the specified area, and one pin inside of specified area.
- path-through connection: nets have all their pins outside of specified area.

Feedback

Nets in the visual mode are displayed based on layout view setting of net.

Examples

The following example shows clock and signal types of net connections in the specified area.

```
prompt> gui_load_area_net_connection_vm -area \\
   {550.710 1840.430 1247.100 2150.640} -type {clock signal}
```

---

gui_load_cell_density_mm

Loads the data for cell density map mode.

Syntax

```
status  gui_load_cell_density_mm
[-area area]
```

Data Types

area	list

Arguments

`-area` *area*

Analyzes area for cell density. If area is not given, the default area is whole design area.

Description

The command generates the map mode view of cell density in a given area. Each grid is colored based on the percentage of occupied area of cells in the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows cell density in the specified area.

```
prompt> gui_load_cell_density_mm -area \\
{284.820 390.670 1202.790 954.120}
```

---

gui_load_cell_displacement_vm

Loads the cell displacement visual mode data

Feedback

Syntax

```
string gui_load_cell_displacement_vm -file String
[-bin_on_direction]
[-num_bins integer]
[-bin_range float]
[-lower_bound float]
[-lower_bound_strict]
[-upper_bound float]
[-upper_bound_strict]
[-hier]
[-threshold float]
[-cells string]
```

Data Types

```
String  string
integer int
float   double
string  string
```

Arguments

`-file String`

Specifies the cell location reference file name.

`-bin_on_direction`

Uses binning on direction.

`-num_bins integer`

Specifies the number of bins to show.

`-bin_range float`

Specifies the displacement value range per bin.

`-lower_bound float`

Specifies the lower bound of binning.

`-lower_bound_strict`

Uses the lower bound as strict bound. Values below the lower bound are ignored.

`-upper_bound float`

Specified the upper bound of binning.

`-upper_bound_strict`

Uses the upper bound as strict bound. Values above the upper bound are ignored.

Feedback

`-hier`

Enables hierarchy support

`-threshold` *`float`*

Specifies the displacement threshold for analysis.

`-cells` *`string`*

Specifies the cells for analysis

Description

The command generates the visual mode view of cell displacement.

Examples

The following example shows all the cells based on the distance of displacement.

```
prompt> gui_load_cell_displacement_vm -file myfile.cref -num_bins 6
 -threshold 10000
```

See Also

- gui_write_cell_location

---

gui_load_cell_slack_vm

Loads the data for cell slack visual mode.

Syntax

```
status  gui_load_cell_slack_vm
[-scenario scenario]
[-analysis approach]
[-num_bins count]
[-bin_range range]
[-lower_bound value]
[-lower_bound_strict]
[-upper_bound value]
[-upper_bound_strict]
[-cells cell_list]
[-color_scheme scheme]
```

Data Types

```
scenario        string
approach        string
count           integer
range           float
value           float
```

Feedback

```
cell_list       list
scheme          string
```

Arguments

`-scenario` *scenario*

Specifies the scenario for the visual mode. By default, current scenario is used.

`-analysis setup | hold`

Specifies the analysis approach for the visual mode. The alternatives are setup and hold. By default, the analysis approach is setup.

`-num_bins` *count*

Specifies the number of bins to create.

`-bin_range` *range*

Specifies the range of each bin to create when the number of bins is not specified.

`-lower_bound` *value*

Specifies the lower bound value for the bins. Values below this bound are placed in a separate bin.

`-lower_bound_strict`

Uses the lower bound as an exact minimum limit on the bound. Values below the lower bound are ignored.

`-upper_bound` *value*

Specifies the upper bound value for the bins. Values above this bound are placed in a separate bin.

`-upper_bound_strict`

Uses the upper bound as an exact maximum limit on the bound. Values above the upper bound are ignored.

`-cells` *cell_list*

Specifies the cells to be used in the visual mode. If this option is not specified, all the cells in the design are used by default.

`-color_scheme temperature | gradient`

Specifies the bucket coloring approach in the visual mode. The alternatives are temperature scale and gradient. By default, the color scheme is temperature scale.

Feedback

Description

The command generates the visual mode view of cell slack. Each cell is colored based on the color of the bin it falls into.

Examples

The following example will place all the cells in the design into 8 bins.

```
prompt> gui_load_cell_slack_vm -num_bins 8 \\
-lower_bound 0
```

The following example will place all the currently selected cells into 8 bins.

```
prompt> gui_load_cell_slack_vm -num_bins 8 \\
-lower_bound 0 -cells [get_selection] -scenario [current_scenario]
```

---

gui_load_clock_trunk_planning

Starts a GUI clock trunk planning session.

Syntax

gui_load_clock_trunk_planning

```
[-clocks clocks]
[-include_generated]
[-self]
[-show_timing_flylines]
```

Data Types

clocks list

Arguments

`-clocks` *clocks*

Specifies the clocks to plan. By default, planning is performed for all clocks and all virtual clocks and generated clocks are skipped.

`-include_generated`

Includes generated clocks when get auto clocks. This option should not be used with the *-clocks* option.

`-self`

Ignore master clock portion for generated clock.

`-show_timing_flylines`

Generates data for timing flylines. This option requires a timing update.

Feedback

Description

This command starts a clock trunk planning session for a given clock. To view the clock trunk in the layout window, open the GUI clock trunk planning flylines tool. The flylines tool identifies the clock trunk and displays the clock trunk annotations in the layout.

The clock trunk is identified as follows:

- The clock source pins are part of the clock trunk.
- If a certain pin is part of the clock trunk, then all pins on all paths from the clock source pin to that certain pin are implicitly part of the clock trunk
- All user-defined clock trunk endpoints are part of the clock trunk.
- All first-level block conns/ports are part of the clock trunk, unless there is already a user-defined clock trunk endpoint upstream (for example, somewhere on all paths from the clock root to here).
- For all pins in the clock trunk which have less than *fanout_limit* number of fanouts, the tool recursively adds fanout. However this is not done for clock-trunk leafs that are a user-defined clock trunk endpoint or a first-level block conn/port. (Note that nonleafs which fall into these categories are still expanded).
- The leaf pins of the resulting clock trunk are called clock trunk end points.

Examples

Start a planning session on all clocks which enter some block.

```
prompt> gui_load_clock_trunk_planning
```

Start a planning session for clock CLK.

```
prompt> gui_load_clock_trunk_planning -clock CLK
```

See Also

- create_clock_buffer
- set_clock_trunk_endpoints
- synthesize_clock_trees

---

gui_load_hierarchy_vm

Loads the data for hierarchy visual mode.

Feedback

Syntax

```
status  gui_load_hierarchy_vm
[-clear]
[-level level]
[-objects object_list]
[-hierarchical]
```

Data Types

```
level        integer
object_list  list
```

Arguments

`-clear`

Removes the coloring from all hierarchy levels.

`-level level`

Colors all the cells at a particular hierarchy level.

`-objects object_list`

Colors specific hierarchy objects. If objects are not provided, the tool colors cells in the entire design. if *plan.place.hierarchy_by_name* is *true*, the option accepts flat hier name bound objects.

`-hierarchical`

Specifies that subhierarchies are included in the analysis. If this option is not specified, the tool analyzes only cells in the current top-level design.

Description

This command loads the data for hierarchy visual mode. The hierarchy visual mode provides a high-level view of the placement quality of logic blocks and hierarchical cells in your physical design. This visual mode can be used to color all the cells on a particular hierarchy level or just the specified hierarchical cells.

Examples

The following example clears the hierarchy visual mode.

```
prompt> gui_load_hierarchy_vm -clear
```

The following example colors all the cells at hierarchical level 2.

```
prompt> gui_load_hierarchy_vm -level 2
```

The following example colors all the objects in the selection.

```
prompt> gui_load_hierarchy_vm -objects [get_selection]
```

Feedback

gui_load_imported_path_pins_vm

Loads the data for imported path pins visual mode.

Syntax

```
status  gui_load_imported_path_pins_vm
[-timing_report file_name]
[-timing_text report_text]
[-draw_path path_type]
[-from path_number]
[-to path_number]
[-clear]
```

Data Types

```
file_name           string
report_text         string
path_type           string
path_number         integer
```

Arguments

`-timing_report file_name`

Generates the imported path pins visual mode from the timing report file. The file could be plain text or compressed(.gz).

`-timing_text report_text`

Generates imported path pins visual mode from the timing report text.

`-draw_path path_type`

Specifies the type to draw the path. The type value can be routes, flylines or both. The defult value is flylines. When specifies routes or both, the timing report should include input pins.

`-from path_number`

Generates imported path pins visual mode start from the specified path number.

`-to path_number`

Generates imported path pins visual mode ends with the specified path number.

`-clear`

Removes coloring from all pins and flylines.

Description

Loads the data for imported path pins visual mode. After importing timing path data from a timing report, the visual mode shows pins and the connectivity in one or more timing paths

Feedback

in Layout window. This visual mode colors the pins and flylines with a different color for each imported timing path.

Examples

The following example will load the timing report file "/remote/misc16/timing_report" to generate the imported path pins visual mode.

```
prompt> gui_load_imported_path_pins_vm \\
  -timing_report "/remote/misc16/timing_report"
```

---

gui_load_path_analyzer_flylines

Loads the data for path analyzer flylines palette.

Syntax

```
status gui_load_path_analyzer_flylines
```

Data Types

None

Arguments

None

Description

The command generates the flylines data of path analyzer palette. Each timing path flyline is colored based on either its connection count in connection mode, or its timing effort in timing mode.

Examples

The following example reloads the timing path flylines data in the design.

```
prompt> gui_load_path_analyzer_flylines
```

---

gui_load_pin_density_mm

Loads the data for pin density map mode.

Syntax

status *gui_load_pin_density_mm*

[-area *area*]

Feedback

Data Types

```
area   list
```

Arguments

```
-area area
```

Area to be analyzed for pin density. By default, the command uses the entire design area.

Description

The command generates map mode view of pin density in a given area. The grids are colored based on the number of pins within the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows pin density in the specified area.

```
prompt> gui_load_pin_density_mm -area \\
  {284.820 390.670 1202.790 954.120}
```

---

gui_load_power_density_mm

Loads the data for power density map mode.

Syntax

```
status  gui_load_power_density_mm
[-area {{x1 y1} {x2 y2}} ]
-scenario scenario_name
```

Data Types

```
x1             float
y1             float
x2             float
y2             float
scenario_name  string
```

Arguments

```
-area {{x1 y1} {x2 y2}}
```

Limits the report scope to the specified area. This argument is optional. By default, the entire design area is used.

Feedback

`-scenario`

Specifies the scenario to be reported. This option is required.

Description

This command generates the data for the power density map mode. The design layout area, or user specified area, is split into grids. The grids dimension is set in the mapmode panel. The power contribution for cells that intersect the grid is proportional to the area within each grid sector.

Multicorner-Multimode Support

This command performs its analysis for specified scenario. The *-scenario* argument is required.

Examples

The following example reloads the power density map mode data from the "default" scenario.

```
prompt> gui_load_power_density_mm -scenario default
```

The following example reloads the power density map mode data within the specified area from the "sc1.BC" scenario.

```
prompt> gui_load_power_density_mm -scenario sc1.BC -area { {10.5 0.50}
 {300.0 129.80} }
```

---

gui_load_routing_guide_vm

Loads the data for routing guides by type visual mode.

Syntax

```
status  gui_load_routing_guide_vm
-types type_list
[-hierarchical]
```

Data Types

type_list list

Arguments

`-types` *type_list*

Specifies the types of routing guide to load in the visual mode. This option is required. The supported types are:

```
access_preference
default
```

Feedback

```
   design_boundary_blockage
   forbidden_preferred_grid_extension
   max_patterns
   metal_cut_allowed
   pin_access
   river_routing
   single_row_via_ladder_pattern_must_join_allowed
   standard_cell_region
   switched_direction_only
```

`-hierarchical`

Searches for routing guides level-by-level relative to the current instance. if this option is not specified, the tool loads only routing guide in the current top-level design.

Description

The command generates the visual mode view of routing guide. Each routing guide is colored based on its type.

Examples

The following example will color routing guides which type is access_preference or metal_cut_allowed.

```
prompt> gui_load_routing_guide_vm -types {access_preference
 metal_cut_allowed}
```

---

gui_load_rp_group_net_connectivity_vm

Loads the data for the relative placement (RP) net connection visual mode.

Syntax

```
status  gui_load_rp_group_net_connectivity_vm
-clct rp_group_collection
[-type {clock signal}]
```

Data Types

rp_group_collection collection

Arguments

`-clct` *rp_group_collection*

Specifies the collection of RP groups to load.

`-type {clock signal}`

Specifies the types of nets to show. Valid signal types are *clock* and *signal*. This option takes the types as a list of strings.

Feedback

Description

This command generates visual mode of net connections of a specified RP group collection. Net connections are categorized as follows:

- local connection: Nets that only connect to cells inside the RP group collection.
- global connection: Nets that connect to the cells outside the given RP group collection.

  Nets in the visual mode are displayed based on the layout view setting of net.

Examples

The following example shows signal net connections for the RP group collection name test1.

```
prompt> gui_load_rp_group_net_connectivity_vm -type {signal} \\
   -clct [get_rp_groups {test1}]
```

See Also

- add_to_rp_group
- create_rp_group
- get_rp_groups
- remove_from_rp_group
- remove_rp_groups

---

gui_load_rp_vm

Loads the data for relative placement (RP) group visual mode.

Syntax

```
status  gui_load_rp_vm
[-color group | hierarchy]
[-num_colors count]
[-cell_only]
```

Data Types

```
count           integer
```

Arguments

`-color group | hierarchy`

Specifies whether to color objects by relative placement group or relative placement hierarchy level.

Feedback

`-num_colors` *count*

Specifies the number of colors to be used in the visual mode.

`-cell_only`

Colors cells inside the RP group only.

Description

This command loads the data for relative placement (RP) visual mode. Relative placement visual mode helps to examine the placement of the instances (cells and other RP groups) in each group. This visual mode displays a colored map of RP groups with a different color either for each group (by default) or for each relative placement hierarchy level.

Examples

The following example uses 11 colors to color the cells based on relative placement groups.

```
prompt> gui_load_rp_vm -color group \\
-num_colors 11 -cell_only
```

---

gui_load_scan_chain_vm

Loads the data for scan chain visual mode.

Syntax

```
status  gui_load_scan_chain_vm
-chains scan_chain_names_list
```

Data Types

scan_chain_names_list	list

Arguments

`-chains` *scan_chain_names_list*

Loads the list of scan chains into the visual mode.

Description

Loads the data for scan chain visual mode. This visual mode can be used to examine the placement of scan cells in the design after a scan is inserted. This visual mode colors each scan chain with a different color.

Note that the cell count reported by this command includes all cell objects along the scan path.

Feedback

Examples

The following example displays the scan chains 1, 2, and 3.

```
prompt> gui_load_scan_chain_vm -chains {1 2 3}
```

---

gui_load_voltage_area_vm

Loads the data for voltage area visual mode.

Syntax

```
status  gui_load_voltage_area_vm
```

Description

The command generates the visual mode view of voltage areas. Each voltage area is colored based on its type.

Examples

The following example will place all the voltage areas in the design into different bins based on their types.

```
prompt> gui_load_voltage_area_vm
```

---

gui_log_performance

Controls the start and stop of a performance data logging process and outputs into a file.

Syntax

```
string gui_log_performance
[-start file_name|-stop]
[-compress]
[-quiet]
```

Data Types

```
file_name          string
```

Arguments

`-start file_name`

This option is mutually exclusive with -stop. The argument is the path name of the file to which the log is output. The option begins logging performance data. If the file already exists, the command overwrites the existing file.

Feedback

`-stop`

This option is mutually exclusive with -start. This option stops logging performance data. After stopped, the log cannot be reopened for appending.

`-compress`

If given, the log is saved as a compressed file. This option must be combined with -start.

`-quiet`

If given, this option causes the command to ignore error conditions.

Description

This command controls the start and stop of a performance data logging process. The performance data is logged before and after executing the commands which are required. The data includes cpu, memory and time. After successfully start a log, the command returns the path name with extension .log or .log.gz if not given in *file_name*.

Examples

```
Start logging and save the log to a file without compressing.

prompt> gui_log_performance -start ./test
/an/absolute/path/.test.log

Start logging and save the log to a compressed file.

prompt> gui_log_performance -start ./test -compress
/an/absolute/path/.test.log.gz

Stop logging

prompt> gui_log_performance -stop
```

---

gui_merge_utable

Merge 2 (loaded) tables via the given join column(s).

Syntax

string *gui_merge_utable*

```
-name             Table_Name
-merge_table      Table_Name
-join_columns     Column_Names
[-output_table    Table_Name]
[-columns         Column_Names]

Table_Name       String
Column_Names     List of Strings
```

Feedback

Arguments

`-name` *`Table_Name`*

A primary table name to merge into unless an output table name is also given.

`-merge_table` *`Table_Name`*

The merge table name. This table must have the same 'join columns' as the primary table.

`-join_columns` *`Column_Names`*

The join columns can be one or more columns that provide a unique key that only matches one row at a time. This usually is a full object name like a net,port or cell name, but can also be a 'key set' like a full_name plus object_class.

`-output_table` *`Table_Name`*

An *optional* output table name where the resultant merged table is stored, default is the primary table.

`-columns` *`Column_Names`*

An *optional* merge column list of columns that specify the columns to merge from the merge table, default is all.

Description

This command allows you to merge two loaded tables with a common set of (key/join) columns and produces a resultant merged table that can be saved under a new table name or by default, will be saved in the original primary table. Both tables have to be loaded in memory, see links for gui_import_utable and gui_open_utable below to read in tables.

Examples

The following example merges two tables (tableA & tableB) joining them via the common key columns (full_name & object_class) and then outputs the result into tableC. It also only merges the column 'power' from tableB with all of tableA, by default all columns in tableB would be merged.

```
shell> # Import tableA:
       gui_import_utable -file tableA.csv
       # Import tableB:
       gui_import_utable -file tableB.csv

       # Merge them into a new tableC
       gui_merge_utable -name tableA -merge tableB -output tableC \\
            -join_columns {full_name object_class} -columns {power}

       # View merged tableC:
       gui_show_utable -name tableC
```

---

gui_mouse_tool

Operate mouse tools of a given view

Syntax

gui_mouse_tool

-window *window* [-start *tool* | -current | -list | -add_point *{x y}* | -add_relative_point *{x y}* | -at_point *{x y}* | -drag *{{x1 y1} {x2 y2}}* | -delete_point | -apply | -reset | -cancel | -cycle | -cycle_back | -modifiers *{Shift Control Alt}* | -scale *double*]

```
window          String
tool            String
```

Arguments

`-window` *window*

window specifies the window of which this command should operate the mouse tool.

`-start` *tool*

Starts the given mouse tool.

`-current`

Return the name of current active tool.

`-list`

Return the names of all available tools.

`-add_point` *{x y}*

Add an input point.

`-add_relative_point` *{x y}*

Add a relative point.

Feedback

`-at_point {x y}`

Add a point.

`-drag {{x1 y1} {x2 y2}}`

Perform drag operation between two points.

`-delete_point`

Removes last input point.

`-apply`

Performs tool action.

`-reset`

Clears all pending input or ends the tool if no pending.

`-cancel`

Cancels mouse tool unconditionally.

`-cycle`

Cycles through choices for a given operation.

`-cycle_back`

Cycles back through choices for a given operation.

`-modifiers {Shift Control Alt}`

Sets the modifiers for the next mouse action. The modifiers are Shift, Control, and Alt.

`-scale double`

Sets the size of one pixel in data base units.

Description

The *gui_mouse_tool* controls the mouse tool of a view that supports mouse actions log and replay capabilities. Not all views need to support all of the functionality provided by the interface of this command. User can use the command to script varios mouse action.

Examples

The following example has the layout view start the zoom in tool and perform a zoom to particular area.

```
> gui_mouse_tool -window Layout.1 -start ZOOM_IN_TOOL
> gui_mouse_tool -window Layout.1 -add_point {27.461 433.400}
> gui_mouse_tool -window Layout.1 -add_point {51.261 393.123}
> gui_mouse_tool -window Layout.1 -cancel
```

Feedback

gui_move_lib_cell_to_family

Move lib_cells to an existing lib_cell family

Syntax

string *gui_move_lib_cell_to_family* -from *list*

-to *list* -lib_cell *lib_cell_list*

```
libcell_family list
libcell_family list
list lib_cell_list
```

Arguments

`-from list`

Family name

`-to list`

Family name

`-lib_cell lib_cell_list`

List of lib_cells

Description

The *gui_move_lib_cell_to_family* command is used to move lib_cells to another existing lib_cell family.

gui_open_error_data

Opens an error data file in the error browser.

Syntax

```
status gui_open_error_data
[-name error_data_name]
[-file_name file_name]
[error_data]
```

Data Types

```
error_data_name  string
file_name        string
error_data       list
```

Feedback

Arguments

`-name` *error_data_name*

Specifies the data name of the error data to open in the error browser. If other error data was already loaded into the error browser, the specified data is added to the existing data. This option is mutually exclusive with the *-file_name* and *error_data* options.

`-file_name` *file_name*

Specifies the name of the exported error file to open in the error browser. The name of the error data file to be opened and shown in the error browser. If other error data was already loaded into the error browser, the specified data is added to the existing data. This option is mutually exclusive with the *-name* and *error_data* options.

error_data

Specifies the data name or list of data names to open in the error browser. If the error data is already open, then a collection of the error data or the error data name can be used to show it in the error browser.

Description

The *gui_open_error_data* command displays the given error data in the GUI error browser. If the error browser is not already visible, it is first made visible.

If you specify a file name with the *-file_name* option, the command first opens an error data file with the given file name.

Note that if the command first opens an error data, it increments the open_count for an error data. Incrementing the open_count needs to be balanced by the same number of decrementing the open_count before the error data is closed and removed from memory.

The *gui_open_error_data* command opens an error data only when necessary. It does not increment the open_count if the error data is already open and in memory. If the *gui_open_error_data* command increments the open_count, then a subsequent call to *gui_close_error_data* for the same error data decrements the open_count. Otherwise, a subsequent call to *gui_close_error_data* simply removes the error_data from the error browser without decrementing the open_count.

Examples

The following example opens the physical DRC error data file that is named "my_design_dppinassgn.err" and shows it in the error browser.

```
prompt> gui_open_error_data -file_name my_design_dppinassgn.err]
```

The following example first opens the physical DRC error data file that is named "my_design_dppinassgn.err", then shows it in the error browser.

Feedback

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> gui_open_error_data $data
```

---

gui_open_utable

Open the given UserTable file.

Syntax

string *gui_open_utable*

```
-file        File_Name
[-read_only]

File_Name    String
```

Arguments

`-file` *File_Name*

The name of the file to open and copy the UserTable into memory.

`-read_only`

This flag stops the table from being copied into memory and instead the table contents are streamed which can save a lot of system memory if the table is huge.

Description

This command opens the given UserTable file and copies the table contents into memory unless the **-read_only** flag is given which causes the contents

Feedback

to be streamed in as needed. This can save system memory if the table is
 huge.

Examples

The following example opens the UserTable file 'my_table.utable' and
 copies the
table 'my_table' into memory.

```
shell> gui_open_utable -file my_table.utable
```

The following example opens the given UserTable file but instead of
 copying it
into memory it connects in read-only mode, steaming the contents as
 needed.

```
shell> gui_open_utable -file my_table.utable -read_only
```

---

gui_overlay_layout

Add/Remove/Adjust a design overlay to a layout window

Syntax

gui_overlay_layout

```
-window windowID
-design design
-add
-remove
-brightness value

windowID      String
design        String
```

Feedback

```
add           Boolean flag
remove        Boolean flag
brightness    Integer
```

Arguments

`-window windowID`

windowID specifies the layout window to add the overlay

`-design design`

design specifies the design to overlay

`-add`

add the design as an overlay

`-remove`

remove the design as an overlay

`-brightness value`

adjust the brightness of the overlay design

Description

Use this command to add, remove, or adjust an overlay on a layout view. The design to overlay must already be an opened design. You cannot overlay the same design twice nor can you overlay a design on itself. The -add and -remove flags are mutually exclusive. The brightness of an overlay can be varied from 0 (not visible at all) and 100 (fully bright). The -remove flag is mutually exclusive with the -brightness flags.

Examples

```
shell> gui_overlay_layout -window Layout.1 -design fill_view -add
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness
 Off
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness
 33%
shell> gui_overlay_layout -window Layout.1 -design fill_view -remove
```

---

gui_place_charts_plots

Place plots in charts view

Syntax

```
status gui_place_charts_plots
-view view_name
[ -vertical ]
[ -horizontal ]
```

Feedback

```
[ -rows int ]
[ -columns int ]
[ plots ]
```

Data Types

```
view_name     string
plot_id_list  list
```

Arguments

`-view view_name`

Charts View to place plots in.

`-vertical`

Stack plots vertically.

`-horizontal`

Stack plots horizontally.

`-rows int`

Stack plots in grid using the specified number of rows.

`-columns int`

Stack plots in grid using the specified number of columns.

plots

List of plots to place. If not specified then all plots are placed

Description

Place plots in a view.

Examples

The following example stacks all plots horizontally.

```
shell> gui_place_charts_plots -view $view -horizontal
```

See Also

- gui_create_charts_plot

---

gui_plot_lib_cells_attributes

Create library cells attributes plot. Returns the created window name.

Feedback

Syntax

string *gui_plot_lib_cells_attributes*

```
-families family_name_list | -lib_cells lib_cell_object_list |
 -libs lib_object_list | -libset libset_name
[-lib_cell_type  all | inv_buf | combinational | sequential | register |
 latch]
-x_attrib_name attribute_name
-y_attrib_name attribute_name
[-chart_type xy | bar | scatter]
[-analysis analysis_name_list]
[-title string]
[-pvt_index integer_list]
[-slew_index integer_list]
[-load_index integer_list]
```

Data Types

```
family_name_list  list-of-strings
lib_cell_object_list  list-of-lib_cell-objects
lib_object_list  list-of-lib-objects
libset_name  string
attribute_name  string
analysis_name_list  list-of-strings
string  string
integer_list  list-of-integers
```

Arguments

`-families` *family_name_list*

List of user-defined library cell families to plot.

`-lib_cells` *lib_cell_object_list*

A set of library cells to plot.

`-libs` *lib_object_list*

A set of libraries.

`-libset` *libset_name*

Library set name.

`-lib_cell_type all | inv_buf | combinational | sequential | register | latch`

The library cell type. Default is all. Ignored when -families is specified.

`-x_attrib_name` *attribute_name*

Library cell attribute value to use for the plot x-axis.

Feedback

`-y_attrib_name` *attribute_name*

Library cell attribute value to use for the plot y-axis.

`-chart_type xy | bar | scatter`

The plot chart type: x/y chart or bar chart or scatter chart. Default is x/y chart.

`-analysis` *analysis_name_list*

The analysis objects created by running library analysis whose data will be used to access the library cells attribute values. Default is current analysis.

`-title` *string*

The plot title.

`-pvt_index` *integer_list*

The analysis PVT pane index list. Default is 0.

`-slew_index` *integer_list*

The analysis slew index list. Default is 0.

`-load_index` *integer_list*

The analysis load index list. Default is 0.

Description

This command creates a plot window and display an x/y or bar chart plot for the library cells attribute values.

Examples

Examples of using the command:

```
define_lib_cell_family -name invs_1 -library [get_lib libA] -family_rule
 rule_INV

## avgsl_rise_delay is the averaged rise delay under the specified slew
 and load conditions
gui_plot_lib_cells_attributes -families invs_1 -x_attrib_name
 lexical_drive1_name -y_attrib_name avg_rise_delay -analysis all_cells
gui_plot_lib_cells_attributes -families invs_1 -x_attrib_name
 lexical_drive1_name -y_attrib_name avgsl_rise_delay -analysis all_cells
 -slew_index {0 1}

define_lib_cell_family -name invs_2 -library [get_lib libB] -family_rule
 rule_INV
gui_plot_lib_cells_attributes -families invs_2 -x_attrib_name
 lexical_cell_name -y_attrib_name min_fall_delay -analysis all_cells
 -load_index {0 1}
```

Feedback

```
set window [gui_plot_lib_cells_attributes -families {invs_1 invs_2}
 -x_attrib_name avg_rise_delay -y_attrib_name min_fall_delay -analysis
 all_cells]
gui_write_window_image -window $window -file lib_cells_plot.jpg

gui_plot_lib_cells_attributes -libset libset5 -lib_cell_type latch
 -x_attrib_name area -y_attrib_name max_fall_delay -analysis all_cells
```

- gui_plot_timing_arcs_attributes
- gui_write_window_image
- gui_set_charts_property

---

gui_plot_timing_arcs_attributes

Create timing arcs attributes plot. Returns the created windows names.

Syntax

list-of-strings *gui_plot_timing_arcs_attributes*

```
-timing_arcs timing_arc_object_list | -lib_cells lib_cell_object_list |
 -family family_name
-attrib_name attribute_name
[-chart_type xy | bar]
[-chart_topic lib_cell | from_to]
[-analysis analysis_name]
[-title string]
[-pvt_index integer]
[-slew_index integer]
[-load_index integer]
```

Data Types

```
timing_arc_object_list  list-of-timing_arc-objects
lib_cell_object_list  list-of-lib_cell-objects
family_name  string
attribute_name  string
analysis_name  string
string  string
integer  integer
```

Feedback

Arguments

`-timing_arcs` *timing_arc_object_list*

A set of timing arcs to plot.

`-lib_cells` *lib_cell_object_list*

A set of library cells. Plot the library cells timing arcs.

`-family` *family_name*

User-defined library cell family. Plot the family library cells timing arcs.

`-attrib_name` *attribute_name*

Timing arc attribute value to use for the plot y-axis.

`-chart_type xy | bar`

The plot chart type: x/y chart or bar chart. Default is bar chart.

`-chart_topic lib_cell | from_to`

The chart window topic: library cell or from pin -> to pin path. Default is library cell topic.

`-analysis` *analysis_name*

The analysis object created by running static analysis whose data will be used to access the library cells attribute values. Default is current analysis.

`-title` *string*

The plot title.

`-pvt_index` *integer*

The analysis PVT pane index. Default is 0.

`-slew_index` *integer*

The analysis slew index. Default is 0.

`-load_index` *integer*

The analysis load index. Default is 0.

Description

This command creates a plot window and display an x/y or bar chart plot for the timing arcs attribute values.

Feedback

Examples

Examples of using the command:

```
set a1_arcs [get_lib_timing_arcs -from [get_lib_pins */XOR4*/A1]]
set window [gui_plot_timing_arcs_attributes -timing_arcs $a1_arcs
 -attrib_name rise_delay]
gui_write_window_image -window $window -file timing_arcs_plot.jpg

set xor4_arcs [get_lib_timing_arcs -of_objects [get_lib_cells XOR4*]]
gui_plot_timing_arcs_attributes -timing_arcs $xor_arcs -attrib_name
 fall_transition

gui_plot_timing_arcs_attributes -lib_cells XOR4* -attrib_name
 fall_transition
```

---

gui_query_objects

Get the value of a query text for a collection of object.

Syntax

string *gui_query_objects*

```
        object_collection
```

Data Types

`string object_collection`

Arguments

object_collection

Specifies the collection of objects to use to get the query text.

Description

The *object_collection* command returns and displays the query text. Same text will be shown in Query toolbar for a particular object query.

Feedback

A *object_collection* is collection of objects for which the query text will be generated. The collection of objects might be returned as the result of another command such as the *get_cells* command.

For information about collections, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example displays query text for the all plan groups in the design.

```
prompt> gui_query_objects [get_plan_groups]
*********************************
Object summary:
plan_group : 5
*********************************

plan_group : RES_I109

plan_group : RES_I110

plan_group : RES_I111

plan_group : RES_I112

plan_group : RES_I113
```

The following example displays a query text for cell named RES_I112/nr02d0_B3_1.

```
prompt> gui_query_objects [get_cells RES_I112/nr02d0_B3_1]
*********************************
cell : RES_I112/nr02d0_B3_1
*********************************

---

gui_read_timing_paths

Reads a persistent path data file containing a timing path collection from some design.

Feedback

Syntax

```
string gui_read_timing_paths
-file name
[-report type]
[-blocks insts]
[-cells  clct]
[-strict_validate]
```

Data Types

```
name          string
type          Values: summary, qor
insts         list of block instances for a common block reference
clct          collection of cell objects
```

Arguments

`-file name`

Specifies the name of the persistent path data file to be read.

`-report type`

Produces various summary reports on the contents of the path data file.

Note: When this option is used, it will print the report and return. No paths are loaded.

'summary': Produces a header of the contents of the file.

'qor': Produces a summary QOR report for the file.

`-blocks insts`

Given a list of block instances, read-only paths with points that are contained in these instances. The point names and objects are adjusted to the block scope shared by these instances. This allows loading a single block design and looking at paths that are in that block design. Note: This option is mutually exclusive with the *-cells* option.

`-cells clct`

Given a collection of cells in the current design, read-only paths with points that are contained in the given cell collection. Note: This option is mutually exclusive with the *-blocks* option.

`-strict_validate`

As the paths are read in and validated against the current design, exit on any error. Otherwise only messages are produced but paths are still created.

Feedback

Description

The *gui_read_timing_paths* command reads a persistent path data file and re-creates the associated path collection. The persistent path data file written by *gui_write_timing_paths* contains all the information needed to re-create the timing paths.

Examples

The following examples read a timing path collection from a persistent path data file.

```
prompt> set mypaths [gui_read_timing_paths -file "my.paths"]
```

See Also

- gui_write_timing_paths

---

gui_read_user_map

Reads map mode data of file and display in layout, using user map mode(userMap). The command will show a dialog for user to complete the option values. If user executes the command with options, the option values will sync up to the dialog.

Syntax

string *gui_read_user_map*

```
[-file inputFile]

[-title mapTitle]

[-replace Replace current map if it exists.]

[-preview Preview data in dialogue.]
```

Data Types

```
inputFile     string
mapTitle      string
```

Arguments

`-file` *inputFile*

Specifies the name of the input file. It can be a single file name(generated in previous working directory) or have an absolute path.

For displaying the output data as a user-map, including the meta data is recommanded.

`-title` *mapTitle*

Specifies the title of the user map to display.

Feedback

`-replace`

To replace the current user map.

`-preview`

To preview data in dialogue.

Description

Read map mode data from csv file. User map is a general feature and will not have all of the features of the map that was written only the basic data presentation and bucket settings.

CSV FILE FORMAT

The input must be in format of comma-separated values (CSV) data files. The file must contain CSV data, and optionally metadata and header. The header is the top title of each column. The metadata describes the contents and structure of the CSV data. The command gui_wirte_user_map generates standard input CSV file with metadata.

The data must have at least three columns separated by comma. Optionally, it can contain a forth column indicating the data is special.

```
The first column:    region data in type of poly_rect(at least 2
 coordinates)
The second column:   data in type of integer or double
The third column:    comment in type of string
The optional column: string "Special"

The metadata must start with #META_DATA and must end with #END_META_DATA.
Here's an example with description of its attributes:

#META_DATA
#type,name,property,value      --describe column of metadata itself
#table,,tag,gui_write_user_map --tag: gui_write_user_map the file is
 generated by gui_write user_map
#table,,app_name,icc2          --file generated from icc2
#table,,version,"V1.0"         --gui_write_user_map command version
#table,,report_date,"2029-Jul-29 02:55:51" --time of creation
#table,,title,"Cell Density"   --data map title
#table,,bins,10                --data map bin number
#table,,min_threshold,0.100000 --data map min threshold value
#table,,max_threshold,1.100000 --data map max threshold value
#table,,color_scale,TemperatureScale --data map color setting
#column,Coordinates,type,poly_rect --data name and type of first column
#column,value,type,double          --data name and type of second column
#column,Comment,type,string        --data name and type of third column
#END_META_DATA

Here's an example of the input file of cell density
```

Feedback

```
map with Meta data and header:

#META_DATA
#type,name,property,value
#table,,tag,gui_write_user_map
#table,,app_name,icc2
#table,,version,"V1.0"
#table,,report_date,"2029-Jul-29 02:55:51"
#table,,title,"Cell Density"
#table,,bins,10
#table,,min_threshold,0.100000
#table,,max_threshold,1.100000
#table,,color_scale,TemperatureScale
#column,Coordinates,type,poly_rect

---

gui_remove_all_annotations

Removes specified group of annotations or all annotations from the specified layout window or from all windows.

Feedback

Syntax

```
status gui_remove_all_annotations
[-window window_name]
[-group group_name]
```

Data Types

```
window_name      string
group_name      string
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-group group_name`

Specifies the annotation group name.

Description

This command removes specified group of annotations from the specified layout window. If group name is omitted, it will remove all annotations groups. If window name is omitted, it will remove annotations from all windows. The command returns 1 if it is successful.

Examples

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \\
   -type rect -text Test1 -color green -width 2 \\
   -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_all_annotations -window Layout.1
1
```

See Also

- gui_add_annotation
- gui_remove_annotations

---

gui_remove_all_rulers

Removes rulers from the specified layout window or from all windows.

Syntax

```
status gui_remove_all_rulers
[-window window_name]
```

Feedback

Data Types

```
window_name      string
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

Description

This command removes rulers form specified layout window, or from all windows if the *-window* option is omitted, and returns 1 if it is successful.

Examples

```
prompt> gui_remove_all_rulers -window Layout.1
1
```

See Also

- gui_remove_ruler

---

gui_remove_annotations

Removes specified group of annotations from the specified layout window.

Syntax

```
status gui_remove_annotations
[-window window_name]
[-group group_name]
[anno]
```

Data Types

```
window_name      string
group_name      string
anno      collection
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-group group_name`

Specifies the annotation group name.

Feedback

`anno`

Specifies a collection of annotations to remove. Get a collection of annotations with the gui_get_annotations command. This option cannot be specified with any other option.

Description

This command removes specified group of annotations from the specified layout window. If group name is omitted, global group name is used. If window name is omitted, global window name is used. The command returns 1 if it is successful.

Examples

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \\
   -type rect -text Test1 -color green -width 2 \\
   -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_annotations -window Layout.1
1
prompt> gui_remove_annotations [gui_get_annotations -filter
 client_data==MyData]
1
```

See Also

- gui_add_annotation
- gui_remove_all_annotations
- gui_get_annotations

---

gui_remove_category_rules

Removes all category rules except built-in rules by default.

Syntax

string *gui_remove_category_rules*

`[-all | -names` *`rule_names_list`*`]`

Data Types

`rule_names_list`	`list`

Arguments

`-all`

Removes all category rules, including built-in rules.

Feedback

This option and the *-names* option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

`-names` *`rule_names_list`*

Specifies the names of the category rules to be removed.

This option and the *-all* option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

Description

This command removes category rules that have already been created by the *gui_create_category_rule* command during the current run of the tool.

When you use this command without specifying any options, it removes all category rules except built-in rules. Specify the *-all* option to remove all category rules, including the built-in rules. Specify the *-names* option to remove individual rules by name.

The command returns an empty string as its result.

Examples

The following example removes all category rules, including the built-in rules:

```
prompt> gui_remove_category_rules -all
```

The following example removes all category rules except the built-in rules:

```
prompt> gui_remove_category_rules
```

The following example removes the rules named Rule1 and Rule2:

```
prompt> gui_remove_category_rules -names {Rule1 Rule2}
```

The following example removes non-built-in rules at the top of a user-defined category rule creation script, which is being developed interactively. You can repeatedly change and refine this script by using a text editor, and you can source the script multiple times in a single run of the tool.

```
        # first remove all existing user-defined non-built-in rules
gui_remove_category_rules
# now create the user-defined category rules
gui_create_category_rule ...
gui_create_category_rule ...
and so forth
```

Feedback

See Also

- gui_create_category_rule
- gui_list_category_rules

---

gui_remove_charts_annotation

Remove annotation object from view or plot

Syntax

```
status gui_remove_charts_annotation
{ -view view_name | -plot chart_id }
{ -id string | -all }
```

Data Types

```
view_name  string
chart_id   string
```

Arguments

`-view view_name`

View to remove annotations from.

`-plot chart_id`

Plot to remove annotations from.

`-id string`

Id of annotation to remove.

`-all`

Remove all remove annotations.

Description

Removes one or all annotations from a chart or a view.

Examples

The following example removes all annotations from a view.

```
shell> gui_remove_charts_annotation -view $view -all
```

See Also

- gui_create_charts_arrow_annotation
- gui_create_charts_ellipse_annotation

Feedback

- gui_create_charts_point_annotation
- gui_create_charts_polygon_annotation
- gui_create_charts_polyline_annotation
- gui_create_charts_rectangle_annotation
- gui_create_charts_text_annotation

---

gui_remove_charts_model

Remove model from charts

Syntax

```
status gui_remove_charts_model
-model model_id
```

Data Types

```
model_id  int
```

Arguments

`-model model_id`

Charts model to remove.

Description

Remove model data from charts.

Note: It is recommended that existing plots using the model should also be removed as they may lose access to some or all of the original data.

Examples

The following example removes a model.

```
shell> gui_remove_charts_model -model $model
```

See Also

- gui_create_charts_model

---

gui_remove_charts_plot

Remove one or all plots from a charts view

Feedback

Syntax

```
status gui_remove_charts_plot
-view view_name
{ -plot chart_id | -all }
```

Data Types

```
view_name  string
chart_id   string
```

Arguments

`-view view_name`

View to remove chart from.

`-plot chart_id`

Chart to remove.

`-all`

Remove all changes.

Description

Removes one or all charts from a view.

Examples

The following example removes all charts from a view.

```
shell> gui_remove_charts_plot -view $view -all
```

---

gui_remove_image_view_file

Remove image file from image view

Syntax

```
status gui_remove_image_view_file
-window window_name
{ -image string | -all }
```

Data Types

```
window_name  string
```

Arguments

`-window window_name`

Specifies the name of the image view for which the image(s) are to be removed.

Feedback

`-image` *string*

Specifies the name of image to remove.

`-all`

Specifies that all images are to be removed.

Description

The *gui_remove_image_view_file* command allows the user to remove an existing image, or all images, from the image view.

Examples

The following example removes image named 'image1' from the current image view.

```
shell> set view [gui_get_current_window -type ImageView]
shell> gui_remove_image_view_file -window $view -image image1
```

See Also

- gui_write_window_image
- gui_get_current_window
- gui_add_image_view_file

---

gui_remove_message_waivers

Removes message waivers created in the Message Browser or by using the *gui_create_message_waiver* command.

Syntax

```
status gui_remove_message_waivers
-name waivers_name | -all
```

Data Types

```
waivers_name          string
```

Arguments

`-name` *waivers_name*

Specifies the name of the waivers to delete. This option is mutually exclusive with the *-all* option.

`-all`

Remove all waivers. This option is mutually exclusive with the *-name* option.

Feedback

Description

The *gui_remove_message_waivers* command removes message waivers created in the Message Browser or by running the *gui_create_message_waiver* command.

Examples

The following example removes waiver 'mywaiver':

```
prompt>  gui_remove_message_waivers -name mywaiver
```

See Also

- gui_create_message_waiver

---

gui_remove_pref_key

Remove a preference key.

Syntax

string *gui_remove_pref_key* -key *Key*

```
[-category Category]

Key             String
Category        String
```

Arguments

`-key Key`

Key specifies the key which will be used together with the specified category to uniquely identify the key to be removed.

`-category Category`

Category specifies the category that owns the specified key. If not specified, a default category will be used.

Description

This command removes the preference key specified by the key name.

- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_remove_ruler

Removes the specified rulers.

Syntax

```
status gui_remove_ruler
[-window window_name]
-point point | -all
```

Data Types

```
window_name      string
point            point
```

Arguments

`-window window_name`

Specifies the instance name of the layout window.

`-point point`

Specifies the coordinates of the point near the ruler to be removed, in following format:

```
{x y}
```

`-all`

Removes all rulers.

Description

This command removes rulers from the specified layout window, or from all windows if the *-window* option is omitted, and returns 1 if it is successful.

Feedback

Examples

```
prompt> gui_remove_ruler -window Layout.1 -point {400 400}
1
prompt> gui_remove_ruler -window Layout.1 -all
1
```

See Also

- gui_remove_all_rulers

---

gui_remove_user_map

Remove current/all user map mode.

Syntax

string *gui_write_user_map*

```
[-all]
```

Arguments

`-all`

Remove all user map mode.

Description

Remove current/all user map mode.

Examples

```
Remove current user map in layout:

prompt>gui_remove_user_map
```

See Also

- gui_read_user_map
- gui_write_user_map

---

gui_remove_vm

Remove Visual Mode

Syntax

string *gui_remove_vm* -name *identifier*

Feedback

```
string identfier
```

Arguments

```
-name identifier
```

Specifies the name of the visual mode to be removed.

Description

Removes the specified visual mode and all the associated buckets.

Examples

To remove visual mode named "mycoloring1", use the following command:

shell> *gui_remove_vm -name mycoloring1*

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_get_vm
- gui_get_vmbucket
- gui_list_vm
- gui_remove_vmbucket
- gui_set_vmbucket
- gui_update_vm

---

gui_remove_vmbucket

Removes the specified bucket or all buckets from the specified visual mode

Syntax

string *gui_remove_vmbucket*

-vmname *mode_identifier* [-name *bucket_identifier*] [-all]

Data Types

```
mode_identifier     string
bucket_identifier   string
```

Feedback

Arguments

`-vmname` *mode_identifier*

Specifies the visual mode of which the bucket is a member. The visual mode must already exist.

`-name` *bucket_identifier*

Specifies the name of the bucket to be removed from the specified visual mode.

`-all`

Removes all buckets associated with the specified visual mode.

Description

Removes the specified bucket or all buckets from the specified visual mode.

Examples

To remove the visual mode bucket named red from the visual mode named vm1, enter the following command:

```
prompt> gui_remove_vmbucket -vmname vm1 -name red
```

To remove all the visual mode buckets from the visual mode named vm1, enter the following command:

```
prompt> gui_remove_vmbucket -vmname vm1 -all
```

---

gui_report_errors

Output a textual report of errors.

Feedback

Syntax

string *gui_report_errors*

[-errors *Errors*] [-file *FileName*] [-include_hidden]

```
Errors          String
FileName        String
```

Arguments

`-errors Errors`

The *-errors* specifies the handle for a collection of errors to report on. This argument is optional. If omitted, a report is output for the errors currently loaded in the Error Browser error list.

`[-file FileName]`

FileName specifies the name of the file to write the report to. This argument is optional. If omitted, the report is output to stdout.

`[-include_hidden]`

-include_hidden specifies that errors that are currently hidden from the errors list due to filters or fixed errors being hidden should be included in the report. This option is ignored if errors are given with the *-errors* option.

Description

This command outputs a tabular textual representation of errors. If the -errors argument is omitted and an output file is specified, performs the same operation as the Error Browser option menu command to save to file.

Examples

The following example saves a textual report of current errors to a file named myErrors.txt:

gui_report_errors -file "myErrors.txt"

See Also

- gui_error_browser
- gui_set_current_errors

---

gui_report_hotkeys

Report on the current hotkey bindings

Feedback

Syntax

string *gui_report_hotkeys*

```
[-window_type WindowTypeName]

WindowTypeName  String
```

Arguments

`-window_type` *WindowTypeName*

WindowTypeName specifies the type of top level window that the hotkey should apply to. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable gui_default_window_type(3) specifies the default window type for the application.

Description

This command prints a report on the current key bindings. The list of bindings printed in the report are sorted by hotkey.

Examples

The following example creates a menu item and add an additional hotkey to it.

```
gui> gui_report_hotkeys

****************************************
Report : hotkeys
Window : LayoutWindow
Version: V-2004.06-GALILEO-BETA1-1
Date   : Tue Aug 31 10:37:17 2004
****************************************

Hot Key    Type  Function
-------------------------------------------------------
Ctrl+O     Menu  File->Open Design...
Ctrl+S     Menu  File->Save Design
Ctrl+R     Menu  Edit->Properties
M          Menu  Edit->Move...
C          Menu  Edit->Copy...
Ctrl+F     Menu  View->Zoom->Zoom Full
F          Menu  View->Zoom->Zoom Full
P          Tcl   query_objects [get_selection]
 ...
```

gui_report_map

Report information for a specified map mode.

Syntax

string *gui_report_map*

```
-name identifier
-report_type outputType
```

Data Types

identifier	string
outputType	string (Values: histogram, count)

Arguments

`-name` *identifier*

Specifies the name of the map mode to be queried.

`-report_type outputType`

Specifies the mode of report. Value of *outputType* can be *histogram* or *count*.

Description

The *gui_report_map* command queries the option values of an existing map mode name and a report mode. Histogram mode will print '###' as a graph bar for each bucket. Count mode will generate only count numbers of blocks in each bucket.

Feedback

Examples

To generate a histogram data for the map mode named "cellDensityMap". Use the following command:

```
prompt>gui_report_map -name cellDensityMap -report_type histogram
**************************************
Report : map
Design : ORCA
Mode   : histogram
Version: P-2019.03-DEV
Date   : Tue Nov  6 22:01:35 2018

---

gui_report_performance

Generates a performance report.

Syntax

```
status gui_report_performance
[-type report_type]
[-file file_name]
[-compress compress_method]
```

Data Types

```
report_type       string
file_name          string
compress_method   string
```

Feedback

Arguments

`-type` *report_type*

Specifies the report type. If report type is omitted or the value of this option is simple, output a simple version report. If the value of this option is detail, output a detail version report which includes additional information of x11 performance, region searching, attribute querying and render time.

The supported values for this option are

simple
detail

`-file` *file_name*

Outputs the report as a file and specifies the file name. If file name is omitted, output the report to console.

`-compress` *compress_method*

Specifies the compress method. The supported values for this option are

none
gzip

Description

This command report the performance data of machine state, design information, GUI configurations and current GUI views state.

Examples

```
Generate a simple version report and output to console.

prompt> gui_report_performance

Generate a detail version report and output to a file.

prompt> gui_report_performance -type detail -file file_name

Generate a detail version report and output to a compressed file

prompt> gui_report_performance -type detail -file file_name -compress
 gzip
```

---

gui_report_proc_arg_type_names

Report on the available type_name attribute values.

Feedback

Syntax

string *gui_report_proc_arg_type_names*

Description

This command prints a report on the available values for the type_name attribute for the *-define_args* argument to the *define_proc_attributes* command.

When a tcl proc has been defined using the *define_proc_attribute* command, a GUI form for the command will be auto-generated and shown from the application command search feature or using the command *gui_show_command_form*. The kinds of proc argument input fields used in the generated GUI form depend on the *type_name* attribute values provided for command options. The *type_name* attribute value for an option is given as a part of the *-define_args* argument. The *-define_args* option accepts a list of the following values, in this order:

```
* option name
* option decription
* option value type description
* data_type
* list of option attribute name-value pairs
```

Here is the usage for the *type_name* attribute within argument value for the *define_proc_attributes* command option *-define_args*:

```
define_proc_attributes <procedure name> \\
  -define_args { \\
    {<option name> <option description> <value type description>
 <data_type> \\
      {[required | optional] {type_name <type_name_value>}} \\
  } \\
}
```

where <type_name_value> can be substituted with any of the type names reported by *gui_report_proc_arg_type_names*.

For the *type_name* attribute value to have effect on the input field used in a GUI form, the <data_type> value must be *string*, for a single value, or *list* for multiple values. The value *list* is not supported for all *type_name* values as shown in the report's *data_type* column.

The following is an example of a *define_proc_attribute* command invocation with options accepting a collection or names of nets:

```
define_proc_attributes myProc \\
  -define_args { \\
    {-net "select a net" "net name or a collection of a net" string \\
          {optional {type_name net}}} \\
    {-nets "select nets" "net names or a collection of nets" list   \\
          {optional {type_name net}} \\
```

Feedback

```
  } \\
}
```

In the above example, the *-net* option has *data_type* value *string* and *type_name* value *net*. This option accepts a single net as input. The *-nets* option has *data_type* value *list* and *type_name* value *net*. This option accepts multiple nets as input.

The report produced by this command lists the available *type_name* values. When one of these supported *type_name* values is used, the GUI form for the proc will use an input field that is appropriate for user input of that kind of value. For example, for a *net* type input, as shown in the example above, the form will use an object selector field which is configured to accept net input.

A proc argument with any combination of unspecified or unsupported *data_type* and *type_name* values is represented with a simple text input field in the generated GUI form.

Some *type_name* values use input editors that allow further configuration. For example, an editor for a file name can be configured to allow input of only existing files. Or an editor for a layer name can be configured to allow input of only certain types of layers.

Available configuration options are shown in the options column, then described in more detail at the end of the report output in a separate table keyed by associate type_name values. When providing optional configuration, list the configuration name-value pairs after the type_name value as a part of the the type_name attribute value. The following is an example of a "file" type_name attribute with multiple optional configuration settings:

```
define_proc_attributes myProc \\
  -define_args { \\
    {-file_option "Select an existing file name" "file name"  string \\
      {required
        {type_name {file {subtype exist} \\
                         {operation "Save As"} \\
                         {filter {"Text files (*.txt)" "All files (*)"}}
 \\
                   } \\
        } \\
      } \\
    } \\
  }
```

Examples

The following example outputs a report of available type_name attribute values.

```
gui> gui_report_proc_arg_type_names
****************************************************************************
*****
Report : Supported Values for "type_name" Option Attribute
Version: L-2016.03-SP5-BETA
Date   : Fri Sep 16 08:09:34 2016
```

Feedback

```

Feedback

gui_report_task

task.

Syntax

string *gui_report_task*

```
-task | -item_root          TaskName | ItemRootName
[-file]                     FileName

TaskName          String
ItemRootName      String
FileName          String
```

Arguments

`-task` *TaskName*

TaskName specifies the name of a task on which to report. This option is mutually exclusive with the -item_root option.

`-item_root` *ItemRootName*

ItemRootName specifies the name of a task item root name on which to report. This option is mutually exclusive with the -task option.

`-file` *FileName*

FileName optionally specfies the output file into which the report is written.

Description

This command outputs a textual report of the given task to the xterm console. If -file is given, then the report is also output to the given file. The report will have the following approximate format. The strings bracketed with the angle brackets will be replaced with the actual attribute value.

Attributes are omitted if they are not defined. Item are shown one to a line with the hierarchy structure indicated by indentations and bars. The leaf-leveltask item names are followed by the associated task page name:

```
Task: <task name>
 Default: <true | false>
 Items: <items>
```

See Also

Feedback

gui_schematic_add_logic

Adds logic to a schematic

Syntax

string *gui_schematic_add_logic* [-window <*win*>]

[-new] [-schematic <*schem*>] *objs*

```
string <win>
string <schem>
string objs
```

Arguments

`-window <win>`

Top level window name to place new schematic (default: current window). This option is ignored unless -new is specified.

`-new`

Create new schematic.

`-schematic <schem>`

Schematic view to update (default: most recently active schematic).

objs

Objects to add to the schematic.

Description

This command adds logic into a Path Schematic view. The command either creates a new view containing the specified objects or updates an existing view. The command always returns the name of the schematic that was updated or created.

Examples

The following example creates a new path schematic containing all the cells in the current design:

```
gui_schematic_add_logic -new [get_cells *]
```

See Also

- gui_get_current_window
- gui_schematic_remove_logic

Feedback

gui_schematic_remove_logic

Removes logic from a schematic

Syntax

string *gui_schematic_remove_logic* [-schematic <*schem*>] *objs*

```
string <schem>
string objs
```

Arguments

`-schematic <schem>`

Schematic view to update (default: most recently active schematic).

objs

Objects to remove from the schematic.

Description

This command removes logic into a Path Schematic view. The command returns the name of the schematic that was updated

Examples

The following example removes the cell "U1" from the most recently active schematic view:

```
gui_schematic_remove_logic [get_cells U1]
```

See Also

- gui_get_current_window
- gui_schematic_add_logic

gui_scroll

Scroll a window's viewport.

Syntax

gui_scroll

-window *window* [-selection | -clct *clct* | [-habs *absX* | -hrel *relX*] [-vabs *absY* | -vrel *relY*]]

```
window String
absX  Float
relX  Float
```

Feedback

```
absY  Float
relY  Float
```

Arguments

`-window` *window*

window specifies the window to be scrolled.

`-selection`

Determine the bounding box for all selected objects present in the view, and scroll such that the center of that box is visible.

`-clct` *clct*

Determine the bounding box for the collection objects present in the view, and scroll such that the center of that box is visible.

`-habs` *absX*

Scroll such that the specified X model position is centered in the viewport.

`-hrel` *relX*

Scroll horizontally by the specified number of pages. A page is the width of the viewport. Negative values scroll left and positive values scroll right.

`-vabs` *absY*

Scroll such that the specified Y model position is centered in the viewport.

`-vrel` *relY*

Scroll vertically by the specified number of pages. A page is the height of the viewport. Negative values scroll up and positive values scroll down.

Description

The *gui_scroll* command adjusts the position of views that support zooming. The viewport can be adjusted in the X and/or Y direction. Absolute values are expressed in model coordinates. Relative values allow paging. For example, *-hrel 1.0* means page to the right by the width of the viewport.

Examples

Scroll such that model coordinates (287.0, 1422.0) are centered in the viewport.

```
gui_scroll -window Layout.1 -habs 287.0 -vabs 1422.0
```

Scroll to the right by one viewport width.

```
gui_scroll -window Layout.1 -hrel 1.0
```

gui_select_bundles_of_selected

Select the bundles of the selected objects.

Syntax

```
status gui_select_bundles_of_selected
```

Description

The *gui_select_bundles_of_selected* command selects the bundles related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the bundles associated with the nets of the selected net, routing_corridor, routing_corridor_shape, pin, port, terminal, shape, and via objects.

Examples

Select the bundles of the selected objects.

```
prompt> gui_select_bundles_of_selected
```

See Also

- change_selection
- get_bundles

---

gui_select_by_name

Select or highlight objects by name

Syntax

```
status gui_select_by_name
[ { -select | -highlight } ]
-object_type string
[ -pattern string ]
[ -filter string ]
[ { -replace | -add | -remove } ]
[ -regexp ]
[ -nocase ]
[ -exact ]
[ -all ]
```

Feedback

Arguments

`-select`

Specifies that the matching objects are to be selected.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

`-highlight`

Specifies that the matching objects are to be highlighted.

Note: only one of *-select* or *-highlight* options should be specified. If neither is specified, *-select* is assumed.

`-object_type` *`string`*

Specifies the type of objects to be selected.

The available types are dependant on the individual product. To list the currently supported types use the string "?" for the object type.

`-pattern` *`string`*

Specifies the pattern to be used for a match.

By default matching is case-sensitive and uses wildcard patterns. If non case-sensitive matching is required use the *-nocase* option. If regular expression matching is required use the *-regexp* option. If no pattern matching is required use the *-exact* option.

`-filter` *`string`*

Specifies the expression to use when filtering the results.

`-replace`

Specifies that matching objects should replace the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

`-add`

Specifies that matching objects should be added to the current selection or highlight.

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

`-remove`

Specifies that matching objects should be removed from the current selection or highlight.

Feedback

Note: only one of the *-replace*, *-add* or *-remove* options can be specified. If none of these options area specified, then replace is assumed.

`-regexp`

Specifies the pattern matching should use regular expressions.

`-nocase`

Specifies the pattern matching should be case-insensitive.

`-exact`

Specifies that no pattern matching should be used so wildcards and regular expressions are ignored.

`-all`

Specifies that physical only objects be include in the search.

Description

This command allows objects of a specified type to be selected or highlighted.

It is used by the Select By Name Toolbar and Select By Name Dialog for correct log and replay of the resultant selection or highlight.

The command returns whether the search was successful or not.

Examples

The following example will add all nets matching the pattern 'A*' to the current selection.

```
shell> gui_select_by_name -select -object_type {Nets} -pattern {A*} -add
```

The following example will only highlight the Port '*Logic0*'.

```
shell> gui_select_by_name -highlight -object_type {Ports} -pattern
 {*Logic0*} -exact
```

The following example lists all object types

```
shell> gui_select_by_name -object_type ?
```

gui_select_cell_buses_of_selected

Select the cell buses of the selected objects.

Feedback

Syntax

```
status gui_select_cell_buses_of_selected
```

Description

The *gui_select_cell_buses_of_selected* command selects the cell buses related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the expanded cell buses associated with the selected cell.

Examples

Select the cell buses of the selected objects.

```
prompt> gui_select_cell_buses_of_selected
```

See Also

- change_selection
- get_cell_buses

---

gui_select_cells_of_selected

Select the cells of the selected objects.

Syntax

```
status gui_select_cells_of_selected
```

Description

The *gui_select_cells_of_selected* command selects the cells related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Cells that are already selected remain selected, while net, pin, shape, and via objects will have their related cells selected.

Examples

Select the cells of the selected objects.

```
prompt> gui_select_cells_of_selected
```

See Also

- change_selection
- get_cells

Feedback

gui_select_connected_net_shapes

Selects the net shapes physically connected to the selected net shapes on the same nets.

Syntax

status *gui_select_connected_net_shapes*

```
[-hierarchical]
[-cross_net]
```

Arguments

`-hierarchical`

Traces connections across hierarchical module boundaries. For example, all net shapes of a connected feedthrough net are selected in one operation when this option is specified.

`-cross_net`

Traces physically connected shapes across different nets, except PG nets.

Description

The *gui_select_connected_net_shapes* command selects the physically connected net shapes of the currently selected net shapes. It is intended for interactive usage in the GUI for the application.

Examples

Select the objects of the selected net shapes.

```
prompt> gui_select_connected_net_shapes
```

See Also

- change_selection
- get_shapes

gui_select_connected_rdl_net_shapes

Selects the RDL net shapes physically connected to the selected RDL net shapes.

Syntax

```
status gui_select_connected_rdl_net_shapes
```

Arguments

This command has no arguments.

Feedback

Description

The *gui_select_connected_rdl_net_shapes* command selects the physically connected RDL net shapes of the currently selected net shapes. It is intended for interactive usage in the GUI for the application.

RDL net shapes can have multiple paths from a driver to a bump. This command only selects the RDL net shapes on the same path as the currently selected net shapes.

Examples

Select the objects of the selected RDL net shapes.

```
prompt> gui_select_connected_rdl_net_shapes
```

See Also

- change_selection
- get_shapes

---

gui_select_connected_topology_of_selected

Adds the topology objects (edges, repeaters, and nodes) connected to the selected topology objects to the current selection.

Syntax

```
status gui_select_connected_topology_of_selected
```

Description

The *gui_select_connected_topology_of_selected* command adds to selection the topology objects (edges, repeaters, and nodes) connected to the currently selected topology objects. The connected topology objects are defined as follows: group of nodes, edges, and repeaters joined together by edges. It is intended for interactive usage in the GUI for the application.

Examples

Adds the topology nodes, edges, and repeaters connected to the selected objects to the current selection.

```
prompt> gui_select_connected_topology_of_selected
```

See Also

- gui_select_topology_nodes_of_selected

- get_topology_nodes
- get_topology_edges
- get_topology_repeaters
- get_topology_plans

gui_select_connections_of_selected

Select the connections of the selected objects.

Syntax

```
status gui_select_connections_of_selected
```

Description

The *gui_select_connections_of_selected* command selects the connections related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Ports and Pins that are already selected remain selected, while cell, net, shape, via, terminal, bound, pin_guide, pin_blockage, and design objects will have their related connections selected.

Examples

Select the connections of the selected objects.

```
prompt> gui_select_connections_of_selected
```

See Also

- gui_select_output_connections_of_selected
- gui_select_input_connections_of_selected
- change_selection
- get_ports
- get_pins

gui_select_constraint_groups_of_selected

Select the constraint groups of the selected objects.

Feedback

Syntax

```
status gui_select_constraint_groups_of_selected
```

Description

The *gui_select_constraint_groups_of_selected* command selects the constraint groups related to the currently selected nets, topology nodes, or topology edges. It is intended for interactive usage in the GUI for the application. Net, topology node, and topology edge objects will have their related constraint groups selected.

Examples

Select the constraint groups of the selected objects.

```
prompt> gui_select_constraint_groups_of_selected
```

---

gui_select_dependent_objects_of_selected

Select the dependent objects that are associated with the selected objects.

Syntax

```
status gui_select_dependent_objects_of_selected
```

Description

The *gui_select_dependent_objects_of_selected* command selects the dependent objects of the selected anchors and anchor objects. It is intended for interactive usage in the GUI for the application.

Examples

Select the dependent objects that are associated with the selected objects.

```
prompt> gui_select_dependent_objects_of_selected
```

Feedback

See Also

- change_selection
- create_anchor
- get_anchors

---

gui_select_failsafe_fsm_groups_of_selected

Selects the failsafe FSM groups of the selected objects.

Syntax

```
status gui_select_failsafe_fsm_groups_of_selected
```

Description

The *gui_select_failsafe_fsm_groups_of_selected* command selects the failsafe FSM groups related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Failsafe FSM groups that are already selected remain selected, while when a pin or failsafe FSM rule object is selected, this command returns their related failsafe FSM groups.

Examples

Select the failsafe FSM groups of the selected objects.

```
prompt> gui_select_failsafe_fsm_groups_of_selected
```

See Also

- change_selection
- get_failsafe_fsm_groups

---

gui_select_failsafe_fsm_rules_of_selected

Selects the failsafe FSM rules of the selected objects.

Syntax

```
status gui_select_failsafe_fsm_rules_of_selected
```

Description

The *gui_select_failsafe_fsm_rules_of_selected* command selects the failsafe FSM rules related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Failsafe FSM rules that are already selected remain selected, while when

Feedback

a pin or failsafe FSM group object is selected, this command returns their related failsafe FSM rules.

Examples

Select the failsafe FSM rules of the selected objects.

```
prompt> gui_select_failsafe_fsm_rules_of_selected
```

See Also

- change_selection
- get_failsafe_fsm_rules

---

gui_select_flops_of_selected

Selects the flops of the selected objects.

Syntax

```
status gui_select_flops_of_selected
```

Description

The *gui_select_flops_of_selected* command selects the flops related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Flops that are already selected remain selected, while for cell, safety register rule, and safety register group objects, this command returns their related flops.

Examples

Select the flops of the selected objects.

```
prompt> gui_select_flops_of_selected
```

See Also

- change_selection

---

gui_select_input_connections_of_selected

Select the input connections of the selected objects.

Syntax

```
status gui_select_input_connections_of_selected
```

Feedback

Description

The *gui_select_input_connections_of_selected* command selects the input connections related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Ports and Pins that are already selected remain selected, while cell, net, shape, via, terminal, bound, pin_guide, pin_blockage, and design objects will have their related input connections selected.

Examples

Select the input connections of the selected objects.

```
prompt> gui_select_input_connections_of_selected
```

See Also

- gui_select_output_connections_of_selected
- gui_select_connections_of_selected

---

gui_select_keepout_margins_of_selected

Select the keepout margins of the selected objects.

Syntax

```
status gui_select_keepout_margins_of_selected
```

Description

The *gui_select_keepout_margins_of_selected* command selects the keepout margins related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Keepout margins that are already selected remain selected, while cell objects will have their related keepout margins selected.

Examples

Select the keepout margins of the selected objects.

```
prompt> gui_select_keepout_margins_of_selected
```

Feedback

See Also

- change_selection
- get_keepout_margins

---

gui_select_macros_of_selected

Select the macros of the selected objects.

Syntax

```
status gui_select_macros_of_selected
```

Description

The *gui_select_macros_of_selected* command selects the macros within the currently selected objects. It is intended for interactive usage in the GUI for the application. Macros that are already selected remain selected, while the macros within selected design or hierarchy boundaries are also selected.

Examples

Select the macros of the selected objects.

```
prompt> gui_select_macros_of_selected
```

See Also

- change_selection
- get_cells

---

gui_select_manufacturing_shapes_of_selected

Select the manufacturing shapes of the selected objects.

Syntax

```
status gui_select_manufacturing_shapes_of_selected
```

Description

The *gui_select_manufacturing_shapes_of_selected* command selects the manufacturing shapes related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Manufacturing shapes that are already selected remain selected, while design, cell, objects will have their related bounds selected.

Feedback

Examples

Select the manufacturing shapes of the selected objects.

```
prompt> gui_select_manufacturing_shapes_of_selected
```

See Also

- change_selection
- get_manufacturing_shapes

---

gui_select_matching_types_of_selected

Select the matching types of the selected cells, pins, or terminals.

Syntax

```
status gui_select_matching_types_of_selected
```

Description

The *gui_select_matching_types_of_selected* command selects the matching types related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Matching types that are already selected remain selected, while pins, terminals and cells will have their related matching types selected.

Examples

Select the matching types of the selected objects.

```
prompt> gui_select_matching_types_of_selected
```

See Also

- change_selection
- get_matching_types

---

gui_select_materials_of_selected

Selects the materials of the selected objects

Syntax

string *gui_select_materials_of_selected*

Arguments

This command has no arguments.

Feedback

Description

The *gui_select_materials_of_selected* command selects the materials related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Materials that are already selected remain selected, while when a process layer object is selected, this command returns their related materials.

Examples

Select the materials of the selected objects.

```
prompt> gui_select_materials_of_selected
```

See Also

- gui_select_process_layers_of_selected

---

gui_select_metal_area_holes_of_selected

Selects the metal area holes of the selected objects

Syntax

string *gui_select_metal_area_holes_of_selected*

Arguments

This command has no arguments.

Description

The *gui_select_metal_area_holes_of_selected* command selects the metal area holes related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Metal area holes that are already selected remain selected, while when a metal area object is selected, this command returns their related metal area holes.

Examples

Select the metal area holes of the selected objects.

```
prompt> gui_select_metal_area_holes_of_selected
```

See Also

- gui_select_metal_areas_of_selected

---

gui_select_metal_areas_of_selected

Selects the metal areas of the selected objects

Feedback

Syntax

string *gui_select_metal_areas_of_selected*

Arguments

This command has no arguments.

Description

The *gui_select_metal_areas_of_selected* command selects the metal areas related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Metal areas that are already selected remain selected, while when a metal area hole object or net object is selected, this command returns their related metal areas.

Examples

Select the metal areas of the selected objects.

```
prompt> gui_select_metal_areas_of_selected
```

See Also

- gui_select_metal_area_holes_of_selected

---

gui_select_mib_cells_of_selected

Selects the associated MIB cells of the selected macro cells.

Syntax

```
status gui_select_mib_cells_of_selected
```

Description

The *gui_select_mib_cells_of_selected* command selects the associated multiply instantiated block (MIB) cells of the currently selected macro cells.

It is intended for interactive usage in the GUI for the application.

If the command fails then the selection is not changed.

Examples

Select the MIB cells of the selected macro cells.

```
prompt> gui_select_mib_cells_of_selected
```

Feedback

See Also

- change_selection
- gui_select_mib_connections_of_selected

---

gui_select_mib_connections_of_selected

Selects the associated MIB connections of the selected macro connections.

Syntax

```
status gui_select_mib_connections_of_selected
```

Description

The *gui_select_mib_connections_of_selected* command selects the associated multiply instantiated block (MIB) connections (pins) of the currently selected macro connections (macro pins).

It is intended for interactive usage in the GUI for the application.

If the command fails then the selection is not changed.

Examples

Select the MIB connections of the selected macro connections.

```
prompt> gui_select_mib_connections_of_selected
```

See Also

- change_selection
- gui_select_mib_cells_of_selected

---

gui_select_mib_topology_instances_of_selected

Selects the associated MIB topology edges is a topology edge is selected or associated MIB topology plan if a topology plan is selected.

Syntax

```
status gui_select_mib_topology_instances_of_selected
```

Description

The *gui_select_mib_topology_instances_of_selected* command selects the associated MIB topology edges is a topology edge is selected or associated MIB topology plan if a topology plan is selected.

Feedback

It is intended for interactive usage in the GUI for the application.

If the command fails then the selection is not changed.

Examples

Select the MIB topology edges of the selected topology edge.

```
prompt> change_selection [get_topology_edges TOPOLOGY_EDGE0]
prompt> gui_select_mib_cells_of_selected
```

See Also

- change_selection

---

gui_select_modules_of_selected

Select the modules of the selected objects.

Syntax

```
status gui_select_modules_of_selected
```

Description

The *gui_select_modules_of_selected* command selects the modules related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Modules that are already selected remain selected, while cell objects will have their related modules selected.

Examples

Select the modules of the selected objects.

```
prompt> gui_select_modules_of_selected
```

See Also

- change_selection
- get_modules
- get_cells

---

gui_select_net_buses_of_selected

Select the net buses of the selected objects.

Feedback

Syntax

```
status gui_select_net_buses_of_selected
```

Description

The *gui_select_net_buses_of_selected* command selects the net buses related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the net buses associated with the selected net.

Examples

Select the net buses of the selected objects.

```
prompt> gui_select_net_buses_of_selected
```

See Also

- change_selection
- get_net_buses

---

gui_select_net_routing_of_selected

Select the shapes and vias of the nets related to the selected objects.

Syntax

```
status gui_select_net_routing_of_selected
```

Description

The *gui_select_net_routing_of_selected* command selects the routing for the nets of the currently selected objects. It is intended for interactive usage in the GUI for the application. Shapes and Vias that are already selected remain selected, while cell, pin, net, terminal, and port objects will have the routing for their nets selected.

Examples

Select the routing of the selected objects.

```
prompt> gui_select_net_routing_of_selected
```

See Also

- change_selection
- get_shapes
- get_vias

Feedback

gui_select_net_shapes_of_selected

Select the shapes of the nets of the selected objects.

Syntax

```
status gui_select_net_shapes_of_selected
```

Description

The *gui_select_net_shapes_of_selected* command selects the shapes of the nets of the currently selected objects. It is intended for interactive usage in the GUI for the application. Shapes that are already selected remain selected, while cell, pin, net, terminal, and port objects will have the shapes of their nets selected.

Examples

Select the shapes of the nets of the selected objects.

```
prompt> gui_select_net_shapes_of_selected
```

See Also

- change_selection
- get_shapes

gui_select_net_vias_of_selected

Select the vias of the nets of the selected objects.

Syntax

```
status gui_select_net_vias_of_selected
```

Description

The *gui_select_net_vias_of_selected* command selects the vias of the nets of the currently selected objects. It is intended for interactive usage in the GUI for the application. Vias that are already selected remain selected, while cell, pin, net, terminal, and port objects will have the vias of their nets selected.

Examples

Select the vias of the nets of the selected objects.

```
prompt> gui_select_net_vias_of_selected
```

Feedback

See Also

- change_selection
- get_vias

---

gui_select_nets_of_selected

Select the nets of the selected objects.

Syntax

```
status gui_select_nets_of_selected
[-hierarchical]
```

Arguments

`-hierarchical`

If this option is specified then all hierarchical nets of the original logical net are selected.

Description

The *gui_select_nets_of_selected* command selects the nets related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Nets that are already selected remain selected, while cell, pin, shape, via, terminal, port, and bundle objects will have their related nets selected.

Examples

Select the nets of the selected objects.

```
prompt> gui_select_nets_of_selected
```

See Also

- change_selection
- get_nets

---

gui_select_objects_of_selected_edit_group

Select the objects of the selected edit groups.

Syntax

```
status gui_select_objects_of_selected_edit_group
```

Feedback

Description

The *gui_select_objects_of_selected_edit_group* command selects the objects of the currently selected edit groups. It is intended for interactive usage in the GUI for the application.

Examples

Select the objects of the selected edit group.

```
prompt> gui_select_objects_of_selected_edit_group
```

See Also

- change_selection
- get_edit_groups

---

gui_select_output_connections_of_selected

Select the output connections of the selected objects.

Syntax

```
status gui_select_output_connections_of_selected
```

Description

The *gui_select_output_connections_of_selected* command selects the output connections related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Ports and Pins that are already selected remain selected, while cell, net, shape, via, terminal, bound, pin_guide, pin_blockage, and design objects will have their related output connections selected.

Examples

Select the output connections of the selected objects.

```
prompt> gui_select_output_connections_of_selected
```

See Also

- gui_select_input_connections_of_selected

- get_pins

Feedback

gui_select_pin_buses_of_selected

Select the pin buses of the selected objects.

Syntax

```
status gui_select_pin_buses_of_selected
```

Description

The *gui_select_pin_buses_of_selected* command selects the pin buses related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the expanded pin buses associated with the selected pin.

Examples

Select the pin buses of the selected objects.

```
prompt> gui_select_pin_buses_of_selected
```

See Also

- change_selection
- get_pin_buses

gui_select_pin_constraints_of_selected

Select the pin_constraints of the selected objects.

Syntax

```
status gui_select_pin_constraints_of_selected
```

Description

The *gui_select_pin_constraints_of_selected* command selects the pin constraints related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the pin constraints associated with the net, bundle, pin, port objects.

Examples

Select the pin constraints of the selected objects.

```
prompt> gui_select_pin_constraints_of_selected
```

Feedback

See Also

- change_selection
- get_pin_constraints

---

gui_select_placement_attraction_of_selected

Select the placement attraction of the selected objects.

Syntax

```
status gui_select_placement_attraction_of_selected
```

Description

The *gui_select_placement_attraction_of_selected* command selects the placement attraction related to the currently selected objects. It is intended for interactive usage in the GUI for the application.

Examples

Select the placement attraction of the selected objects.

```
prompt> gui_select_placement_attraction_of_selected
```

See Also

- change_selection
- get_placement_attractions

---

gui_select_port_buses_of_selected

Select the port buses of the selected objects.

Syntax

```
status gui_select_port_buses_of_selected
```

Description

The *gui_select_port_buses_of_selected* command selects the port buses related to the currently selected objects. It is intended for interactive usage in the GUI for the application. This command will select the port buses associated with the selected port.

Examples

Select the port buses of the selected objects.

Feedback

```
prompt> gui_select_port_buses_of_selected
```

See Also

- change_selection
- get_port_buses

---

gui_select_ports_of_selected_power_supply_nets

Selects the ports of the selected power supply nets.

Syntax

```
status gui_select_ports_of_selected_power_supply_nets
```

Description

The *gui_select_ports_of_selected_power_supply_nets* command selects the ports and pins of blocks hierarchically related to the currently selected supply nets. The relationship is determined by *get_related_supply_nets* command. It is intended for interactive usage in the GUI for the application.

Examples

Select the ports, and pins of blocks selected supply nets.

```
prompt> gui_select_ports_of_selected_power_supply_nets
```

See Also

- change_selection
- get_ports

---

gui_select_primary_power_supply_nets_of_selected

Select the primary power supply nets of the selected voltage areas, voltage area shapes, power domains.

Syntax

```
status gui_select_primary_power_supply_nets_of_selected
```

Description

The *gui_select_primary_power_supply_nets_of_selected* command selects the supply nets related to the currently selected voltage areas and power domains as primary power supply. It is intended for interactive usage in the GUI for the application. Voltage_areas, voltage area shapes, and power domains already selected will have their related primary power supply net selected.

Examples

Select the primary power supply nets of the selected objects.

```
prompt> gui_select_primary_power_supply_nets_of_selected
```

Feedback

gui_select_process_layers_of_selected

Selects the process_layers of the selected objects

Syntax

string *gui_select_process_layers_of_selected*

Arguments

This command has no arguments.

Description

The *gui_select_process_layers_of_selected* command selects the process_layers related to the currently selected objects. It is intended for interactive usage in the GUI for the application. process_layers that are already selected remain selected, while when a material object is selected, this command returns their related process_layers.

Examples

Select the process_layers of the selected objects.

```
prompt> gui_select_process_layers_of_selected
```

See Also

- gui_select_materials_of_selected

---

gui_select_pseudo_bumps_column_of_selected

Select the pseudo bumps column of the selected pseudo bumps.

Syntax

```
status gui_select_pseudo_bumps_column_of_selected
```

Description

The *gui_select_pseudo_bumps_column_of_selected* command selects the pseudo bumps column related to the currently selected pseudo bumps. It is intended for interactive usage in the GUI for the application.

Feedback

Examples

Select the pseudo bumps column of the selected pseudo bumps.

```
prompt> gui_select_pseudo_bumps_column_of_selected
```

See Also

- change_selection
- get_pseudo_bumps

---

gui_select_pseudo_bumps_of_selected

Select the pseudo bumps of the selected objects.

Syntax

```
status gui_select_pseudo_bumps_of_selected
```

Description

The *gui_select_pseudo_bumps_of_selected* command selects the pseudo bumps related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Pseudo bumps that are already selected remain selected, while bump_region, bump_region_pattern objects will have their related pseudo bumps selected.

Examples

Select the pseudo bumps of the selected objects.

```
prompt> gui_select_pseudo_bumps_of_selected
```

See Also

- change_selection
- get_pseudo_bumps

---

gui_select_pseudo_bumps_row_of_selected

Select the pseudo bumps row of the selected pseudo bumps.

Syntax

```
status gui_select_pseudo_bumps_row_of_selected
```

Feedback

Description

The *gui_select_pseudo_bumps_row_of_selected* command selects the pseudo bumps row related to the currently selected pseudo bumps. It is intended for interactive usage in the GUI for the application.

Examples

Select the pseudo bumps row of the selected pseudo bumps.

```
prompt> gui_select_pseudo_bumps_row_of_selected
```

See Also

- change_selection
- get_pseudo_bumps

---

gui_select_pseudo_tsv_defs_of_selected

Select the tsv defs of the selected objects.

Syntax

```
status gui_select_pseudo_tsv_defs_of_selected
```

Description

The *gui_select_pseudo_tsv_defs_of_selected* command selects the tsv defs related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Tsv defs that are already selected remain selected, while pseudo_tsv objects will have their related tsv_defs selected.

Examples

Select the tsv defs of the selected objects.

```
prompt> gui_select_pseudo_tsv_defs_of_selected
```

See Also

- change_selection
- get_pseudo_tsv_defs

---

gui_select_pseudo_tsvs_column_of_selected

Select the pseudo tsvs column of the selected pseudo tsvs.

Feedback

Syntax

```
status gui_select_pseudo_tsvs_column_of_selected
```

Description

The *gui_select_pseudo_tsvs_column_of_selected* command selects the pseudo tsvs column related to the currently selected pseudo tsvs. It is intended for interactive usage in the GUI for the application.

Examples

Select the pseudo tsvs column of the selected pseudo tsvs.

```
prompt> gui_select_pseudo_tsvs_column_of_selected
```

See Also

- change_selection
- get_pseudo_tsvs

---

gui_select_pseudo_tsvs_of_selected

Select the pseudo tsvs of the selected objects.

Syntax

```
status gui_select_pseudo_tsvs_of_selected
```

Description

The *gui_select_pseudo_tsvs_of_selected* command selects the pseudo tsvs related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Pseudo tsvs that are already selected remain selected, while pseudo_bump, bump_region, bump_region_pattern objects will have their related pseudo tsvs selected.

Examples

Select the pseudo tsvs of the selected objects.

```
prompt> gui_select_pseudo_tsvs_of_selected
```

See Also

- change_selection
- get_pseudo_tsvs

Feedback

gui_select_pseudo_tsvs_row_of_selected

Select the pseudo tsvs row of the selected pseudo tsvs.

Syntax

```
status gui_select_pseudo_tsvs_row_of_selected
```

Description

The *gui_select_pseudo_tsvs_row_of_selected* command selects the pseudo tsvs row related to the currently selected pseudo tsvs. It is intended for interactive usage in the GUI for the application.

Examples

Select the pseudo tsvs row of the selected pseudo tsvs.

```
prompt> gui_select_pseudo_tsvs_row_of_selected
```

See Also

gui_select_repeater_cells_of_selected

Select the buffer/inverter cells associated with selected topology repeaters of type repeater.

Syntax

```
status gui_select_repeater_cells_of_selected
```

Description

The *gui_select_repeater_cells_of_selected* command selects the buffer/inverter cells associated with currently selected topology repeaters of type repeater. It is intended for interactive usage in the GUI for the application.

Examples

Select the buffer/inverter cells associtated with selected objects.

```
prompt> gui_select_repeater_cells_of_selected
```

---

gui_select_routing_corridors_of_selected

Select the routing_corridors of the selected objects.

Syntax

```
status gui_select_routing_corridors_of_selected
```

Description

The *gui_select_routing_corridors_of_selected* command selects the routing_corridors related to the currently selected objects. It is intended for interactive usage in the GUI for the application. If there are selected net, super net, pin, port, bundle, terminal, shape, or via objects the nets associated with those objects are used to determine the associated routing corridor.

Examples

Select the routing_corridors of the selected objects.

```
prompt> gui_select_routing_corridors_of_selected
```

See Also

- change_selection
- get_routing_corridors

---

gui_select_rp_blockages_of_selected

Select the relative placement (RP) blockages of the selected objects.

Syntax

```
status gui_select_rp_blockages_of_selected
```

Feedback

Description

The *gui_select_rp_blockages_of_selected* command selects the relative placement (RP) blockages related to the currently selected objects. It is intended for interactive usage in the GUI for the application. When rp_group is selected, this command returns its RP blockage if any.

Examples

Select the RP blockages of the selected objects.

```
prompt> gui_select_rp_blockages_of_selected
```

See Also

- change_selection
- get_rp_blockages

---

gui_select_rp_groups_of_selected

Select the relative placement (RP) groups of the selected objects.

Syntax

```
status gui_select_rp_groups_of_selected
```

Description

The *gui_select_rp_groups_of_selected* command selects the relative placement (RP) groups related to the currently selected objects. It is intended for interactive usage in the GUI for the application.

When an RP blockage or cell is selected, this command returns the rp group that host the rp blockage or cell; when rp group is selected, this command returns the RP group inside it if any.

Examples

Select the RP groups of the selected objects.

```
prompt> gui_select_rp_groups_of_selected
```

See Also

- get_rp_groups
- get_rp_group_objects

Feedback

gui_select_rtl_statements_of_selected

Selects the RTL statements of the selected objects.

Syntax

```
status gui_select_rtl_statements_of_selected
```

Description

The *gui_select_rtl_statements_of_selected* command selects the RTL statements related to the currently selected objects. It is intended for interactive usage in the GUI for the application. RTL statements that are already selected remain selected, while when a cell or module is selected, this command returns their related RTL statements objects.

Examples

Select the RTL statements of the selected objects.

```
prompt> gui_select_rtl_statements_of_selected
```

See Also

- change_selection
- get_statements

gui_select_safety_core_groups_of_selected

Selects the safety core groups of the selected objects.

Syntax

```
status gui_select_safety_core_groups_of_selected
```

Description

The *gui_select_safety_core_groups_of_selected* command selects the safety core groups related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Safety core groups that are already selected remain selected, while when a cell or safety core rule object is selected, this command returns their related safety core groups.

Examples

Select the safety core groups of the selected objects.

```
prompt> gui_select_safety_core_groups_of_selected
```

Feedback

See Also

- change_selection
- get_safety_core_groups

---

gui_select_safety_core_rules_of_selected

Selects the safety core rules of the selected objects.

Syntax

```
status gui_select_safety_core_rules_of_selected
```

Description

The *gui_select_safety_core_rules_of_selected* command selects the safety core rules related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Safety core rules that are already selected remain selected, while when a cell or safety core group object is selected, this command returns their related safety core rules.

Examples

Select the safety core rules of the selected objects.

```
prompt> gui_select_safety_core_rules_of_selected
```

See Also

- change_selection
- get_safety_core_rules

---

gui_select_safety_error_code_groups_of_selected

Selects the safety error code groups of the selected objects.

Syntax

status *gui_select_safety_error_code_groups_of_selected*

Arguments

This command has no arguments.

Description

The *gui_select_safety_error_code_groups_of_selected* command selects the safety error code groups related to the currently selected objects. It is intended for interactive usage

Feedback

in the GUI for the application. Safety error code groups that are already selected remain selected, while when a safety error code rule object is selected, this command returns their related safety error code groups.

Examples

Select the safety error code groups of the selected objects.

```
prompt> gui_select_safety_error_code_groups_of_selected
```

See Also

- gui_select_safety_error_code_rules_of_selected

gui_select_safety_error_code_rules_of_selected

Selects the safety error code rules of the selected objects

Syntax

status *gui_select_safety_error_code_rules_of_selected*

Arguments

This command has no arguments.

Description

The *gui_select_safety_error_code_rules_of_selected* command selects the safety error code rules related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Safety error code rules that are already selected remain selected, while when a safety error code group object is selected, this command returns their related safety error code rules.

Examples

Select the safety error code rules of the selected objects.

```
prompt> gui_select_safety_error_code_rules_of_selected
```

See Also

- gui_select_safety_error_code_groups_of_selected

gui_select_safety_register_groups_of_selected

Selects the safety register groups of the selected objects.

Feedback

Syntax

```
status gui_select_safety_register_groups_of_selected
```

Description

The *gui_select_safety_register_groups_of_selected* command selects the safety register groups related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Safety register groups that are already selected remain selected, while when a cell or safety register rule object is selected, this command returns their related safety register groups.

Examples

Select the safety register groups of the selected objects.

```
prompt> gui_select_safety_register_groups_of_selected
```

See Also

- change_selection

---

gui_select_shapes_of_selected

Select the shapes of the selected objects.

Syntax

```
status gui_select_shapes_of_selected
```

Description

The *gui_select_shapes_of_selected* command selects the shapes of the currently selected objects. It is intended for interactive usage in the GUI for the application. Shapes that are

Feedback

already selected remain selected, while bound, voltage_area, routing_corridor, and port, objects will have their related shapes selected.

Examples

Select the shapes of the selected objects.

```
prompt> gui_select_shapes_of_selected
```

See Also

- change_selection

---

gui_select_shield_routing_of_selected

Select the shield routes and vias related to the selected signal nets, vias or routes.

Syntax

```
status gui_select_shield_routing_of_selected
```

Description

The *gui_select_shield_routing_of_selected* command selects the shield routing for the nets of the currently selected objects. It is intended for interactive usage in the GUI for the application.

Examples

Select the shield routing of the selected objects.

```
prompt> gui_select_shield_routing_of_selected
```

See Also

- gui_select_shielded_nets_of_selected

Feedback

gui_select_shielded_nets_of_selected

Select the signal nets that the selected objects are shielding.

Syntax

```
status gui_select_shielded_nets_of_selected
```

Description

The *gui_select_shielded_nets_of_selected* command selects the shielded nets related to the currently selected shield routes. It is intended for interactive usage in the GUI for the application.

Examples

Select the shielded nets of the selected shield routes.

```
prompt> gui_select_shielded_nets_of_selected
```

- gui_select_shield_routing_of_selected

gui_select_site_arrays_of_selected

Select the site arrays of the selected objects.

Syntax

```
status gui_select_site_arrays_of_selected
```

Description

The *gui_select_site_arrays_of_selected* command selects the site arrays related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Site arrays that are already selected remain selected, while site rows, tracks will have their related site arrays selected.

Examples

Select the site arrays of the selected objects.

```
prompt> gui_select_site_arrays_of_selected
```

Feedback

See Also

- change_selection
- get_site_arrays
- get_site_rows
- get_tracks

---

gui_select_site_rows_of_selected

Select the site rows of the selected objects.

Syntax

```
status gui_select_site_rows_of_selected
```

Description

The *gui_select_site_rows_of_selected* command selects the site rows related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Site rows that are already selected remain selected, while site arrays will have their related site rows selected.

Examples

Select the site rows of the selected objects.

```
prompt> gui_select_site_rows_of_selected
```

See Also

- change_selection
- get_site_rows
- get_site_arrays

---

gui_select_supernets_of_selected

Select the supernets of the selected objects.

Syntax

```
status gui_select_supernets_of_selected
```

Feedback

Description

The *gui_select_supernets_of_selected* command selects the supernets related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Supernets that are already selected remain selected, while nets, pins, ports, shapes, vias, bundles, and routing corridors will have their related supernets selected.

Examples

Select the supernets of the selected objects.

```
prompt> gui_select_supernets_of_selected
```

See Also

- change_selection
- get_supernets
- get_pins

---

gui_select_tap_cells_of_selected

Selects the tap cells of the selected objects.

Syntax

```
status gui_select_tap_cells_of_selected
```

Description

The *gui_select_tap_cells_of_selected* command selects the tap cells related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Tap cells that are already selected remain selected, while when a cell or safety register group object is selected, this command returns their related tap cells.

Examples

Select the tap cells of the selected objects.

```
prompt> gui_select_tap_cells_of_selected
```

See Also

- change_selection

---

gui_select_terminals_of_selected

Select the terminals of the selected objects.

Feedback

Syntax

```
status gui_select_terminals_of_selected
```

Description

The *gui_select_terminals_of_selected* command selects the terminals related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Terminals that are already selected remain selected, while port, net, and design objects will have their related terminals selected.

Examples

Select the terminals of the selected objects.

```
prompt> gui_select_terminals_of_selected
```

See Also

- change_selection
- get_terminals

---

gui_select_topology_begin_nodes_of_selected

Selects the topology nodes of type begin for the selected objects.

Syntax

```
status gui_select_topology_begin_nodes_of_selected
```

Description

The *gui_select_topology_begin_nodes_of_selected* command selects the begin nodes related to the currently selected objects, with whom the same nets are shared. It is intended for interactive usage in the GUI for the application. Cell, net, terminal, port, pin, topology node, and topology edge objects will have their related topology nodes selected.

Examples

Select the topology begin nodes of the selected objects.

```
prompt> gui_select_topology_begin_nodes_of_selected
```

See Also

- change_selection
- get_topology_edges
- get_topology_nodes

Feedback

- gui_select_topology_nodes_of_selected

---

gui_select_topology_edges_of_selected

Selects the topology edges of the selected objects.

Syntax

```
status gui_select_topology_edges_of_selected
```

Description

The *gui_select_topology_edges_of_selected* command selects the edges related to the currently selected objects, with whom the same nets are shared. It is intended for interactive usage in the GUI for the application. Cell, net, terminal, port, pin, topology node, and topology edge objects will have their related topology edges selected.

Examples

Select the topology edges of the selected objects.

```
prompt> gui_select_topology_edges_of_selected
```

---

gui_select_topology_end_nodes_of_selected

Selects the topology nodes of type end for the selected objects.

Syntax

```
status gui_select_topology_end_nodes_of_selected
```

Feedback

Description

The *gui_select_topology_end_nodes_of_selected* command selects the end nodes related to the currently selected objects, with whom the same nets are shared. It is intended for interactive usage in the GUI for the application. Cell, net, terminal, port, pin, topology node, and topology edge objects will have their related topology nodes selected.

Examples

Select the topology end nodes of the selected objects.

```
prompt> gui_select_topology_end_nodes_of_selected
```

- gui_select_topology_edges_of_selected

---

gui_select_topology_plans_of_selected

Selects the topology plans of the selected objects.

Syntax

```
status gui_select_topology_plans_of_selected
```

Description

The *gui_select_topology_plans_of_selected* command selects the topology plans related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Topology node, edge, and repeater objects will have topology plans which own these objects selected.

If the objects are nets, supernets, or bundles, the command selects the topology plans that have one or more of those objects in their "objects" attribute collection.

Examples

Select the topology plans of the selected objects.

```
prompt> gui_select_topology_plans_of_selected
```

---

gui_select_topology_repeaters_of_selected

Selects the topology repeaters of the selected objects.

Feedback

Syntax

```
status gui_select_topology_repeaters_of_selected
```

Description

The *gui_select_topology_repeaters_of_selected* command selects the repeaters related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Topology plan and topology edge objects will have their related topology repeaters selected.

Examples

Select the topology repeaters of the selected objects.

```
prompt> gui_select_topology_repeaters_of_selected
```

---

gui_select_tracks_of_selected

Select the tracks of the selected objects.

Syntax

```
status gui_select_tracks_of_selected
```

Description

The *gui_select_tracks_of_selected* command selects the tracks related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Tracks that are already selected remain selected, while site arrays will have their related tracks selected.

Examples

Select the tracks of the selected objects.

Feedback

```
prompt> gui_select_tracks_of_selected
```

See Also

- change_selection
- get_site_arrays
- get_tracks

---

gui_select_via_ladders_of_selected

Select the via ladders of the selected objects.

Syntax

```
status gui_select_via_ladders_of_selected
```

Description

The *gui_select_via_ladders_of_selected* command selects the via ladders related to the currently selected objects. It is intended for interactive usage in the GUI for the application. While pin objects are selected, their related via ladders will be selected.

Examples

Select the via ladders of the selected objects.

```
prompt> gui_select_via_ladders_of_selected
```

See Also

- change_selection
- get_via_ladders

---

gui_select_vmbucket

Select the Contents of a Visual Mode Bucket

Syntax

string *gui_select_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-replace | -add | -remove]

```
string  mode_identifier
string  bucket_identifier
```

Feedback

Arguments

`-vmname` *`mode_identifier`*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes, use the *gui_list_vm* command.

`-name` *`bucket_identifier`*

Specifies the name of the visual mode bucket.

`-replace`

Optional argument that indicates that the contents of the visual mode bucket will replace the selection list.

`-add`

Optional string that indicates that the contents of the visual mode bucket will be added to the selection list.

`-remove`

Optional string that indicates the contents of the visual mode bucket will be removed from the selection list.

Description

The *gui_select_vmbucket* command selects the contents of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The contents of the visual mode bucket can replace, be added to, or be removed from the selection list.

Examples

Select the 2nd bucket of SNAPSHOT visual mode.

shell> *gui_select_vmbucket -vmname SNAPSHOT -name 1 -replace*

See Also

- gui_create_vm
- gui_get_vm

Feedback

- gui_set_vmbucket
- gui_update_vm

---

gui_select_voltage_areas_of_selected

Select the voltage areas of the selected objects.

Syntax

```
status gui_select_voltage_areas_of_selected
```

Description

The *gui_select_voltage_areas_of_selected* command selects the voltage_areas related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Vias that are already selected remain selected, while voltage_area_shape objects will have their related voltage_areas selected.

Examples

Select the voltage_areas of the selected objects.

```
prompt> gui_select_voltage_areas_of_selected
```

See Also

- change_selection
- get_voltage_areas

---

gui_select_voting_logics_of_selected

Selects the voting logics of the selected objects.

Syntax

```
status gui_select_voting_logics_of_selected
```

Description

The *gui_select_voting_logics_of_selected* command selects the voting logics related to the currently selected objects. It is intended for interactive usage in the GUI for the application. Voting logics that are already selected remain selected, while for cell, safety core group, and safety register group objects, this command selects their related voting logics.

Examples

Select the voting logics of the selected objects.

Feedback

```
prompt> gui_select_voting_logics_of_selected
```

See Also

- change_selection

---

gui_selection_stack

Command to manipulate selection stack

Syntax

```
status gui_selection_stack
{ -push | -pop | -clear | -get n | -remove n | -list }
```

Arguments

`-push`

Push the global selection onto the top of the selection stack

`-pop`

Pop the selection from the top of the selection stack and make it the global selection.

`-clear`

Clear the selection stack.

`-get n`

Get the nth element of the selection stack.

`-remove n`

Remove the nth element of the selection stack.

`-list`

List the selection stack.

Description

Allows the user to push the global selection onto a stack to be popped off later.

Note: The selection stack has a maximum depth (default 10) to prevent the stack getting too large. Any selection pushed onto the stack when it is full will remove the oldest (bottommost) entry in the stack.

The 'gui_selection_stack_depth' variable can be set to change the depth.

Feedback

Examples

The following example pushes the global selection to the stack, clears the global selection, and restores the pushed selection.

```
shell> gui_selection_stack -push
shell> change_selection
shell> gui_selection_stack -pop
```

See Also

- gui_selection_stack
- gui_selection_stack_depth

---

gui_set_active_window

Make the specified window the active window

Syntax

```
status gui_set_active_window
-window window_id
```

Data Types

```
window_id    string
```

Arguments

`-window window_id`

Specifies the window name id.

The matching window of this id will be made the active window.

Note: both toplevel windows and child windows of a particular toplevel window have a currently active window. If the window is a toplevel window then the currently active toplevel window is changed, of the window is a child window the currently active child window in the specified window's parent is changed.

Description

This command makes the specified window the active window.

Examples

The following example will make the toplevel window Toplevel.2 active.

```
shell> gui_set_active_window -window Toplevel.2
```

Feedback

See Also

- gui_close_window
- gui_exist_window
- gui_show_window
- gui_get_window_types
- gui_get_window_ids
- gui_create_window
- gui_get_current_window

---

gui_set_bucket_option

Sets the value for an option on a bucket in the specified visual mode or map mode.

Syntax

```
string gui_set_bucket_option
-map map_name
-bucket bucket_name
-option option_name
-value value | -default
```

Data Types

```
map_name          string
bucket_name       string
option_name       string
value             string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-bucket bucket_name`

Specifies the name of the bucket.

`-option option_name`

Specifies the name of the option to be set.

`-value value`

Specifies the value for the option.

Feedback

The *-value* option is mutually exclusive with the *-default* option. You must use one, but not both.

`-default`

Sets the option to its default value.

The *-default* option is mutually exclusive with the *-value* option. You must use one, but not both.

Description

This command sets the value for an option on a bucket in a visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. You must set the option to either a specific value or its default value. Use the *-value* option to set a specific value or use the *-default* option to set the option to its default value.

Examples

The following example sets the color of *bucket1* to yellow in the global route congestion map:

```
prompt> gui_set_bucket_option -map AREAPARTITION \\
        -bucket bucket1 -option color -value yellow
```

See Also

- gui_get_bucket_option
- gui_get_bucket_option_list
- gui_get_map_list
- gui_get_map_option
- gui_get_map_option_list
- gui_set_map_option

---

gui_set_charts_data

Set charts data

Syntax

```
status gui_set_charts_data
{ -global | -model model_id | -view view_name |
-plot plot_name | -annotation string }
[ -column int ]
[ { -header | -row int } ]
-name string
```

Feedback

```
-value string
[ -data string ]
```

Data Types

```
model_id   int
view_name  string
plot_name  string
```

Arguments

`-global`

Set global data.

`-model model_id`

Model to set data in.

`-view view_name`

View to set data in.

`-plot plot_name`

Plot to set data in.

`-annotation string`

Set annotation data

`-column int`

Column to set model data in.

Only used by the *model* option.

`-header`

Set model header data.

Only used by the *model* option.

`-row int`

Row to set model data in.

Only used by the *model* option.

`-name string`

Name of data to set.

Feedback

The supported names depend on which object the data is being set in:

For model the following names are supported:

value Set value of model horizontal header or row value.

column_type Set specific column type or all model column types. If the column is specified then this is the type for the specified column, if no column is specified this is a list of types for the model's columns. See *gui_create_charts_model column_type* for details of the syntax.

name Set model name.

For view the following names are supported:

fit fit plots in the view.

For plot no names are currently supported:

For global no names are currently supported:

`-value` *`string`*

The value to set.

`-data` *`string`*

Extra data value

Description

Set data in model, view, plot or globally.

If model is specified then the *column* and *header* or *row* should be specified.

Examples

The following example sets the name of a model.

```
shell> gui_set_charts_data -model $model -name "Test Model"
```

See Also

- gui_get_charts_data

---

gui_set_charts_property

Set charts property

Syntax

```
status gui_set_charts_property
{ -view view_name | -plot plot_name |
```

Feedback

```
-annotation annotation_id }
[-plot_type plot_type]
-name string
-value string
```

Data Types

```
view_name       string
plot_name       string
annotation_id   string
plot_type       string
```

Arguments

`-view view_name`

View to set property in.

`-plot plot_name`

Plot to set property in.

`-annotation annotation_id`

Plot annotation to set property in.

`-plot_type plot_type`

Type of plot to set property in.

`-name string`

Name of property to set.

The supported names depend on which object the data is being set in:

`-value string`

The value to set.

Description

Set property of view, plot or plot annotation.

Examples

The following example sets the line stroke color of a plot to red.

```
shell> gui_set_charts_property -plot $plot -name "stroke.color" -value
 red
```

See Also

- gui_get_charts_property

Feedback

gui_set_current_errors

Sets the current error data and the current error group in the Error Browser.

Syntax

string *gui_set_current_errors*

[-data_name *ErrorDataName*] [-group *Group*] [-sub_group *SubGroup*]

```
ErrorDataName       String
Group          String
SubGroup       String
```

Arguments

`-data_name` *ErrorDataName*

ErrorDataName specifies the error data to make current. The error data name may be omitted. If omitted, makes all open error data current.

`-group` *Group*

Group specifies the group name, either a layer name or error type name, to make current. The group name may be omitted. If omitted, an entire error data file is made current.

`-sub_group` *SubGroup*

SubGroup specifies a sub-group name, either a layer name or error type name, to make current. If omitted, all sub-groups for the group are made current.

Description

Sets the current error data and the current error group in the Error Browser. This is analogous to selecting error data and group in the Error Browser tree view. By default, there is are no current errors. The current errors determine the errors that are displayed in the error list and in the layout view by default.

If the error data option is omitted, selects the design, the parent of all open error data. The group option is valid only when there is a single error data specified, and raises an error if no error data was specified. The group string is interpreted as error type if error grouping has been set to *type*, else the group string is interpreted as layer. If the group option is omitted, all groups in the specified error data are made current.

Examples

The following example sets error grouping by error type, and sets the "Open Locator" type errors for LVS error data as the current errors:

gui_set_error_browser_option -grouping type gui_set_current_errors -data_name LVS -group "Open Locator"

Feedback

The following example sets the design as current, displaying all errors in all open error data in the error list and layout view.

gui_set_current_errors

See Also

- gui_error_browser
- gui_set_selected_errors

---

gui_set_current_task

Set current task to the given task.

Syntax

string *gui_set_current_task* -name *task_name*

-task *task_name*

`string task_name`

Arguments

`-task task_name`

Specifies the name of the task to make current.

Description

The gui_set_current_task command sets the current application task to the given task.

See Also

- gui_create_task
- gui_get_current_task
- gui_get_task_list

---

gui_set_display_view

Sets the display view type (abstract, design, frame, layout, or outline) used in the layout when cell-specific views are active. Views are returned with the *gui_get_display_view* command.

Syntax

string *gui_set_display_view*

Feedback

```
-cells cell_list
-view view_name
```

Data Types

```
cell_list  list
view_name  string
```

Arguments

`-cells cell_list`

Specifies the physical cells for which to set the view.

`-view view_name`

Specifies the view name. Accepted view names are abstract, design, frame, layout, outline, and the empty string {}.

Description

This command sets the display view type for the specified cell. The layout can display the contents of cells when the view level is set to a value greater than 1. Normally the displayed information is for the bound (or linked) view for the reference block. The layout also supports globally displaying an alternate view (for example the design view if the block is bound to abstracts) and a cell-specific view setting. Use this command to change the displayed view on a cell-by-cell basis.

If the specified view does not exist, then the layout will display the currently bound view.

This setting also controls the edit-in-place operation in the layout. The currently displayed view is always used.

Examples

The following example sets the design view for cell I_ORCA_TOP/I_BLENDER_4. When a block is bound to abstract views, you can display the design view for certain cells in order to fix DRC errors.

```
prompt> gui_set_display_view -cells I_ORCA_TOP/I_BLENDER_4 -view design
```

The following example resets the display view to the default by specifying an empty value.

```
prompt> gui_set_display_view -cells I_ORCA_TOP/I_BLENDER_4 -view {}
```

See Also

- gui_get_display_view

Feedback

gui_set_error_browser_option

Sets options for the Error Browser dialog box.

Syntax

string *gui_set_error_browser_option*

[-grouping *Group*] [-show_mode *ShowMode*] [-view_mode *ViewMode*] [-zoom_factor *ZoomFactor*] [-hide_fixed *DoHide*] [-hide_ignored *DoHide*] [-hide_waived *DoHide*] [-hide_null_net *DoHide*] [-autoselect_first_error_id *DoAutoselect*] [-advance_to_next_unfixed *DoNext*] [-dim *DoDim*] [-show_open_locator_nodes *DoShow*] [-show_tooltip *DoShow*] [-show_command_buttons *DoShow*] [-highlight_objects *DoHighlight*] [-auto_set_object_visible *SetVisible*] [-auto_set_object_visible_type *SetVisibleType*]

```
Group              String
ShowMode           String
ViewMode           String
ZoomFactor         float
DoHide             Boolean
DoNext             Boolean
DoDim              Boolean
DoShow             Boolean
DoHighlight        Boolean
DoAutoselect       Boolean
SetVisible         Boolean
SetVisibleType     String
```

Arguments

`-grouping` *Group*

The *-grouping* option accepts argument values *type* or *layer* and sets whether errors are grouped by types or layers. This is similar to selecting or deselecting *Show by Layer* option in the Error Browser *Options* menu. By default, errors are grouped by type by default.

`-show_mode` *ShowMode*

The *-show_mode* option accepts argument values *all*, *selected*, or *none* and sets whether all errors, selected errors, are no errors are shown in layout views. This is similar to making a selection from the *Show* field in the Error Browser. The default is that all errors are shown.

`-view_mode` *ViewMode*

The *-view_mode* option accepts argument values *zoom*, *pan*, or *off* and sets the layout view to zoom to, pan to, or not change to the currently selected errors in the Error Browser. This is similar to making a selection from the *Follow* field in the Error Browser. The default is to zoom to the selected error.

Feedback

`-zoom_factor` *`ZoomFactor`*

The *-zoom_factor* option accepts float values between *0.1* and *10.0* and sets the zoom factor used when the view_mode is *zoom*. The zoom factor rounds to 1/10 precision. The default value is *1.0*.

`-hide_fixed` *`DoHide`*

The *-hide_fixed* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether fixed errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Fixed Errors* option in the Error Browser *Options* menu. By default, fixed errors are shown.

`-hide_ignored` *`DoHide`*

The *-hide_ignored* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether ignored errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Ignored Errors* option in the Error Browser *Options* menu. By default, ignored errors are shown.

`-hide_waived` *`DoHide`*

The *-hide_waived* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether waived errors are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Waived Errors* option in the Error Browser *Options* menu. By default, waived errors are shown.

`-hide_null_net` *`DoHide`*

The *-hide_null_net* option accepts Boolean values *1* or *true* to mean "hide", and *0* or *false* to mean "show". The option controls whether errors associated with null nets are hidden or shown in the Error Browser and layout views. This is similar to selecting or deselecting *Hide Null Net Errors* option in the Error Browser *Options* menu. By default, null net errors are shown.

`-autoselect_first_error_id` *`DoAutoselect`*

The *-autoselect_first_error_id* option accepts Boolean values *1* or *true* to mean "select first error ID", and *0* or *false* to mean "do not select first error ID". The option controls whether the first error ID in the Error Browser is automatically selected when an error set is selected in the Error Browser. This is similar to selecting or deselecting the *Auto-select First Error ID Upon Selecting Error Set* option in the Error Browser *Options* menu. By default, the first error ID is not automatically selected.

Feedback

`-advance_to_next_unfixed` *`DoNext`*

The *-advance_to_next_unfixed* option accepts Boolean values *1* or *true* to mean advance to next unfixed error when an error is fixed and *0* or *false* to advance to next fixed/unfixed error. This is similar to checking or unchecking the *Advance To Next Unfixed When Error is Fixed* option in the Error Browser. By default, unfixed errors are not advanced to.

`-dim` *`DoDim`*

The *-dim* option accepts Boolean values *1* or *true* to mean "dim" and *0* or *false* to mean "do not dim". The option governs whether layout views are dimmed when errors are displayed. This is similar to checking or unchecking the *Dim* option in the Error Browser. By default, layout views are not dimmed.

`-show_open_locator_nodes` *`DoShow`*

The *-show_open_locator_nodes* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether net nodes are highlighted together with the open locator flylines for selected open locator errors. This is similar to selecting or deselecting the *Display Net Nodes for Selected Open Locators* option in the Error Browser *Options* menu. By default, the tool does not show the net node highlights.

`-show_tooltip` *`DoShow`*

The *-show_tooltip* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether tool tips are shown on the error browser list view and details pane. By default, the tool shows the tool tips.

`-show_command_buttons` *`DoShow`*

The *-show_command_buttons* option accepts Boolean values *1* or *true* to mean "show", and *0* or *false* to mean "hide". This setting controls whether the command buttons at the bottom of the error browser are shown. By default, the tool shows the command buttons.

`-highlight_objects` *`DoHighlight`*

The *-highlight_objects* option accepts Boolean values *1* or *true* to mean "highlight", and *0* or *false* to mean "do not highlight". This setting controls whether design objects associated with the selected error are highlighted in the layout view using design object highlighting. When the error object selection changes, the highlight is automatically removed from the associated design objects. By default, the tool does not highlights associated design objects.

`-auto_set_object_visible` *`SetVisible`*

The *-auto_set_object_visible* option accepts Boolean values *1* or *true* to mean "turn on" and *0* or *false* to mean "do not turn on". The option governs whether

Feedback

relevant object visibility of layout view are turned on when errors are displayed. This is similar to checking or unchecking the *Auto Set Object Visible* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on for related error object display.

`-auto_set_object_visible_type` *`SetVisibleType`*

The *-auto_set_object_visible_type* option accepts argument values *incremental*, or *exclusive* to mean turn on layers/objects incrementally or exclusively when a different error is selected. This is similar to selecting the *Auto Set Object Visible Incremental/Exclusive* menu item in the 'Options' menu button of the Error Browser. By default, layout object visibility will be turned on incrementally for related error object display.

Description

This command sets option setting for the Error Browser. Multiple option values can be set using one command.

Examples

The following example sets the grouping of errors by layers, to show all errors, and to pan to selected errors.

```
prompt> gui_set_error_browser_option -grouping layer -show_mode all
 -view_mode pan
```

The following example sets the option to dim layout views when errors are displayed and to hide fixed errors:

```
prompt> gui_set_error_browser_option -dim true -hide_fixed true
```

See Also

- gui_error_browser
- gui_get_error_browser_option

---

gui_set_error_data_filter

Set a filter on open error data.

Syntax

string *gui_set_error_data_filter*

-show | -hide [-error_layer_strings *LayerList*] [-types *TypeList*] [-objects *ObjectCollection*] [-typed_object_names *ObjectSpecification*] [-object_types *ObjectTypeSpecification*] [-within *Rectangle*]

Feedback

```
TypeList          String List
LayerList         String List
ObjectSpec        String List or collection
ObjectCollection  collection
ObjectTypeList    String List
Rectangle         String
```

Arguments

`-show | -hide`

Mutually exclusive required option to specify whether the filtering should hide the records matching the filter criteria (-hide) or prune to the records matching the filter criteria (-show).

`-types` *`TypeList`*

Optional argument to specify a list of type names as filter criteria. An error record would match this criteria if its type attribute value matches any type name in the list.

`-error_layer_strings` *`LayerList`*

Optional argument to specify a list of layer strings as filter criteria. An error record would match this criteria if its layer string matches any layer string in the list. The layer strings is the layer_names string attribute value for the error. It is is also displayed in the error browser.

`-objects` *`ObjectCollection`*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects,such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any object in the collection. Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects".

`-typed_object_names` *`ObjectSpecification`*

Optional argument to specify a set of design objects as filter criteria. An error record can be associated with zero or more design objects, such as nets, pins, and cells. An error record would match this criteria if any of its associated objects matches any objects in the specification. Specify objects with type-name, object-name-list pairs, for example

{ net { NetName1 NetName2 NetName3 {} } }.

Multilple such pairs may be listed to specify objects of multiple types as filter criteria, for example

Feedback

{ { net { Net1 Net2 Net3 {} } } { pin { PinA PinB } } }.

Associated objects for an error can be accessed using get_attribute. The attribute name is tool specific. For tools which restrict the types of object that may be associated with errors, the attribute name may be specific, such as "nets". For tools that support a more general object association, the attribute name may be more general, such as "objects". A null object association can be specified using an empty string as the object name.

`-object_types` *`ObjectTypeList`*

Optional argument to specify a list of object type names as filter criteria. An error record would match this criteria if the type attribute value of any of its associated objects matches any type name in the list.

Specify object types with type-name, type-name-list pairs, for example

{ net_type { Signal Power } }.

Multilple such pairs may be listed to specify lists for multiple object types as filter criteria, for example

{ { net_type { Signal Power } } { route_type { Detail User } } }.

`-within` *`Rectangle`*

Optional argument to specify a rectangle as filter criteria. An error record would match this criteria if its bounding box is within the specified rectangle.

Description

Set the given filter on open error data. Filter state is set and is applied on currently open error data and subsequently opened error data until cleared. When a new filter is set, the new filter overrides any previously set filter. There is no accumulation of filters.

In order to show errors that have been hidden by a previously set filter, clear the filter with gui_clear_error_data_filter.

You can either filter out errors matching the filter specification (use -hide) or prune the current errors to errors matching the filter specification (use -show).

If multiple kinds of criteria are used in a filter, then an error must satisfy each kind of criteria to be a match. For example, if a filter with both an error type list (the -types option) AND an object type list (the -object_types option) is set, then for an error to be a match for the filter, its type must be one of the types set in the filter AND its associated object type must be one of the object types set in the filter.

Examples

The following example illustrates how to show only errors of type "Short":

gui_set_error_data_filter -show -types "Short"

Feedback

The following example illustrates how to show only errors of type "Short" that are also associated with the "Signal" net type:

gui_set_error_data_filter -show -types "Short" -object_types {{net_type "Signal"}}

The following example illustrates how to hide errors associated with the "Global" route type:

gui_set_error_data_filter -hide -object_types {{route_type {Global}}}

The following example shows how to clear the error data filter:

gui_clear_error_data_filter

See Also

- gui_error_browser
- gui_clear_error_data_filter
- gui_set_error_browser_option

---

gui_set_error_status

Set the error status value of one or more error records.

Syntax

string *gui_set_error_status*

-errors *Errors* -status *Status*

```
Errors            String
Status            Status
```

Arguments

`-errors` *`Errors`*

Errors specifies the handle for a collection of errors on which to set the fixed state.

`-status` *`Status`*

The *-status* argument specifies the status value. The supported status values are tool dependent. All tools with physical error data for the error browser support values "error" and "fixed". Some tools also support "ignored".

Description

This command sets the status of the given error objects to the given status value.

Feedback

The status of an error is displayed in the Error Browser and an error can be hidden or shown based on its status value. The status is a part of the textual report written to a file by gui_report_errors.

See Also

- gui_error_browser
- gui_set_error_browser_option

---

gui_set_focus_nets

Focuses the displayed content on the objects associated with the target net.

Syntax

```
status gui_set_focus_nets
[-clct target_collection]
[-add]
[-clear]
```

Data Types

```
target_collection  collection
```

Arguments

`-clct target_collection`

Specifies the collection of target objects. If not specified, current selection is used.

`-add`

Specifies that the currently displayed net connectivity should be appended with the net connectivity associated with the specified target objects.

`-clear`

Specifies that the currently displayed net connectivity should be cleared.

Description

The *gui_set_focus_nets* command displays the net connectivity associated with the target objects.

Examples

The following example displays net connectivity associated with the currently selected target objects.

Feedback

```
prompt> gui_set_focus_nets
```

The following example adds the net connectivity associated with the net shape named "mem_die_inst/PATH_19_33" and adds it to the currently displayed focus net connectivity.

```
prompt> gui_set_focus_nets -add -clct [get_shapes
 {mem_die_inst/PATH_19_33}]
```

---

gui_set_hierview_data

Set various state in the current or named Hierarchy View and its sub-views.

Syntax

string *gui_set_hierview_data*

```
[-view                  View_Name]
[-tree_type             Tree_Type]
[-tree_attr_group       Attr_Name]
[-tree_filter           String]
[-map_area              Attr_Name]
[-map_color             Attr_Name]
[-childlist_name        String]
[-childlist_attr_group Attr_Name]
[-childlist_filter      String]
[-elide                 Elide_Type]
View_Name      String
Attr_Name      String
Tree_Type      String (logical|rtl)
```

Arguments

`-view` *View_Name*

Use the given HierView window name (ex: Hier.1) for the following actions. Default is to get the most recent used HierView window name.

`-tree_type` *Tree_Type*

Set the current Hier Tree type to Logical or RTL hierarchy. RTL hierarchy is only available in RTLA. The default is logical.

`-tree_attr_group` *Attr_Name*

Set the current Hier Tree attribute group name.

`-tree_filter` *String*

Set the current Hier Tree filter expression.

`-map_area` *Attr_Name*

Set the Hier Map Area attribute group name.

Feedback

`-map_color` *`Attr_Name`*

Set the Hier Map Color attribute group name.

`-childlist_name` *`String`*

Set the current ChildList sub-view name.

`-childlist_attr_group` *`Attr_Name`*

Set the current ChildList attribute group name.

`-childlist_filter` *`String`*

Set the current ChildList filter expression.

`-elide` *`Elide_Type`*

Set the text elide for the view. Supported types are 'middle', 'left', 'right'.

Description

```
This command allows you to set various current Hierarchy View related
 view settings.
```

See Also

- gui_get_hierview_data

---

gui_set_highlight_options

Change the options that control highlighting.

Syntax

string *gui_set_highlight_options*

```
[-current_color color_id | -next_color | -auto_cycle_color enable]

string          color_id
bool            enable
```

Arguments

`-current_color` *`color_id`*

Changes the current highlight color to the specified value. The current highlight color is used as a default when no color is specified for some operations.

`-next_color`

Changes the current highlight color to the next color in the set of available colors. This will wrap around so that it can be used to cycle through the

Feedback

color set. The provided colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

`-auto_cycle_color` *enable*

Specify if the current color should automatically be incremented after each gui_change_highlight -add operation. The color is not advanced if an explicit color is specified with the -color option of gui_change_highlight.

Description

The gui_set_highlight_options command can be used to modify highlighting behavior.

Examples

Set the current highlight color to blue.

shell> gui_set_highlight_options -current_color blue

Enable auto cycling.

shell> gui_set_highlight_options -auto_cycle_color true

Advance to the next color.

shell> gui_set_highlight_options -next_color

See Also

- gui_change_highlight
- gui_get_highlight
- gui_get_highlight_options

---

gui_set_hotkey

Sets a key binding to a Tcl command or a menu command in a GUI window.

Syntax

string *gui_set_hotkey*

```
-hot_key key_name
-tcl_cmd command_name | -menu menu_name
[-replace]
[-delete]
[-replay_log_only]
[-window_type window_type_name | -all_window_types]

key_name              string
command_name          string
```

Feedback

```
menu_name              string
window_type_name       string
```

Arguments

`-hot_key` *key_name*

Specifies the key that you are associating with the specified command. The *key_name* is a string that contains the key name can also contain one or more modifiers. The valid modifier keys are *SHIFT*, *ALT*, and *CTRL*. You specify the modifier names by prepending them to the key name and connecting them with a plus sign (+).

If you bind an unmodified key and the shift-modified key is not bound, the binding works for both the shifted and nonshifted keys. If you set separate bindings for the shift-modified key and the unmodified key, the bindings are unique. Note that shift modifiers work only with letter keys and function keys.

Menus display the first key binding defined for a menu item. The key binding always appears in uppercase with its modifiers. For example, an unmodified accelerator for the letter "a" is shown as "A' and a shift-modified "a" (an uppercase A) is shown as "SHIFT+A."

`-tcl_cmd` *command_name*

Specifies the tool command language (Tcl) code that the tool executes when you press the key and its modifiers, if any.

The *-tcl_cmd* option and the *-menu* option are mutually exclusive.

`-menu` *menu_name*

Specifies the menu command that the tool invokes if you press the key and its modifiers, if any, when the menu command is enabled.

The *menu_name* is a string that specifies the hierarchy of the menu labels, with the labels connected by arrows formed from a hyphen and a greater than sign (->). For example, "File->Exit" specifies the Exit command on the File menu. The *menu_name* can also include the mnemonic for the menu text, which is specified with an embedded ampersand (&), but they are not required to do so.

The *-menu* option and the *-tcl_cmd* option are mutually exclusive.

`-replace`

Replaces an existing key binding for the specified menu command or Tcl command with the specified key.

`-delete`

Removes the key binding from the specified menu command or Tcl command.

Feedback

`-replay_log_only`

Limits logging of the Tcl command associated with the key to the command replay log file. The tool suppresses the command echo and result display to the xterm and console, and the command does not appear in the output log or the Tcl history log.

The tool ignores this option if you do not specify the *-tcl_cmd* option.

`-window_type` *`window_type_name`*

Specifies the type of top-level window that the key should apply to. (A top-level window is a window with a menu bar.) If you do not specify this option, the tool uses the application default window type.

The read-only variable *gui_default_window_type(3)* specifies the application default window type.

`-all_window_types`

Sets the key binding in every type of window for which it is applicable.

For menu command key bindings, the tool searches all of the top-level windows for the specified menu command and adds the key binding in any window where it exists. If the tool does not find any applicable windows, it issues a warning.

For Tcl command key bindings, the tool adds the binding in every type of top-level window.

Description

This command binds a given key to a function in the graphical user interface (GUI). The function might be available on a menu or specified by Tcl code. A menu command can have multiple key bindings. Key bindings can be specified for built-in or user-defined menu commands.

Key bindings for menu commands have several additional features that Tcl command key binding do not have. The function for a menu command key binding is invoked only when the menu command is enabled. This ensures that the function is invoked only when it is valid to invoke the function. In addition, the primary key bindings for menu commands appear with the menu text to make it easier for you to remember the bindings.

Examples

The following example creates a menu item and adds an additional key binding to it.

```
prompt> gui_create_menu -menu "&Test->Sub&Menu->Echo Hi" \
   -tcl_cmd "echo hi" -hot_key "Ctrl+5"
prompt> gui_set_hotkey -menu "Test->SubMenu->Echo Hi" \
   -hot_key "Ctrl+Y"
```

Feedback

The following example creates a key binding, P, that invokes a Tcl command to print a query on the currently selected objects.

```
prompt> gui_set_hotkey -tcl_cmd {query_objects [get_selection]} \
   -key P
```

---

gui_set_image_view_data

Set data on images in image view

Syntax

```
status gui_set_image_view_data
-window window_name
{ -global | -image image_name }
-name string
-value string
[ -data string ]
```

Data Types

```
window_name  string
image_name   string
```

Arguments

`-window window_name`

Specifies the name of the image view to set the data in.

`-global`

Specifies that a global value is being set.

Feedback

`-image` *`image_name`*

Specifies that value is being set for the specifed image.

`-name` *`string`*

Specifies the name of the global or image value being set.

Global Names

proc, layout, scale, scale_fit, diff, diff_auto_load, diff_scale, diff_scale_fit, movie, movie_auto_load, movie_scale, movie_delay, movie_scale_fit, movie_state, movie_frame, common_scale

proc

Specifies the tcl proc to be called when the user interacts with an image. The procedure is passed the four arguments:

- operation : operation performed by user. In current code this is always click.
- image : image id of operation.
- x : x view coordinate of operation.
- y : y view coordinate of operation.

The information passed to the proc can be used to cross reference into the associated design data of the image.

layout

Specifies the layout to use for the images part of the view.

Value is one of: horizontal, vertical, grid or stacked.

scale

Specifies the scale factor to use for the images part of the view.

Value should be greater than 0.0 and not too large so scaled image does not use too much memory.

scale_fit

If the boolean value is true then the images in the images part of the view will be scaled to fit view area.

If the boolean value is false then the image scale will be reset to 1.0 (no scaling).

diff

The boolean value specifies whether the diff area of the view is visible or not.

Feedback

diff_auto_load

The boolean value specifies whether the diff area is auto loaded with default image indices when first displayed.

diff_scale

Specifies the scale factor to use for the diff part of the view.

Value should be greater than 0.0 and not too large so scaled image does not use too much memory.

diff_scale_fit

If the boolean value is true then the images in the diff part of the view will be scaled to fit view area.

If the boolean value is false then the diff scale will be reset to 1.0 (no scaling).

movie

The boolean value specifies whether the movie area of the view is visible or not.

movie_auto_load

The boolean value specifies whether the movie area is auto loaded with first image frame when first displayed.

movie_scale

Specifies the scale factor to use for the movie part of the view.

Value should be greater than 0.0 and not too large so scaled image does not use too much memory.

movie_scale_fit

If the boolean value is true then the images in the movie part of the view will be scaled to fit view area.

If the boolean value is false then the movie scale will be reset to 1.0 (no scaling).

movie_state

Sets the movie state.

Value is one of: play, step, pause.

movie_frame

Sets the movie frame number.

Value should be 1 to number of images shown in movie area.

Feedback

common_scale

Sets that all images should use a common scale.

If multiple images are from different designs then the coordinate ranges may be different. This option scales the images so they are all drawn as if they were in a region that is the union of all the images scales.

Image Names

title, selected, value, diff_src, diff_dest

title

Sets the title string for the specified image.

selected

Sets the boolean selection state of the specified image.

value

Sets the value of the name attribute of the specified image.

In this case the -value option provides the attribute name and the -data option provides the attribute value.

diff_src

Sets the image as the source image for the diff region.

diff_dest

Sets the image as the destination image for the diff region.

`-value` *`string`*

Specifies the new value for the global or image data.

`-data` *`string`*

Specifies extra data for the global or image data.

See details on individual value names to see if this is needed or not.

Description

The *gui_set_image_view_data* command sets global or individual data values for images in the image view.

Examples

The following example sets the tcl proc for the current view which output the click point in view coordinated.

Feedback

```
shell> proc click_proc { op image x y } {
shell>   echo "$x $y"
shell> }
shell> set view [gui_get_current_window -type ImageView]
shell> gui_set_image_view_data -window $view -global -name proc -value
 click_proc
```

- gui_get_image_view_data
- gui_get_current_window

---

gui_set_layer_widths

Sets values in a list of widths per layer used for route editing.

Syntax

```
status gui_set_layer_widths
-layer layer_name
{ -clear | -values layer_widths }
```

Data Types

```
layer_name    string
layer_widths  list
```

Arguments

`-layer layer_name`

Specifies the routing layer for which to define the user widths.

`-clear`

Clears the list of user widths for the layer.

After the user widths are cleared, the *gui_get_layer_widths* command returns the default widths for the layer when the *-current* option is specified.

`-values layer_widths }`

Specifies a list of user widths to add to the current list of widths for the layer.

The list of layer widths is automatically sorted and uniquified.

If no user widths are currently defined, these values will be the only ones returned by *gui_get_layer_widths* when the *-current* option is specified.

Feedback

Description

This command defines a list of discrete layer widths to be used for routing in the route editor.

Examples

The following example specifies the set of widths for the layer 'M1'.

```
prompt> gui_set_layer_widths -layer M1 -values {0.1 0.2 0.4 0.8 1.6}
```

See Also

- gui_get_layer_widths

---

gui_set_layout_layer_visibility

Set the visibility of layers in a layout window

Syntax

```
status gui_set_layout_layer_visibility
collection_of_layers
[-window windowID]
-toggle | -only
```

Data Types

```
string windowID
```

Arguments

collection_of_layers

The collection of layers or list of layer names provided in technology file.

`-window` *windowID*

This specifies the window to have its mode changed. If not specified then the currently active window will be used.

`-toggle`

Toggle the visibility of the specified layers. The option is mutually exclusive with -only.

`-only`

Turn off all layers and then turn on only the specified layers. The option is mutually exclusive with -toggle.

Feedback

Description

This command is used to set visibility of layers in a layout view.

Examples

To turn on visibility of METAL2, METAL3 layers only:

```
shell-t> gui_set_layout_layer_visibility {METAL2 METAL3} -only -window
 Layout.1
1
```

To toggle visibility of layer METAL3:

```
shell-t> gui_set_layout_layer_visibility {METAL3} -toggle -window
 Layout.1
1
```

See Also

- gui_set_setting

---

gui_set_layout_user_command

Set user defined command for layout input.

Syntax

status *gui_set_layout_user_command*

```
-apply_cmd TclCmd | -clear
[-input_type InputType]
[-snap_type SnapType]
[-status_text string]
[-cancel_cmd TclCmd]
```

Data Types

```
TclCmd    string
InputType one of [rectangle | line | polygon | point]
SnapType  one of [litho | site | midsite | wiretrack | midwiretrack |
 user]
```

Arguments

`-apply_cmd` *TclCmd*

The user procedure to be called when input completed. The coordinates will be passed as an argument to this procedure. The options is mutually exclusive with -clear.

Feedback

`-clear`

Cancel all pending input and return layout to default mouse mode. The options is mutually exclusive with -apply_cmd.

`-input_type` *`InputType`*

The desired input type: rectangle | line | polygon | point. Default is rectangle

`-snap_type` *`SnapType`*

The desired snap type: litho | site | midsite | wiretrack | midwiretrack | user Default is litho

`-status_text` *`string`*

The help string to be shown in layout window status bar.

`-cancel_cmd` *`TclCmd`*

The user procedure to be called when input is canceled.

Description

This command is used to facilitate creation of user defined tools to extend the layout view standard capabilities. The command sets layout view to given input mode and executes user callback procedure on input complete. The input points are passed as an argument to user callback.

Examples

Cut the object shape with user specified rectangle

```
proc my_cut_object_shape_proc { rect } {
  change_selection [cut_objects [get_selection] -bbox {$rect}]
}

gui_set_layout_user_command -apply_cmd {my_cut_object_shape_proc}
 -status_text "Drag the rectangle to cut selected objects" -input_type
 rectangle
1
```

See Also

- get_selection

---

gui_set_map_option

Sets the value for an option in the specified visual mode or map mode.

Feedback

Syntax

```
string gui_set_map_option
-map map_name
-option option_name
-value value | -default
```

Data Types

```
map_name        string
option_name     string
value           string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-option option_name`

Specifies the name of the option to be set.

`-value value`

Specifies the value for the option.

The *-value* option is mutually exclusive with the *-default* option. You must specify one, but not both.

`-default`

Sets the option to its default value.

The *-default* option is mutually exclusive with the *-value* option. You must specify one, but not both.

Description

This command sets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You must set the option to a specific value or its default value. Use the *-value* option to set a specific value or the *-default* option to set the option to its default value.

Examples

The following example sets the number of bins to 9 in the global route congestion map:

```
prompt> gui_set_map_option -map AREAPARTITION \\
        -option num_bins -value 9
```

Feedback

- gui_get_bucket_option_list
- gui_get_map_list
- gui_get_map_option
- gui_get_map_option_list
- gui_set_bucket_option

---

gui_set_mouse_tool_option

Set an option on a mouse tool

Syntax

string *gui_set_mouse_tool_option* -tool *string*

-option *string* -value *string* -default -all

```
string string
string string
string string
```

Arguments

`-tool string`

Tool to set option for.

`-option string`

Option to set.

`-value string`

New option value.

`-default`

Reset the option to its default value.

`-all`

Apply to all tool options.

Description

This command sets a mouse tool option. Mouse tool options influence the operation of the mouse tool when that tool is active

Feedback

Examples

```
> gui_set_mouse_tool_option -tool SELECT -option InputMode -value
 Rectangle
```

See Also

- gui_mouse_tool
- gui_get_mouse_tool_option

---

gui_set_performance_log_option

Configures performance log behavior of logging specific commands or all default commands

Syntax

```
status gui_set_performance_log_option
[-commands command_names | -log_all]
[-add | -remove]
```

Data Types

```
command_names          list
```

Arguments

`-commands` *command_names*

This option is mutually exclusive -log_all. If -add or -remove are not given, the argument sets or refreshes the commands to be logged. If a logging process has not been started, this argument sets the specific commands to be logged for the upcoming logging process. If already been started, this argument refreshes the commands to be logged from now on.

If -add or -remove are given, the argument set the commands to be added to or removed from already existing commands list.

`-add`

This option is mutually exclusive with -remove and must be used with -commands. Use -add to add commands to the already existing commands list which is set by this command. If there is no existing commands list, this argument generates a commands list to be logged.

`-remove`

This option is mutually exclusive with -add and must be used with -commands. Use -remove to remove commands from the already existing commands list which is set by this command.

Feedback

`-log_all`

This option is mutually exclusive with -commands. This option resets the commands to be logged as default.

Description

This command controls the performance log behavior of logging specific commands or all default commands. After execute option -commands, the default commands list is not effective until execute option -log_all. The commands to be logged can be reset as default by option -log_all. This command can be used before and during a logging process and change the commands to be logged. After successfully execute this command, the logging behavior changes.

Examples

```
Configure log behavior which logs performance data before and after
 executing
commands of gui_zoom and win_select_object.

prompt> gui_set_performance_log_option -commands {gui_zoom
 win_select_objects}

Add command gui_get_current_window to the already existing commands list.

prompt> gui_set_performance_log_option -commands {gui_get_current_window}
 -add

Remove command gui_get_current_window from the already existing commands
 list.

prompt> gui_set_performance_log_option -commands {gui_get_current_window}
 -remove

Reset the log behavior which logs performance data of all default
 commands.

prompt> gui_set_performance_log_option -log_all
```

See Also

- gui_log_performance
- gui_get_performance_log_option

---

gui_set_pref_value

Set the value of a preference key.

Feedback

Syntax

string *gui_set_pref_value* -key *Key* -value *Value*

```
[-category Category]

Key             String
Value           Depends on the data type of the value of the specified
 key
Category        String
```

Arguments

`-key Key`

Key specifies the key to set the new value.

`-value Value`

Value specifies the new value of the key. The new value should be of the same data type, one of (integer,bool,double,color,string) as the data type of the value of the key.

`-category Category`

Category specifies the category that owns the specified key. If not specified, a default category will be used.

Description

This command set the value of a preference key. Returns the value of the preference key.

Examples

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command *gui_set_pref_value* is then used to change the value of the preference key to true.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool
 -value false
gui_set_pref_value -category my_category -key some_key -value true
```

See Also

- gui_create_pref_category
- gui_create_pref_key
- gui_get_pref_value
- gui_get_pref_value_type

Feedback

- gui_remove_pref_key
- gui_get_pref_categories
- gui_get_pref_keys
- gui_exist_pref_category
- gui_exist_pref_key
- gui_update_pref_file

---

gui_set_preset

Sets the specified preset for object specified by category

Syntax

```
status gui_set_preset
-category category
[-system]
[-shared]
-default
-name name
```

Data Types

```
category    string
name         string
```

Arguments

`-category` *category*

Specifies the name of the category that the presets be applied to.

`-system`

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

`-shared`

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

`-default`

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

Feedback

`-name name`

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

Description

This command applies the default or specified preset to a category.

Examples

The following example applies the system presets 'floorplan' to the Layout.

```
prompt> gui_set_preset -category Layout -name floorplan -system
```

See Also

- gui_get_presets

---

gui_set_region

Sets the coordinates of the current region rectangle or rectilinear polygon.

Syntax

string *gui_set_region* [-point *point*]

[-line *line*] [-rectangle *rectangle*] [-rectilinear *rectilinear polygon*] [-polygon *any angle polygon*] [-path *path*] [-clear] [*shape*]

```
point point
line line
rect rectangle
string rectilinear polygon
string any angle polygon
string path
string shape
```

Arguments

`-point point`

For a point, the values should be given in the following format: x1 y1

`-line line`

For a line, the values should be given in the following format: {x1 y1} {x2 y2}

`-rectangle rectangle`

For a rectangle, the values should be given in the following format: {x1 y1} {x2 y2}

Feedback

`-rectilinear` *rectilinear*

For a rectilinear polygon, the values should be given in the following format: {x1 y1} {x2 y2} ... {xN yN}

`-polygon` *any*

For an any angle polygon, the values should be given in the following format: {x1 y1} {x2 y2} ... {xN yN}

`-path` *path*

For a path, the values should be given in the following format: {x1 y1} {x2 y2} ... {xN yN}

`-clear`

Clear the region

shape

Auto detect the region type by points specified: {{x1 y1}{x2 y2} ... {xN yN}}

Description

The *gui_set_region* command sets the coordinates of the current region rectangle or rectilinear polygon in the GUI. The region can be defined using various shapes such as points, lines, rectangles, rectilinear polygons, any angle polygons, or paths. If no shape is specified, the command will attempt to auto-detect the type based on the provided points.

Examples

```
prompt> gui_set_region {{-1743.945 18.357} {42.833 1523.657}}
1
```

See Also

- gui_get_region

---

gui_set_select_menu_adds_to_selection

Controls the setting of the Select > Add to Selection menu item specifies whether Select > Related Object in the GUI replaces or adds to the current selection.

Syntax

```
status gui_set_select_menu_adds_to_selection
-value true | false
```

Feedback

Arguments

`-value true | false`

Specifies whether Select > Related Objects in the GUI replaces or adds to the current selection. Specify *-value true* to append to the current selection, *-value false* to replace the selection.

Description

This command controls the setting of the Select > Add to Selection menu item specifies whether Select > Related Object in the GUI replaces or adds to the current selection.

This command is logged when the Select > Add to Selection menu item is invoked.

Examples

The following example enables adding to the current selection.

```
prompt> gui_set_select_menu_adds_to_selection true
```

---

gui_set_select_related_push_selection

Enable or disable select related pushes current selection

Syntax

`string` **`gui_set_select_related_push_selection`** `-value` *`boolean`*

Data Types

`boolean` `boolean`

Arguments

`-value` *`boolean`*

Boolean flag

Description

The *gui_set_select_related_push_selection* command enable or disable select related pushes current selection. It is intended for interactive usage in the GUI for the application.

Examples

Enable select related pushes current selection

```
prompt> gui_set_select_related_push_selection -value true
```

Feedback

gui_set_selected_errors

Changes the selection in the Error Browser to add or replace errors.

Syntax

int *gui_set_selected_errors*

```
-add | -replace errors
[-force]
```

Data Types

```
errors  string
```

Arguments

`-add errors`

Adds the specified errors to the current selection. This option is mutually exclusive with the *-replace* option.

`-replace errors`

Replaces the specified errors in the current selection. This options is mutually exclusive with the *-add* option.

`-force`

Forces the completion of the command even if it may cause performance degradation. This option is generally not recommended unless necessary, as it may lead to slower performance in the Error Browser.

Description

Sets new selected errors or adds new selected errors in the Error Browser. Errors are identified as a collection of error objects. If the *-add* option is given, the command adds the given errors to the currently selected errors. If the *-replace* option is given, the command replaces the current selection with the given errors. The command fails if the given errors are not in the current set specified by the *gui_set_current_errors* command, or with a click in the Error Browser tree view. The command returns 1 if successful, 0 otherwise.

See Also

- gui_clear_selected_errors
- gui_error_browser
- gui_set_current_errors

Feedback

gui_set_setting

Sets a setting on the specified window.

Syntax

gui_set_setting

```
-window WindowID
-setting Setting
-value Value

WindowID        String
Setting        String
Value        String | Bool | Int | Double
```

Arguments

`-window` *WindowID*

WindowID specifies the window to set the setting

`-setting` *Setting*

Setting specifies the setting to set

`-value` *Value*

Value specifies the value of the setting

Description

Sets a setting on the specified window. Windows are views or top level windows. The setting is a property of the window and the value's type is specific to the given setting.

Examples

```
shell> gui_set_setting -window Layout.1 -setting showCell -value true

shell> gui_set_setting -window Layout.1 -setting viewLevel -value 1
```

See Also

- gui_get_setting

gui_set_task_list

Set the list of tasks that are visible in the task assistant, and set their order.

Syntax

gui_set_task_list

Feedback

```
-tasks    TaskList

TaskList    List
```

Arguments

`-tasks TaskList`

TaskList specifies the list of tasks that will be visible in the task assistant and their order. Tasks which are not included in the list will still exist but will not be shown in the selection combo box of the task assistant.

Description

The gui_set_task_list command sets the list of tasks that are visible and available in the task assistant and sets their order.

Examples

The following simple example sets the visible list of tasks to "Design Planning" followed by "Routing".

```
gui_set_task_list -tasks {{Design Planning} {Routing}}
```

See Also

- gui_get_task_list
- gui_create_task

---

gui_set_utable

Set various state about User Tables.

Syntax

string *gui_set_utable*

```
[-name          Table_Name]
[-parent        Table_Name]

[-tag           Report_Tag]
[-title         Report_Title]
[-comment       Report_Comment]
[-menu          Root_Menu]

[-prefix        Prefix_Char [-column Column_Name] ]

[-action        TCL_Expr  -column Column_Name  -link Link_Text]

[-create_hook   TCL_Proc]
[-close_hook    TCL_Proc]
```

Feedback

```
[-enter_hook    TCL_Proc]
[-exit_hook     TCL_Proc]

[-select_hook   TCL_Proc]
[-sel_action    TCL_Proc]
[-dsel_action   TCL_Proc]

[-window        Window_name]
[-filter        Filter_Expr]

Table_Name          String
Report_Title        String
Report_Comment      String
Report_Tag          String
Root_Menu           String
TCL_Proc            TCL procedure call
Column_Name         String
Link_Text           String
Prefix_Char         Chars(afpnumkMGTPE), "A" for Auto, " " for none.
Window_Name         String
Filter_Expr         String
```

Arguments

`-name` *Table_Name*

A table name argument used with other arguments below.

`-parent` *Table_Name*

Set the parent table name for the given table name argument.

`-tag` *Report_Tag*

Set a tag string for the given table name argument.

`-title` *Report_Title*

Set a report title for the given table name argument.

`-comment` *Report_Comment*

Set a report comment for the given table name argument.

`-menu` *Root_Menu*

Assign a TCL defined Context Sensitive Menu Root name to this table that is shown when the user right clicks on any table cell in the table.

`-column` *Column_Name*

The column name argument is used with other arguments below.

Feedback

`-prefix` *`Prefix_Char`*

Formats numeric data to the given prefix char. Special prefix characters are " " space which means no formating and "A" which means automatic formating. If given a table name, then it only applies to that table. If also given a column name, then it only applies to that tables column. If given by itself then it sets the default for all table columns that are numeric. Examples: (...,n=nano,m=milli,k=killo,M=Mega...)

`-link` *`Link_String`*

The link string use with the *-action* option below.

`-action` *`TCL_Expr`*

These options allow you to define a link action for every empty table cell in a given column. A link action is basically a TCL procedure call. In addition you can pass arguments that reference other values in the same row but in different columns. This option required the use of the options *-column* which indicates the column that this action is applied to and the *-link* text that is shown in the table cell under that column. (See Example Below)

`-create_hook` *`TCL_Proc`*

Set table create TCL hook proc name. The proc is called when a new UserTable is created.

`-close_hook` *`TCL_Proc`*

Set table close TCL hook proc name. The proc is called when a UserTable is closed.

`-enter_hook` *`TCL_Proc`*

Set a specific table name enter hook TCL proc name. The named proc is called when a UserTable with the specified *-name* option is entered/shown. The argument to the proc is the name of the table that was entered/shown. Note: The enter hook is only run if the table is changed for the current UserTable window.

`-exit_hook` *`TCL_Proc`*

Set a specific table name exit hook TCL proc name. The named proc is called when a UserTable with the specified *-name* option is exited to show another table. The argument to the proc is the name of the table that was exited. Note: The exit hook is only run if the table is changed for the current UserTable window.

`-select_hook` *`TCL_Proc`*

Set table data select TCL hook proc name. This proc is called when any Table cell in any column is sected.

Feedback

`-sel_action` *`TCL_Proc`*

Set the TCL action proc name that is called when a selection is made in the *-column* option given above. The arguments to the proc are the data of the selection and the selected row number and the total number of rows selected.

`-dsel_action` *`TCL_Proc`*

Set the TCL action proc name that is called when a deselection is made in the *-column* option given above. The arguments to the proc are the data of the deselection and the deselected row number and the column name of the new selection. An empty new column argument means a selection in the same column was made.

`-window` *`Window_Name`*

This option is used with other options below.

`-filter` *`Filter_Expr`*

This allows you to set the filter value on the current table visible in the view given by the '-window' option.

Description

This command allows you to set various state and actions on User Tables.

Examples

The following example creates a new table MyTable and assigns the various state
and action options described above.

```
        # Create MyTable with columns: cell, voltage, current and add
 some data
# Note: the last column "Show" is left empty for an action column.
gui_create_utable -name MyTable \\
  -columns {cell voltage:double current:double Show}
gui_append_utable -name MyTable -rows {
  {A 5.0 0.2 {}}
  {B 6.0 0.4 {}}
  {C 7.0 0.6 {}}
}

# Create a context menu with one item:
set menuRoot "My Custom Menu"
gui_create_menu -root $menuRoot -menu "MyItem" -tcl_cmd "echo MyItem"

# Create various hooks that are executed at create/close and selection.
proc createTableHook { table } {
  puts stdout "*New table created: $table"
}
```

Feedback

```
proc closeTableHook { table } {
  puts stdout "*Closing table: $table"
}
proc selectHook { table } {
  set win [gui_get_current_window -mru -type UserTable]
  set columns [gui_get_utable -window $win -columns]
  set values  [gui_get_utable -window $win -values $columns]
  foreach v $values {
    echo "Table: $table, Selected Value: $v"
  }
  # return "1" if default selection action should be ignored
  return "0"
}
proc selAction {data row rowCount} {
  puts stdout "selAction $data $row $rowCount"
}
proc dselAction {data row newColumn} {
  puts stdout "dselAction $data $row $newColumn"

---

gui_set_utable_meta

Create a MetaData Object for use in creating a new UserTable.

Syntax

string *gui_set_utable_meta*

```
-name         MetaDataObj_Name
[-remove]
[-title       Report_Title]
[-comment     Report_Comment]
[-tag         Report_Tag]
[-menu        Root_Menu]
[-col_name    Column_Name]
[-col_type    Column_Type]
[-read_only]
[-hidden]
[-user_enums Column_Type_Enums]
[-user_list  Column_Type_List]

MetaDataObj_Name   String
Report_Title       String
Report_Comment     String
Report_Tag         String
Root_Menu          String
Column_Name        String
Column_Type        String
Column_Type_Enums  List of Strings
Column_Type_List   List of Strings
```

Feedback

Arguments

`-name` *`MetaDataObj_Name`*

The name of the MetaData object.

`-remove`

Remove and free the given MetaData object.

`-title` *`Report_Title`*

Report title for a table.

`-comment` *`Report_Comment`*

Report comment for a table.

`-tag` *`Report_Tag`*

A tag string assigned to the table.

`-menu` *`Root_Menu`*

User Context Sensitive Menu Root name.

`-col_name` *`Column_Name`*

A column name that has the following column type.

`-col_type` *`Column_Type`*

A column type name.

`-read_only`

Mark the given column name as read only which prevents editing data in that column.

`-hidden`

Mark the given column name as hidden.

`-user_enums` *`Column_Type_Enums`*

A list of single string values for a new user type defined by the -col_type argument.

`-user_list` *`Column_Type_List`*

A list of multi string values for a new user type defined by the -col_type argument. A table cell of this type can contain multiple unique values of this type separated by a comma.

Description

```
This command creates a new MetaData object that then can be used to add
 useful meta data to
```

Feedback

the creation of a new UserTable. A new UserTable is created via the gui_create_utable
and the gui_import_utable commands. MetaData can be used to define certain column data/object
types instead of using column name postfixes. Users can also define new data types that
are made of a list of unique string values. A table cell can then be set to only allow
single values (enums) of that new type or a comma separated list of values (lists) of that
new data type. MetaData can also be exported via the gui_export_utable command along with
the table data.

Examples

The following example creates a new MetaData object named myMetaObj which contains a
report title and comment.

```
shell> gui_set_utable_meta -name myMetaObj -title "My Report" -comment
 "This is a comment"
```

The following example adds a definition of a new data type 'myData' assigned to
the column 'myDataColumn'. This new data type has 4 values (valA valB valC and valD).
Also optionally the user can add a help string after the value separated by a
colon ':' which is used to show tool tips.

```
shell> gui_set_utable_meta -name myMetaObj -col_name myDataColumn
 -col_type myData -user_enums {
  {valA: Help string for valA...}
  {valB: Help string for valB...}
  {valC: Help string for valC...}
  {valD: Help string for valD...}
}
```

The following example then imports a CSV file and adds the previously defined MetaData to
that new table.

```
shell> gui_import_utable -file myTable.csv -meta_obj myMetaObj
```

---

gui_set_utable_values

Set the given UserTable values in the given column(s) and the filtered set of rows.

Syntax

string *gui_set_utable_values*

```
-name             Table_Name
-columns          Column_List
-values           Value_List
[-filter          Filter_Expr]

Table_Name       String
Column_List      StringList
Value_List       StringList
Filter_Expr      String
```

Arguments

`-name Table_Name`

The table name on which to set the new values.

`-columns Column_List`

Provides a list of one or more column names that indicate the location of values to set.

`-values Value_List`

Provides a list of values used to set in the columns given above. *Note:* The number of values must match the number of columns.

`-filter Filter_Expr`

To only update a certain set of rows in the table with new values you must ether first filter the table in the view or use this filter expression to only target the rows of interest.

Description

```
This command allows you to update/change the values in the table rows
selected by the given columns and the given filter value.
If no filter option is given the all rows will be updated unless the
table is currently viewed, then all rows will be updated that match
the current view filter setting.
```

Feedback

Examples

```
The following example updates the value of column 'direction' to 'out'
and the column 'state' to the value 'open' for all the rows that match
the filter where 'pin_module' is equal to 'my_module'.

shell> gui_set_utable_values -name $table -column {{direction} {state}}
 -value {out open} \\
     -filter {pin_module == my_module}
```

---

gui_set_vm

Sets visual mode attributes.

Syntax

string *gui_set_vm*

```
-name identifier
[-update_cmd update_command]
[-title label]
[-help_topic subject]
[-infotip infotip]
[-buckets buckets]
[-icon string]
[-netfilter string]
[-float bool]
[-set_exaggerations]
[-top_exaggeration float]
[-mid_exaggeration float]
[-bot_exaggeration float]
[-show_only_pins_of_nets bool]
[-enable_bucket_delete bool]
```

Data Types

```
identifier          string
update_command      string
label               string
subject            string
infotip             string
buckets             string
net_filter          string
icon_spec           string
```

Feedback

Arguments

`-name` *identifier*

Specifies the name of the visual mode to be modified. This name is used as the argument when the associated visual mode commands requires a visual mode name to be specified.

`-update_cmd` *update_command*

Specifies an optional Tcl command that is executed when the visual mode is accessed. A typical use for this command is to update the state of the visual mode if its contents are likely to change under certain circumstances.

`-title` *label*

Specifies an optional title. The title can include embedded spaces. Use this option to provide a label for the visual mode in the GUI.

If you do not specify the *-title* option, the default title is an empty string and the tool uses the *-name* option value to provide the label.

`-help_topic` *subject*

Specifies the help topic text string. This text is used as the subdirectory to find a help page related to the visual mode.

`-infotip` *infotip*

Specifies the infoTip string.

`-buckets` *buckets*

Specifies the rendering order of the buckets. The tool renders the specified buckets from left to right based on their order in the list. Buckets that are not included in the list are rendered before any of the buckets that are specified in the list.

`-icon` *string*

Specifies the icon file name. Use this option to provide an icon for GUI menus.

`-netfilter` *string*

Specifies the net connection filtering.

`-float true | false`

Specifies whether the bucket contents have a floating point range. By default, the value is false.

`-set_exaggerations`

Specifies the bucket exaggerations.

Feedback

`-top_exaggeration` *float*

Specifies the exaggeration for the top bucket, the value should be greater than or equal to zero. By default, the value is 0.

`-mid_exaggeration` *float*

Specifies the exaggeration for the middle bucket, the value should be greater than or equal to -1. By default, the value is -1.

`-bot_exaggeration` *float*

Specifies the exaggeration for the bottom bucket, the value should be greater than or equal to zero. By default, the value is 0.

`-show_only_pins_of_nets true | false`

Indicates that layout only show pins of net objects in buckets.

`-enable_bucket_delete true | false`

Specifies whether the buckets can be deleted from context menu. Only discrete visual mode buckets can be deleted. By default, the value is false.

Description

The *gui_set_vm* command modifies one or more attribute values of an existing visual mode.

Examples

The following example changes the title of a visual mode from "mycoloring1" to "test":

```
prompt> gui_set_vm -name mycoloring1 -title {test}
```

See Also

- gui_create_vm
- gui_create_vmbucket

- gui_remove_vmbucket
- gui_set_vmbucket
- gui_update_vm

Feedback

gui_set_vmbucket

Set attributes for Visual Mode Bucket

Syntax

string *gui_set_vmbucket* -vmname *mode_identifier*

-name *bucket_identifier* [-infotip *infotip*] [-netfilter *net_filter*] [-color *color*] [-pattern *pattern*] [-exaggeration double] [-number int] [-maxval double] [-minval double] [-visible *visibility*] [-title *label*] [-collection *handle*] [-above *bucket_identifier* | -below *bucket_identifier* | -at *top*| *bottom*]

```
string  mode_identifier
string  bucket_identifier
string  infotip
string net_filter
string  color
string  pattern
string  visibility
string  label
string  handle
string  bucket_identifier
string  bucket_identifier
string  top|bottom
```

Arguments

`-vmname mode_identifier`

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes use the gui_list_vm command.

`-name bucket_identifier`

Specifies the name of the visual mode bucket to be modified. To see the list of buckets associated with a specific visual mode use the gui_get_vm command with the -buckets option.

`-infotip infotip`

String for infotip.

`-netfilter net_filter`

Specifies net connection filtering.

`-color color`

Specifies bucket rendering color. Supports color naming by RGB triplet (for example: "#FFFF00" for yellow) as well as standard names (for example: "yellow").

Feedback

`-pattern` *pattern*

Specifies bucket rendering fill pattern. Supported patterns are: SolidPattern, HorPattern, VerPattern, CrossPattern, BDiagPattern, FDiagPattern, DiagCrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, NoBrush.

`-exaggeration double`

Specifies bucket min pixel exaggeration value >= 0.

`-number int`

Specifies bucket display number value >= 0 that is used to provide a display number for the visual mode bucket in the gui. If the -number option is not specified, it will default to the number of objects in the bucket.

`-maxval double`

Specifies bucket maximum value.

`-minval double`

Specifies bucket minimum value.

`-visible` *visibility*

Specifies visibility state of bucket contents. Valid values are TRUE and FALSE.

`-title` *label*

Specifies an optional string (that can include embedded spaces) that is used to provide a label for the visual mode bucket in the gui. If the -title option is not specified, it will default to an empty string and the -name argument value value will be used to provide the labeling instead.

`-collection` *handle*

Tcl object collection to be colored by this visual mode bucket.

`-above` *bucket_identifier*

Specifies an optional visual mode bucket name above which the current bucket is to be rendered.

`-below` *bucket_identifier*

Specifies an optional visual mode bucket name below which the current bucket is to be rendered.

`-at` *top|bottom*

Specifies an optional string indicating whether the current visual mode bucket is to be rendered at the top or bottom of all other buckets. Valid values are top and bottom.

Feedback

Description

The gui_set_vmbucket command modifies an instance of a visual mode bucket.

Examples

Change the color and pattern for the bucket named "cat1" in the visual mode "foo":

shell> *gui_set_vmbucket -vmname foo -name cat1 -color #00FF00 -pattern FDiagPattern*

Color the objects in the current selection red by placing them in the bucket named "cat1" in the visual mode "foo" and setting its bucket color:

shell> *gui_set_vmbucket -vmname foo -name cat1 -collection [get_selection] -color red*

---

gui_set_window_pref_key

Create a preference key owned by a particular window or window type

Syntax

```
new_value gui_set_window_pref_key
{ -window window_id | -window_type window_type }
[ -category category ]
-key key
-value_type value_type
-value value
```

Data Types

```
window_id       string
window_type     string
```

Feedback

```
category        string
key             string
value_type      string
value           string
```

Arguments

`-window` *window_id*

Specifies the name of the window that the preference will be applied to. This option is mutually exclusive with the -window_type option.

`-window_type` *window_type*

Specifies the name of the window type that instances of the type will have the preference be applied to. This option is mutually exclusive with the -window option.

`-category` *category*

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

`-key` *key*

Specifies the name of the key to create.

`-value_type` *value_type*

Specifies the the data type of the value of the key. It must be one of [bool | integer | double | color | string].

`-value` *value*

Specifies the value of the key. The value should be set appropriately in accordance with its value type. The bool type accepts [true, false, 0, 1, on, off]. The color type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

Returns

new_value

The new value of the key.

Description

This command creates a preference key with the specified key name or sets the value of an existing pref key. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to a default category. Returns the value of the preference key.

Feedback

Examples

The following example will create a window and set a preference on that window.

```
shell> set wnd [gui_create_window -type Console]
shell> gui_set_window_pref_key -window $wnd -category {caption} -key
 {title}
 -value_type string -value {Command Console}
```

---

gui_set_window_preset

Sets the specified preset for object specified by window_type

Syntax

```
status gui_set_window_preset
-window_type window_type
[-system]
[-shared]
-default
-preset preset
```

Feedback

Data Types

```
window_type     string
preset          string
```

Arguments

`-window_type` *window_type*

Specifies the name of the window type that the presets be applied to.

`-system`

Apply given system preset. This option is mutually exclusive with the -shared, -default option.

`-shared`

Apply given shared preset. This option is mutually exclusive with the -system, -default option.

`-default`

Apply preference setting. This option is mutually exclusive with the -system, -shared, preset option.

`-preset` *preset*

Specifies the preset to be applied. This option is mutually exclusive with the -default option.

Description

This command applies the default or specified preset to a window type. This command has been deprecated, please use gui_set_preset instead.

Examples

The following example applies the system presets 'floorplan' to the Layout.

```
prompt> gui_set_window_preset -window_type Layout -preset floorplan
 -system
```

See Also

- gui_set_preset
- gui_get_presets
- gui_get_window_presets

Feedback

gui_show_command_form

Generate and show a form dialog for a shell command.

Syntax

string *gui_show_command_form* -command *command*

```
string command
```

Arguments

```
-command command
```

The name of the shell command to show in the form.

Description

Create a form dialog for a shell command. The form contains fields to allow entry of option arguments.

The dialog provides the following operations for the command:

```
- execute the command
- append the command to a script
- show the man page for the command.
```

This command creates form dialogs for application defined commands. It will also create a form dialog for a public user defined tcl proc when its option value types have been defined using the *define_proc_attributes* command. The kinds of value input fields used in the form depends on the *type_name* attribute given for the option using the *-define_args* option. See man pages for *define_proc_attributes* and *gui_report_proc_arg_type_names* for more information.

This command is available only when the GUI is running.

Examples

The following example creates a form dialog for the command *gui_start*

```
shell> gui_show_command_form -command gui_start
1
```

The following is an example of a tcl proc definition followed by a *define_proc_attribute* command invocation to define its attributes. The proc is then shown in a form dialog with the *gui_show_command_form* command. The example proc accepts a net and routing layers as arguments.

```
shell> proc myProc {args} {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo $argname = $results($argname)
```

Feedback

```
  }
}
shell> define_proc_attributes myProc \\
  -info "echo argument values" \\
  -define_args { \\
    {-net "select a net" "net" string \\
          {required {type_name net}}} \\
    {-layers "select routing layers" "routing layers" list \\
          {optional {type_name {layer {subtype routing}}}}} \\
  }
shell> gui_show_command_form -command myProc
```

See Also

- define_proc_attributes
- gui_report_proc_arg_type_names
- gui_start
- gui_stop

---

gui_show_connectivity

Generate user table and chart to present the connection data among muti-dies for 3DIC designs.

Syntax

```
status gui_show_connectivity
```

Arguments

This command has no arguments.

Description

This command collects information and builds the inter-connectivity table and chart for multi dies, which includes die connectivity and bump statistics among multi dies/blocks and draw force-directed graph.

Examples

The following example generates user table and force-directed chart in 3DIC designs.

```
prompt> gui_show_connectivity
```

---

gui_show_file_in_editor

Show the contents of a file in an external text editor.

Feedback

Syntax

```
gui_show_file_in_editor
-filename filename
[ -line linenum ]
```

Data Types

```
filename string
linenum  integer
```

Arguments

`-filename filename`

filename specifies the name of the file to be edited.

`-line linenum`

linenum specifies the line in the file to start editing at.

Description

The gui_show_file_in_editor command opens a text editor to edit the specified file. The editor is a separate task so doen not block the current application.

By default the file is edited using the text editor from the EDITOR environment variable in a xterm. If the EDITOR environment variable is not set then the 'vi' text editor is used.

Both the editor and terminal (xterm) are searched for on the users path. If either the editor or terminal can no be found the command will fail.

Examples

The following example shows the file "test.txt" starting at line 100.

```
shell> gui_show_file_in_editor -file test.txt -line 100
```

See Also

- gui_show_url_in_browser

---

gui_show_man_page

Show a man page in the man browser

Syntax

string *gui_show_man_page* [-apropos]

[*topic*]

```
string topic
```

Feedback

Arguments

topic

Man page topic to be shown.

-apropos

Use the apropos command so search for commands that are related to the given topic.

Description

This command will launch or raise the man page browser, and display the topic specified in it. If no topic is specified, then the HOME page for man page indexes will be shown.

If the specified topic does not exactly match a given man page, then additional searching will be done for commands. If the topic matches one or more commands, then an index page will be generated showing all of the commands which match the specified topic pattern. If the topic doesn't match any commands, then we will use the topic as the initial part of a command and add a * to it and do command matching. Any completions for the command will be shown on an index page that can then be used to select a man page for viewing.

If the -apropos option is specified, then the topic will be searched via the apropos command and the topics returned will be shown with thier brief help strings, and provide links the the man pages referenced.

Examples

To show the man page for the find command:

gui_show_man_page find

To show the man page for all commands containing the word cell:

gui_show_man_page *cell*

To show the man page for the get_attribute command using command completion:

gui_show_man_page get_attr

See Also

- man
- apropos

---

gui_show_map

Displays or hides the specified visual mode or map mode.

Feedback

Syntax

```
string gui_show_map
-map map_name
-show true | false
[-window window]
```

Data Types

```
map_name        string
window          string
```

Arguments

`-map map_name`

Specifies the name of the visual mode or map mode.

`-show true | false`

Displays the visual mode or map mode when set to *true*, or hides the visual mode or map mode when set to *false*.

`-window window`

Specifies the name of layout window in which to display or hide the visual mode or map mode.

Description

This command displays or hides the specified visual mode or map mode. If the *-window* option is not specified, the command uses the most recently active layout window.

Examples

The following example displays the highlight visual mode in the most recently active layout window:

```
prompt> gui_show_map -map Highlight \\
        -show true
```

See Also

- gui_get_map_list

---

gui_show_palette

Shows the palette in the specified window state.

Syntax

```
status gui_show_palette
{ -name palette_id | -type palette_type }
```

Feedback

```
[ -parent parent_name ]
[ -show_state window_state ]
[ -dock_edge dock_edge ]
[ -size {width height} ]
[ -ind  index ]
```

Data Types

```
palette_id    string
palette_type  string
parent_name   string
window_state  string
dock_edge     string
width         float
height        float
index         integer
```

Arguments

`-name palette_id`

Specifies the palette name id or title.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this name in all toplevel windows are shown.

This option precludes the *-type* option

`-type palette_type`

Specifies the palette type id. Any matching palette of this type will be shown.

If the *-parent* option is specified only palettes in the specified parent toplevel window are shown. If the *-parent* option is not specified all palettes of this type in all toplevel windows are shown.

This option precludes the *-name* option

`-parent parent_name`

Specifies the parent toplevel window name.

`-show_state window_state`

Specifies the window state to show the palette.

Legal states are *maximized*, *minimized*, *normal*, or *docked*.

The default is *normal*.

`-dock_edge dock_edge`

Specifies the edge to dock the palette.

Feedback

Legal dock edges are *left*, *top*, *right*, or *bottom*.

Note: this option is only valid if the state is set to *docked*.

The default is *right*.

`-size {width height}`

Specifies the width and height of the palette.

Note: this option is only valid if the state is set to *normal*.

`-ind index`

Specifies the index of the palette to show.

Description

This command shows the specified palette in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

Examples

The following example shows the Layer palette docked on the left of the workspace.

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_palette -type Layout -parent $top]
shell> gui_show_palette -name $layout -show_state docked -dock_edge left
```

See Also

- gui_hide_palette

---

gui_show_rtl_source_file_line

Show the contents of an RTL file in the RTL Source Browser view.

Syntax

```
status gui_show_rtl_source_file_line
[ -window string ]
-filename string
[ -line int ]
```

Arguments

`-window string`

Window specifies the GUI window to show the view in.

This option is optional, the current window is used by default.

Feedback

`-filename` *string*

Filename specifies the name of the file to be show.

`-line` *int*

Line specifies the line in the file to move to.

This option is optional, the first line of the file is used by default.

Description

The gui_show_rtl_source_file_line command shows the contents of the specified RTL file in a RTL Source Browser view. A line can also be specified to automatically move to that line in the file.

If the format of the file is recognised then syntax highlighting will be added and folding of blocks allowed.

Currently Verilog, System Verilog and VHDL files are supported and are recognised by their file suffix (.v, .sv/.vs, .vhd/.vhdl).

Examples

The following example shows the file "test.v" starting at line 100.

```
shell> gui_show_rtl_source_file_line -filename test.v -line 100
```

See Also

- gui_create_window

---

gui_show_source_file

Show the contents of a file in the source browser view.

Syntax

```
status gui_show_source_file
[ -window string ]
-filename string
[ -line int ]
[ -show_markers ]
```

Arguments

`-window` *string*

Window specifies the GUI window to show the view in.

This option is optional, the current window is used by default.

Feedback

`-filename` *string*

Filename specifies the name of the file to be show.

`-line` *int*

Line specifies the line in the file to move to.

`-show_markers`

Specifies whether to show the markers list in the source browser view.

Description

The gui_show_source_file command shows the contents of the specified file in a source browser view. A line can also be specified to automatically move to that line in the file.

If the format of the file is recognised then syntax highlighting will be added and folding of blocks allowed.

Currently only tcl, Verilog and VHDL files are supported and are recognised by their file suffix (.tcl, .v, .vhd/.vhdl).

Examples

The following example shows the file "test.tcl" starting at line 100.

```
shell> gui_show_source_file -filename test.txt -line 100
```

See Also

- gui_show_file_in_editor
- gui_show_url_in_browser

---

gui_show_task_assistant

Show the task assistant.

Syntax

gui_show_task_assistant

```
-task          TaskName
-item          ItemName

TaskName         String
ItemName         String
```

Feedback

Arguments

`-task` *`TaskName`*

TaskName specifies the name of the task to show in the task assistant.

`-item` *`ItemName`*

ItemName specifies the name of the task item to show in the task assistant.

Description

The gui_show_task_assistant command opens the task assistant window and displays the page for given task and task item.

See Also

- gui_create_task
- gui_set_current_task
- gui_get_current_task_item
- gui_get_current_task_page

---

gui_show_timing_paths

Shows the details of a collection of timing paths in a timing path inspector.

Syntax

gui_show_timing_paths

```
-paths paths
[-new]
```

Arguments

`-paths`

Collection of timing pathss to be inspected.

`-new`

Creates a new timing path inspector window.

Description

The command shows the details of a collection of timing paths in a timing path inspector. Unless requested by the user, this command will use the most recently used timing path inspector window if it exists. Otherwise it will create a new timing path inspector window.

Feedback

Examples

The following example inspects a collection of timing paths.

```
prompt> gui_show_timing_paths -paths $paths
```

See Also

- change_selection

---

gui_show_toolbar

Displays the specified toolbar or all the toolbars in the specified window or for a window type.

Syntax

void *gui_show_toolbar*

```
-toolbar tool_bar_name | -all
[-window window_id]
[-window_type window_type]
```

Data Types

```
tool_bar_name      string
window_id          string
window_type        string list
```

Arguments

`-toolbar tool_bar_name`

Specifies the toolbar you want to display. The *-toolbar* option and the *-all* option are mutually exclusive.

`-all`

Displays all the toolbars in the specified window. The *-all* option and the *-toolbar* option are mutually exclusive.

`-window window_id`

Specifies the window in which you want to display the specified toolbar or all toolbars. This option is mutually exclusive with the *-window_type* option. If both *-window* and *-window_type* options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

`-window_type window_type`

Specifies the window types in which you want to display the specified toolbar or all toolbars. All existing windows of the given types will be affected. Toolbar

Feedback

visibility may be set on a window type before a window of the type exists. This option is mutually exclusive with the *-window* option. If both *-window* and *-window_type* options are omitted, then by default the tool displays the toolbar or toolbars in the active window.

Description

This command displays either all the toolbars or the toolbar with the specified name in the window with the specified window ID, or in all windows of the given window type.

Toolbar visibility set by this command will override any visibility setting that has been saved and restored from previous sessions. The last toolbar visibility set by this command or by *gui_hide_toolbar* will be saved and restored on next invocation of the tool if save and restore has not been disabled.

Examples

The following example displays the File toolbar in the active window:

```
prompt> gui_show_toolbar -toolbar File
```

The following example displays all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_show_toolbar -all -window LayoutWindow.1
```

The following example displays the File toolbar in all TimingWindow type windows:

```
prompt> gui_show_toolbar -all -window_type TimingWindow
```

The following example display all the toolbars in all window types:

```
prompt> gui_show_toolbar -all -window_type [gui_get_window_types -type
 toplevel]
```

See Also

- gui_create_toolbar
- gui_delete_toolbar
- gui_create_toolbar_item
- gui_delete_toolbar_item
- gui_hide_toolbar
- gui_get_toolbar_names
- gui_get_window_types

Feedback

gui_show_url_in_browser

Show the contents of a URL in an external web browser.

Syntax

gui_show_url_in_browser

```
-url URL

URL String
```

Arguments

`-url` *Url*

Url specifies the url to be displayed.

Description

The gui_show_url_in_browser command an external web browser to display the specified web page. The default web browser is defined by the application but is usually 'firefox' on UNIX platforms.

If the web browser supports external comminication (which 'firefox' does) then if no web browser is running the web browser is started. If the web browser is running then the URL is loaded in the browser usually as a new tab.

The default browser can be set using the 'gui_online_browser' variable but the set of valid browsers is usually restricted by the application so not all browsers may be supported. If a unsupported browser is specified the command will fail.

See Also

- gui_online_browser
- gui_show_file_in_editor

gui_show_utable

Show the current loaded user tables in a UserTable view.

Syntax

string *gui_show_utable*

```
[-name            Table_Name]
[-window          Window_Name]
[-filter          Filter_Expr]

[-distribution]   [-columns Column_List]
```

Feedback

```
[-report]          [-columns Column]
[-compress]        [-columns Column]

[-plot             Plot_Type]        [-columns Column]

[-import           CSV_Filename      [-tsv_mode] [-ssv_mode] [-report_type]]
[-meta_obj         MetaObj_Name]
[-open             utable_Filename   [-read_only]]

[-mru]
[-top_window]

Table_Name       String
Filter_Expr      String
Column           String
Column_List      StringList
View_Name        String
CSV_Filename     String
MetaObj_Name     String
utable_Filename  String
Plot_Type        box|distribution|scatter
```

Arguments

`-name Table_Name`

The name of the user table to show inside the view. If not given, the view will show the default help page. The user can then select a table via the table selector located at the top of the view.

`-window Window_Name`

The name of an existing UserTable window/view to activate.

`-filter Filter_Expr`

Apply the given filter expression to the opened table view. *Note:* This option is exclusive with the *-import* option. To use this command and filter option you must first use *gui_import_utable*.

`-distribution`

Show table in distribution mode for the column given by the '-columns' option.

`-report`

Show table in report mode for the list of columns given by the '-columns' option.

`-compress`

Show table with column given by '-columns' option, compressed by common bus notations. *Note:* If given a list of columns only the first column is used to compress bus names. Additional columns are given a postfix to indicate the reduction function used on those numeric columns, by default the function

Feedback

is 'MAX', other allowed functions are 'MIN', 'SUM' and 'MEAN'. See example below.

`-plot` *`Plot_Type`*

Show a plot of the table data for the columns given by the '-columns' option.

`-columns` *`Column_List`*

Provides a list of one or more column names for the previous options.

`-import` *`CSV_Filename`*

The name of a CSV (comma seperated values) file to import and create a UserTable from. A column configuration form is presented to allow the user to adjust the final produced UserTable.

`-tsv_mode`

This flag changes the default delimiter from the comma char to the tab char.

`-ssv_mode`

This flag changes the default delimiter from the comma char to the semicolon char.

`-report_type`

This flag causes the reader to interpret the file as a report file and convert it into a user table. *Note:* Currently only the 'report_constraint -all_violators' report can be converted.

`-meta_obj` *`MetaObj_Name`*

Optional MetaData object name used to define table meta data. See the command gui_set_utable_meta for more information.

`-open` *`utable_Filename`*

The name of a UserTable native filename (.utable extension) to load into memory and present to the user. *Note*, this option is exclusive with the *-import* option.

`-read_only`

This flag can only be used with the *-open* option. It opens the file in a streaming read only manner, not copying all the data into memory which can save a lot of system memory if the file is huge.

`-mru`

This flag will show the given table in the most recently used User Table view (mru). This option can not be used with the *-window* option.

Feedback

`-top_window`

This flag will also open a new top level window to house the User Table view in.

Description

```
This command creates a new view (or reuse an existing view) to display
 and
interact with your User Tables. For convenience, options are given for
 you
to also import or open a new table from a file and display it.

User Tables provide a way for you to define and interact with your own
 tables of data.
The data can persist on disk separate from the design database, and is
 completely
under your control. User Tables can be generated from the attributes of a
 set of
selected objects or they can come from external sources via an ASCII
 value file
in CSV/TSV/SSV format.

Interactively these tables can be viewed and support sorting, filtering,
 summary reporting,
value distributions, editing, etc. as well as the ability to
 select/highlight objects in
the design using the object names in columns identified as object type
 columns.

This command is available only when the GUI is running.
```

Examples

The following example just creates and opens a new UserTable view.

```
shell> gui_show_utable

The following example opens a new UserTable view and displays the
 contents of my_table.

shell> gui_show_utable -name my_table

The following example opens a new UserTable view and shows the import
 form used to configure
the table being created from the values file results.csv. If no header
 line is supplied
in the values file the configuration form will use default names that can
 be edited by the
user before committing to table creation.

shell> gui_show_utable -import results.csv
```

Feedback

```
The following example opens a new UserTable view and connects to the
 UserTable file
my_table.utable in a read only streaming mode for display.

shell> gui_show_utable -open my_table.utable -read_only

The following example used the most recently used UserTable view and
 shows a compressed table
on the column {Cell Name} and assignes the 'SUM' reduction function on
 the given columns.

shell> gui_show_utable -name my_table -mru -columns { {Cell Name} {Int
 Power:SUM} {Tot Power:SUM} } -compress
```

---

gui_show_window

Show the window in the specified window state

Syntax

```
status gui_show_window
[ -window window_id ]
[ -show_state window_state ]
[ { -rect rect | -size isize } ]
```

Data Types

```
window_id       string
window_state    string
```

Feedback

```
rect            {{x1 y1} {x2 y2}}
isize           {width height}
```

Arguments

`-window` *window_id*

Specifies the toplevel window or view id to show. If not specified then the current active top-level window is used.

`-show_state` *show_window_state*

Specifies the window state to show the toplevel window or view.

For a toplevel window we have one of:

```
normal    - show at preferred size
maximized - show maximized (fill whole screen)
minimized - show iconized
hidden    - hide but do not destroy
```

Note: The window manager may or may not fully honor the specified state. See your window manager documentation for more details.

For a view window we have one of:

```
normal    - show at preferred size in view area and raise to top
maximized - show maximized in view area and raise to top
minimized - show iconized in view area
hidden    - hide but do not destroy
```

Note: If displaying maximized then any existing view windows are also maximized. If displaying minimized or normal then any maximized windows are shown as normal.

The default is *SHOW_WINDOW_STATE_NORMAL*.

`-rect` *rect*

Specifies the size and position of the window.

It is of this format "{{x1 y1} {x2 y2}}", where {x1 y1} specifies the top left location and {x2 y2} specifies the bottom right location of the window.

Note: This option precludes the use of the *-size* option.

`-size` *isize*

Specifies the width and height of the window.

It is of this format "{width height}"

Note: This option precludes the use of the *-rect* option.

Feedback

Description

This command shows the specified toplevel window or view in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

Examples

The following examples will create a layout window then use this command to illustrate the various options

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_window -type Layout -parent $top]
shell> gui_show_window -window $layout -show_state {maximized}
shell> gui_show_window -window $layout -show_state {normal}
shell> gui_show_window
```

- gui_get_window_types
- gui_get_window_ids
- gui_set_active_window
- gui_get_current_window

---

gui_show_window_toolbar

Show toolbar in view

Syntax

```
status gui_show_window_toolbar
-window window_id
[ -toolbar string ]
```

Data Types

```
window_id  string
```

Feedback

Arguments

`-window` *`window_id`*

Specifies the view name id.

Note: When in an intialization or control callback the window and toolbar will be defaulted to the current values so this option does not need to be specified.

`-toolbar` *`string`*

Specifies the optional toolbar name to show.

Note: the command will fail if the set does not exist

Description

This command shows the specified view's toolbar.

Note: a view's toolbar will only be shown if it has controls in it.

Examples

The following example will show a Charts View and show the toolbar.

```
shell> set top [gui_create_window -type TopLevel]
shell> set charts [gui_create_window -type Charts -parent $top]
shell> gui_show_window_toolbar -window $charts
```

See Also

- gui_create_window
- gui_hide_window_toolbar

---

gui_start

Starts the application GUI.

Syntax

```
status gui_start
[-file script]
[-no_windows]
[-offscreen 1|0]
[-- x_args ...]

string script
```

Feedback

Arguments

`-file` *script*

The given script file is sourced before the GUI starts.

`-no_windows`

The GUI starts without showing the default window.

`-offscreen`

If the specified value is 1 then the GUI starts in offscreen mode.

If the specified value is 0 then the GUI starts in normal (X Display) mode.

`--` *x_args*

X11-specific arguments to pass to the X connection.

Description

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. start_gui is an alias for gui_start.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful gui_start command has no effect.

Examples

The following example starts the application GUI.

shell> *gui_start*

See Also

- gui_stop
- start_gui
- stop_gui

---

gui_stop

Stops the application GUI.

Syntax

```
status gui_stop
 [-close]
```

Feedback

Arguments

`-close`

Close the GUI so it can be restarted on a different display.

Without this option (the default) the GUI is just disabled and hidden and can be quickly restored using gui_start.

The limitation of not using close is that the same display must be used when the GUI is started again.

Description

This command stops the application GUI and returns to the shell prompt.

It is ignored if the application GUI has not been started or has been stopped.

stop_gui is an alias for gui_stop.

Examples

The following example stops the application GUI and returns to the shell prompt.

shell> *gui_stop*

See Also

- gui_start
- start_gui
- stop_gui

---

gui_trim_dangling_wires

Trims dangling wire ends of selected wires or nets.

Syntax

status *gui_trim_dangling_wires*

`[object_list]`

Data Types

object_list collection

Feedback

Arguments

object_list

Specifies a collection or selection set containing objects to trim. If this option is not specified, the global selection set is used.

Description

This command trims dangling ends of selected net shapes, net shapes of selected nets, selected route corridor shapes, or route corridor shapes of selected route corridors.

Only net shapes and route corridor shapes with connections at both ends will be trimmed. Unconnected shapes or shapes only connected at a single point will be ignored. You can manually delete these shapes if required.

Trimming of dangling net shapes on power and ground nets is limited to selected net shapes. Net shapes of selected power and ground nets will be ignored. This option allows you to do some minor repairs but reduces the chance that you will accidently try to repair the whole power mesh which could be slow and is better achieved using separate power planning commands.

This command honors the 'is_fixed' attribute. Any fixed net shapes or route corridor shapes are ignored unless 'Ignore fixed attribute' is set in the Edit Options dialog.

Examples

The following example trims dangling ends for all net shapes on the net N1.

```
prompt> change_selection [get_nets N1]
prompt> gui_trim_dangling_wires
```

This example uses an alternative syntax with a collection.

```
prompt> gui_trim_dangling_wires [get_nets N1]
```

See Also

- change_selection
- get_edit_setting
- get_selection
- set_edit_setting

---

gui_update_attrgroup

Updates a group of attributes for an object type.

Feedback

Syntax

```
status gui_update_attrgroup
-class design_object
-name name
[-attr_list {{attr_1}...{attr_n}}]
[-add]
[-delete]
[-move up | down | top | bottom | after | before]
[-attr attribute]
[-anchor attribute]
```

Data Types

```
design_object       string
name                string
attr_1              string
attr_n              string
attribute           string
```

Arguments

`-class design_object`

Specifies the type of design object.

`-name name`

Specifies the non-editable name of the attribute group to update for the specified object type.

`-attr_list {{attr_1}...{attr_n}}`

Lists and orders the attributes to be included in the group.

`-add`

Adds the attribute specified by the *-attr* option to the end of attributes list, by default, or after the attribute specified by the *-anchor* option.

`-delete`

Removes the attributes specified by the *-attr* option from the attribute list. Note that the attribute still exists.

`-move up | down | top | bottom | after | before`

Moves the attribute specified by the *-attr* option in the specified direction. If you specify *before* or *after* to move the attribute relative to the position of a reference attribute, use the *-anchor* option to specify the reference attribute.

`-attr attribute`

Specifies the attribute to be added, removed, or moved with the *-add*, *-delete*, or *-move* option.

Feedback

`-anchor` *attribute*

Specifies the reference attribute to be used with the *-add* or *-move* option.

Description

The *gui_update_attrgroup* command updates an attribute group for the specified object type. You can reset the entire attribute list by using the *-attr_list* option, or you can change the list by adding, removing, or moving with a single attribute.

The order of the attributes in an attribute group is important and is set by the *-attr_list* option when you create or update the group.

Examples

```
prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -attr_list { "TestAttr1" "TestAttr2" "TestAttr3" }

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -add -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -add -attr "TestAttr5" -anchor "TestAttr2"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -delete -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \\
   -move down -attr "TestAttr2"
```

See Also

- gui_create_attrgroup
- gui_delete_attrgroup
- gui_list_attrgroups

---

gui_update_pref_file

Save current application preferences to the user preference file.

Syntax

string *gui_update_pref_file* [-file *FilePathName*]

`FilePathName` *String*

Feedback

Arguments

`-file` *`FilePathName`*

FilePathName specifies the full pathname of the user preference file to write the current preferences to. If this option is missing, the file to write to is controlled by the gui variables : pref_file_name and pref_file_path. These two variables are set with the gui_set_var command and their values retrieved with the gui_get_var command.

Description

This command updates the user preference file. Normally, application will automatically save user preferences to a default system preference file on exit, and retrieve the preferences from the default user preference file on application start. So, this command is rarely used, except internally.

---

gui_update_vm

Update Visual Mode

Syntax

string *gui_update_vm* -name *identifier*

`string` *`identifier`*

Feedback

Arguments

`-name identifier`

Specifies the visual mode name whose associated tcl update command will be executed. The tcl update command is associated with the visual mode using the -update_cmd option to the gui_create_vm or gui_set_vm commands.

Description

Execute a visual mode's associated tcl update command.

Examples

To force the visual mode "vm1" to execute its associated update command, use the following:

shell> *gui_update_vm -name vm1*

See Also

- gui_create_vm
- gui_create_vmbucket
- gui_get_vm
- gui_get_vmbucket
- gui_list_vm
- gui_remove_vm
- gui_remove_vmbucket
- gui_set_vmbucket
- gui_set_vm

---

gui_update_vm_annotations

Updates visual mode annotations.

Syntax

string *gui_update_vm_annotations*

-clear -center -add *points* -draw_net *style* [-type *shape*] [-text *message*] [-color *color*] [-pattern *pattern*] [-line_style *line_style*] [-width *width*] [-info_tip *info_tip*] [-query_text *query_text*] [-query_command *query_command*] *object*

Feedback

Data Types

points	list
style	string
shape	string
message	string
color	string
pattern	string
line_style	string
width	integer
info_tip	string
query_text	string
query_command	string
object	string

Arguments

`-clear`

Removes all annotations from the specified object.

`-center`

Interprets all object locations as the centers of the objects rather than their origins.

`-add` *points*

Adds points for the annotation shape that you specify with the *-type* option. The points are specified by a tool command language (Tcl) list in which each element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.

Feedback

- bbox_ul : the annotation is placed at the upper left of the

  bounding box of the object. • bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

`-draw_net` *`style`*

Specifies how the nets are displayed in the layout view for this annotation if the specified objects are nets or physical buses.

This annotation overrides the current net display setting on the View Settings panel. The valid *style* values are

`flyline`
`routing`
`routing_flyline`

`-type` *`shape`*

Specifies the type of annotation. The valid *shape* values are

`rect`
`line`
`arrow`
`polygon`
`polyline`
`text`

`-text` *`message`*

Specifies a text string that you want to display.

`-color` *`color`*

Specifies the color. The default is the bucket color.

`-pattern` *`pattern`*

Specifies the fill pattern. The default is none.

Feedback

`-line_style` *line_style>*

Specifies the line style. The default is none.

`-width` *width*

Specifies the line width. The default is 1.

`-info_tip` *info_tip*

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_text` *query_text*

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
%object  a collection containing the annotation
```

`-query_command` *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

```
%window  the layout window name
%view    the layout view name
```

Feedback

```
%object  a collection containing the annotation
%x       the x position clicked in design coordinates
%y       the y position clicked in design coordinates
```

object

Specifies the object with which to associate the annotation.

Description

This command adds annotations to objects returned by the *gui_create_vm_objects* command.

Layout view visual modes are used to color objects in the layout view based on certain criteria. You can use the *gui_update_vm_annotations* command to display not only object coloring but some additional annotations for the objects in a visual mode bucket.

Examples

To create a bucket that displays cells and a line connecting those cells to the location (0,0), enter code like the following example:

```
prompt> set objs [gui_create_vm_objects $cells]
   foreach_in_collection o $objs {
      set c [get_attribute $o core_obj]
      gui_update_vm_annotations $o -type line -add [list {0 0} $c]
   }
prompt> gui_create_vmbucket -vmname $vm -name $bucket -color red
 -collection $objs
```

See Also

---

gui_view_port_history

Does the gui_view_port_history operations.

Syntax

gui_view_port_history

```
[-window window_name]
    [-next]
    [-previous]
    [-add name]
    [-to  name]
```

Feedback

```
    [-list_names]
    [-rect bounding box]
    [-delete_names name]
    [-isprevious]
    [-isnext]
    [-dialog]
    [-tcl_list]
    [-help_cmd]
```

Arguments

`-window fwindow_name`

Give the name of a window. this is required option except if you use *-dialog* option.

`-next`

Specify if you want to go to previous stored view port history. If you use *-next* option you can not use any other option except *-window* option: they are mutually exclusive.

`-previous`

Specify if you want to go to previous stored view port history. If you use *-previous* option you can not use any other option except *-window* option: they are mutually exclusive.

`-add name`

Current view port will be stored by this name. *-add* option can be combined with *-rect* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name.

If you use *-add* option you can not use any other option except *-window* and *-rect* option : they are mutually exclusive.

`-to name`

Give the name of a view port history already stored. If you use *-to* option you can not use any other option except *-window* option: they are mutually exclusive.

`-list_names`

Specify if you want to see list of names of all the named view port history. If you use *-list_names* option you can not use any other option except *-window* option: they are mutually exclusive.

`-delete_names name`

The already stored view port history with this name will be deleted. If you use *-delete_names* option you can not use any other option except *-window* option: they are mutually exclusive.

Feedback

`-rect` *`boundingbox`*

Adds give the bounding box (in design units) to unnamed view port history. The values should be given in following format. format: {{x1 y1} {x2 y2}} *-rect* option can be combined with *-add* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name. If you use *-add* option you can not use any other option except *-window* and *-add* option : they are mutually exclusive.

`-isnext`

return true returns true if there previous zoom history. If you use *-isnext* option you can not use any other option except *-window* option: they are mutually exclusive.

`-isprevious`

returns true if there next zoom history. If you use *-isprevious* option you can not use any other option except *-window* option: they are mutually exclusive.

`-dialog`

specify to invoke dialog for named view port history. If you use *-dialog* option you can not use any other option except *-help_cmd* option: they are mutually exclusive.

`-tcl_list`

return a tcl_list of named view port history If you use *-tcl_list* option you can not use any other option except *-window* option: they are mutually exclusive.

`help_cmd` *`help_command`*

Give a command which will be executed when help buttonis clicked in the dialog.

Description

This command store view port for the application. At least one option needs to be specified.

last 100 View ports will be stored in view port history, which can be accessed by specifying *-previous* and *-next* options.

When you use *-add* then the current view port will be stored by the given name in the to view port history.

when you use *-to* then the view port stored by this name will be shown and added to the view port history.

Examples

The following example zooms in to the given rectangle.

Feedback

```
fpc_shell> gui_view_port_history -rect {{-2232.321 -536.887} {141.286
 2175.807}}
```

The following example zooms to next .

```
fpc_shell> gui_view_port_history -next
```

The following example zooms to previous.

```
fpc_shell> gui_view_port_history -previous
```

The following example gives list of all the named zooms.

```
fpc_shell> gui_view_port_history -list_names
```

The following example puts the current zoom in to zoom history by given name.

```
fpc_shell> gui_view_port_history -add xyz
```

The following example zooms to already stored to zoom .

```
fpc_shell> gui_view_port_history -to xyz
```

The following example deletes an already stored to zoom.

```
fpc_shell> gui_view_port_history -delete xyz
```

---

gui_write_annotations

Saves annotations to a Tcl file.

Syntax

```
status gui_write_annotations
-file filename
[-append]
[-force]
[-compress method]
[annotations]
```

Data Types

```
filename      string
method        string
annotations   collection
```

Arguments

`-file filename`

Specifies the name of the file in which the tool saves the annotation script.

Feedback

`-append`

Append the annotation script to an existing file instead of creating a new one. The specified file must exist. This option cannot work with *-force*.

`-force`

Overwrite the specified file, if it exists, with the new one. This option cannot work with *-append*.

`-compress` *method*

Specifies the compression type to use when writing the file. By default, no compression is performed.

`annotations`

Specifies a collection of annotations to write. Get a collection of annotations with the gui_get_annotations command. If this option is not specified, then all the annotations with *global* window handle and *global* group type would be written by, annotations with specific window handle or group type are excluded.

Description

This command writes a collection of annotations to a Tcl script. The attribute -visible will only be exported if it is set as invisible.

Examples

```
Write out all global annotations.

prompt> gui_write_annotations -file my_annotations.tcl

Write out all annotations in Layout.1.

prompt> gui_write_annotations -file my_annotations.tcl \\
    [gui_get_annotations -window Layout.1]
```

See Also

- gui_add_annotation
- gui_get_annotations
- gui_remove_all_annotations
- gui_remove_annotations

---

gui_write_cell_location

Saves cell location information to a given file

Feedback

Syntax

```
string gui_write_cell_location file_name
```

Data Types

```
file_name string
```

Arguments

file_name

Specifies the file name to write.

Description

The *gui_write_cell_location* command writes a file containing the cell location information.

Examples

```
prompt> gui_write_cell_location myfile.cref
```

See Also

- gui_load_cell_displacement_vm

---

gui_write_charts_data

Write charts data

Syntax

```
status gui_write_charts_data
-view view_name
[ -file file_name ]
```

Data Types

```
view_name  string
file_name  string
```

Arguments

-view view_name

View to output data for.

-file file_name

Filename to output data to. If not specified then the the output is sent to the terminal.

Feedback

Description

Write charts data as a tcl script to terminal or a file.

This command allows the user to save the state of the plots in the current view to a tcl command which can be source'd to reproduce the plot.

Details of the models loaded for the view's plots, the views annotations, the plots and the plots annotations are saved.

Only the view and plot properties that have changed from their default values are saved.

Note: Only the filename, tcl variable or collection name of the model data can be saved so these external dependencies, file data, contents of the tcl variable, or contents of the collection will need to be recreated before the script can be used.

Examples

The following example writes view data to the file "view_data.tcl".

```
shell> gui_write_charts_data -view Charts.1 -file "view_data.tcl"
```

See Also

- gui_create_charts_model

---

gui_write_charts_image

Save charts plot or view to image file

Syntax

```
status gui_write_charts_image
-view view_name
-plot plot_name
-file string
```

Data Types

```
view_name  string
plot_name  string
```

Arguments

`-view view_name`

Charts view to save (all charts).

`-plot plot_name`

Single charts plot in view to save.

Feedback

`-file` *string*

Output filename.

The file suffix is used to determine type i.e. .png for PNG file or .svg for SVG file.

If the file suffix (converted to lower case) is not .png or .svg then PNG is used.

Description

Save charts plot or view to PNG or SVG image file.

Examples

The following example saves all charts in a view to a PNG file charts.png.

```
shell> gui_write_charts_image -view $view -file charts.png
```

---

gui_write_hierarchy_colors

Writes current hierarchy Module Boundary status and colors to a file.

Syntax

```
status gui_write_hierarchy_colors
-file file_name
```

Data Types

```
file_name  string
```

Arguments

`-file` *file_name*

Specifies the name of file to write.

Description

The *gui_write_hierarchy_colors* command writes current hierarchy Module Boundary status and colors to a file. Next time, you can source this file to restore hierarchy Module Boundary status and color.

Examples

The following examples writes current Module Boundary status and colors to a data file named color.tcl.

```
prompt> gui_write_hierarchy_colors -file color.tcl
```

See Also

- gui_explore_logic_hierarchy

Feedback

gui_write_timing_paths

Writes a persistent path data file containing a timing path collection.

Syntax

```
status gui_write_timing_paths
-file file_name
[-overwrite]
[-no_pocv]
[-tag tag_name]
[-comment comment]
paths
```

Data Types

```
file_name  string
tag_name   string
comment    string
paths      collection
```

Arguments

`-file file_name`

Specifies the name of the persistent path data file to write. By default, if the file already exists, the command exits without writing the file.

`-overwrite`

Specifies that file that already exists will be overwritten.

`-no_pocv`

Specifies that no POCV timing data should be saved.

`-tag tag_name`

Specifies a tag name for the timing path.

`-comment comment`

Specifies a user comment for the timing path file.

`paths`

Specifies the collection of timing paths to write.

Description

The *gui_write_timing_paths* command writes a persistent path data file containing the given path collection. The persistent path data file contains all the information needed to re-create those timing paths using the *gui_read_timing_paths* command.

Feedback

Examples

The following examples writes out a timing path collection to a persistent path data file named my.paths.

```
prompt> gui_write_timing_paths $paths -file "my.paths"
```

See Also

- gui_read_timing_paths

---

gui_write_user_map

write snapshot of current map mode data to file.

Syntax

string *gui_write_user_map*

```
-name mapName
-file outputFile
[-metadata]       (Export header only)
```

Data Types

mapName string

outputFile string

Arguments

`-map` *mapName*

Specifies the current Visual/Map Mode name in layout

`-file outputFile`

Specifies the name of output file. It can be a single file name(generated in previous working directory) or have a absolute path.

`-metadata`

This option indicates that a meta data section should be included in the output. The meta data contains basic information of the map.

For displaying the output data as a user-map, including the meta data is recommanded.

For processing the data without displaying as user-map or other purposes, this option should not be turned on.

Feedback

Description

Write snapshot of current map mode data into csv file. The map data is easier to read and adapt to other app. User map is a general feature and will not have all of the features of the map that was written only the basic data presentation and bucket settings.

Here's an example of the output file of cell density map:

```
#META_DATA
#type,name,property,value
#table,,tag,gui_write_user_map
#table,,app_name,icc2
#table,,version,"V1.0"

```

Examples

```
While the map is generated and presented in layout:

prompt>gui_wirte_user_map -map cellDensityMap -file cellden.csv
```

See Also

- gui_read_user_map
- gui_remove_user_map

---

gui_write_utable

Write the UserTable to file in native UserTable format.

Syntax

string *gui_write_utable*

```
-name         Table_Name
[-file        File_Name]
[-filter      Filter]
[-read_only]
[-overwrite]

Table_Name    String
File_Name     String
```

Arguments

`-name` *Table_Name*

The name of the user table to write out to a file.

`-file` *File_Name*

The name of the file to write the table to, by default the name of the table is used with the '.utable' extension.

`-filter` *Filter*

This argument allows you to filter the rows in the given table to only rows that match the filter. The filter expression is the same expression allowed in the GUI filter field of the UserTable GUI view.

Feedback

`-read_only`

This flag closes the table that has been written out and then re-opens it in read-only (streaming) mode which can save a lot of system memory if the table is huge.

`-overwrite`

This flag will force the destination file to be overwritten.

Description

This command writes the given table name to a file in the native user table format, preserving all meta data (filter, sort order and column information). The UserTable file can then be later re-opened to copy the information back into memory or opened in a read-only (streaming) mode using the command **gui_open_utable**.

Examples

The following example writes out the given table to a file name equal to the table name plus the extension '.utable'.

```
shell> gui_write_utable -name my_table
```

The following example writes out the given table (overwrites the file if necessary) and then closes the table in memory and re-opens it in read-only (streaming) mode.

```
shell> gui_write_utable -name my_table -read_only -overwrite
```

See Also

- gui_append_utable
- gui_change_selection_utable
- gui_close_utable
- gui_create_utable
- gui_export_utable
- gui_import_utable
- gui_open_utable
- gui_show_utable

Feedback

gui_write_window_image

Saves an image of a view or toplevel window in the specified image file

Syntax

```
status gui_write_window_image
-file filename
[ -format image_format ]
[ -window window_name ]
[ -palette palette_side ]
[ -size window_size ]
[ -clip ]
[ -adjust_aspect ]
[ -data_file sbool ]
[ -report string ]
[ -data_values name_value_pairs ]
[ -add_to_image_view ]
```

Data Types

```
filename          string
image_format      string
window_name       string
palette_side      string
window_size       string
name_value_pairs  string
```

Arguments

`-file filename`

Specifies the name of the file in which the tool saves the window image.

If you include a file name extension, it determines the image format unless you also specify the *-format* option.

If the extension is 'idf' then an image data file is generated where the saved image is encoded in the file as 'Base 64' encoded data.

If no filename is specified then the "gui_image.<format>" will be used where <format> is the specified or default file format.

`-format image_format`

Specifies the image format to be used in the file. The default value is png.

Note that if the format that you specify with the *-format* option is different from the format specified by the file name extension, the *-format* value takes precedence and the tool appends an additional extension to the file name.

Feedback

`-window` *`window_name`*

Specifies the name of the window for which you want to save an image in the specified image file.

You can view a list of the window names for all the open toplevel and view windows by using the *gui_get_window_ids* command.

By default, the tool saves an image of the most recently active view window.

`-palette` *`palette_side`*

Specifies the type of side of the palette to take snapshot of.

Palette types can be listed with *gui_get_palette_types* command.

Side can be one of: "left", "right", "top" or "bottom".

`-size` *`window_size`*

The size of the image to be generated. If not specified then the full window size is used.

`-clip`

Specifies that the generated image should be clipped to remove any extra margin.

Note: only layout view currently supports this option.

`-adjust_aspect`

Specifies that the size of the image should be adjusted to match the aspect ratio of the view.

`-data_file` *`sbool`*

Specifies that an extra data file should be written containing details of the generated snapshot that can be used in the GUI Image View.

The image file will be generated as normal and is referenced by the image data file.

The data filename is the same as the image file with the suffix replaced with 'idf' suffix (Image Data File). If the image file name is not specified then the 'gui_image.idf' filename is used.

`-report` *`string`*

Specifies a short description for the image data being written.

`-data_values` *`name_value_pairs`*

Specifies extra name value pairs to be added to the data file.

Feedback

By default the value is assumed to be a string. If the user wishes to add numeric value they can add a suffix to the value string. Use <value;>#real for real value or <value;>#integer for integer value.

`-add_to_image_view`

Specifies the the resultant image is automatically added to the current image view.

If no image view exists it will be created.

Description

The *gui_write_window_image* command takes a snapshot of a specified toplevel window or child view window in a specified image format and writes the result to a specified file.

Image Data File (.idf)

The command can also generate a special Image Data File ('.idf' file) which contains meta data about the image. The image data can either be encoded directly as meta data in the data file or using meta data with the image file name.

If the filename used for the *-file* option has a '.idf' suffix then the an image data file will be generated and the saved image will be encoded in it.

If the *-data_file* option is specified then an image data file will be generated with an external reference to the generated image filename.

The generated image data file contains a list of name value pairs with the following names generated by default:

- image : image data (if encoded image data is generated)
- image_file : image filename (if separate image file generated)
- directory : current directory when saved
- format : image file format
- date : date file written
- size : image pixel size
- window : window type or view type image generated from
- coords : view coordinate system (if supported)
- report : single line description of image

Examples

The following example writes a snapshot of the TopLevel.1 window to an image file "snapshot.png".

Feedback

```
shell> gui_write_window_image -window TopLevel.1 -file snapshot.png
```

The following example writes a snapshot of the Layout.1 view to an image file "layout.png" of size 800 pixels by 600 pixels.

```
shell> gui_write_window_image -window Layout.1 -file layout.png -size
 {800 600}
```

The following example writes an image data file with the snapshot of the Layout.1 view encoded as a bmp file in it.

```
shell> gui_write_window_image -window Layout.1 -file layout.idf -format
 bmp
```

The following example writes an image data file with the snapshot of the Layout.1 view referenced by it.

```
shell> gui_write_window_image -window Layout.1 -file layout.png
 -data_file 1
```

The following example writes an image data file with meta data on map mode with the snapshot of the Layout.1 view ireferenced by it.

```
shell> gui_write_window_image -window Layout.1 -data_file 1 \\
  -data_values {{map_mode congestion}} -report {congestion map}
```

See Also

- gui_get_window_ids
- gui_get_current_window

---

gui_zoom

Change the viewport of a view

Syntax

gui_zoom

-window *window* [-fit | -exact] [-full] [-full_top] [-selection] [-rect *{{lx ly} {ux uy}}*] [-factor *factor*] [-at_point *{x y}*] [-clct *clct*] [-zoom_in_mode] [-zoom_out_mode] [-select_mode]

```
window          String
rect            String
factor          Float
```

Feedback

Arguments

`-window` *window*

window specifies the window of which this command should change the viewport.

`-full`

Zoom such that all objects are visible.

`-full_top`

Zoom such that the entire top design is visible.

`-factor` *factor*

Keep the center of the viewport and zoom by factor *factor*. A *factor*" > 1 causes a zoom-in, a *factor*" < 1 causes a zoom-out. The argument must be greater than zero.

`-at_point` *{x y}*

Can only be specified with -factor argument. If supplied, zoom is performed at specified point instead of viewport center. The option is not supported by all window types.

`-fit`

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to not over zoom. Will zoom a reasonable distance away from the rectangle or objects being zoomed. The definition of "reasonable" is window dependent. This argument is mutually exclusive with -exact.

`-exact`

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to zoom exactly to the arguments. This argument is mutually exclusive with -fit.

`-selection`

Zoom such that all selected objects that are represented in the window are visible and if possible are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

`-rect` *{{lx ly} {ux uy}}*

Zoom such that the window shows the rectangle *rect* in its viewport. What coordinates are assumed for *rect* are dependent on the window. If neither -fit or -exact is supplied, -exact is assumed.

Feedback

`-clct` *clct*

Zoom such that all objects in *clct* that are represented in the window are visible and if possible, are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

`-zoom_in_mode`

Put the window in zoom-in mode.

`-zoom_out_mode`

Put the window in zoom-out mode.

`-select_mode`

Put the window in selection mode.

Description

The *gui_zoom* controls the viewport of a view that supports zooming. Not all views need to support all of the functionality provided by the interface of this command.

Examples

The following example has the layout view show the entire design and then zooms in by a factor of 2, i.e. only a quarter of the area of the design is still visible:

```
gui_zoom -window Layout.1 -full
gui_zoom -window Layout.1 -factor 2
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}}
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}} -fit
gui_zoom -window Layout.1 -selection -exact
```

---

gui_zoom_all_layouts_to_current_view

Rescales all layout views to the current view.

Syntax

gui_zoom_all_layouts_to_current_view

Arguments

None.

Description

The command sets the zoom factor of all layout views to the zoom factor of current layout view.

Examples

```
prompt> gui_zoom_all_layouts_to_current_view
```

Feedback

See Also

- gui_zoom

---

gui_zoom_to_selected_errors

Layout window zoom to errors selected in the error browser.

Syntax

string *gui_zoom_to_selected_errors*

Description

If you have selected the errors in the error browser, you can execute this command to have layout zoom to the selected errors.

Examples

If you select errors, then perform layout zooming operations, the following command will force layout to zoom to selected errors: gui_zoom_to_selected_errors

See Also

- gui_error_browser

---

help

Displays quick help for one or more commands.

Syntax

```
string help
[-verbose]
[-groups]
[pattern]
```

Feedback

Data Types

pattern string

Arguments

-verbose

Displays the command options; for example *command_name -help*.

-groups

Displays a list of command groups only.

pattern

Displays commands matching the specified pattern.

Description

The *help* command is used to get quick help for one or more commands or procedures. This is not the same as the *man* command that displays reference manual pages for a command. There are many levels of help.

By typing the *help* command, a brief informational message is printed followed by the available command groups.

List all of the commands in a group by typing the group name as the argument to *help*. Each command is followed by a one-line description of the command.

To get a one-line help description for a single command, type *help* followed by the command name. You can specify a wildcard pattern for the name; for example, all commands containing the string "alias". Use the *-verbose* option to get syntax help for one or more commands. Use the *-groups* option to show only the command groups in the application. This option cannot be combined with any other option.

Examples

The following example lists the commands by command group:

```
prompt> help
Specify a command name or wild card pattern to get help on individual
commands. Use the '-verbose' option to get detailed option help for a
command. Commands also provide help when the '-help' option is passed to
the command.'

You can also specify a command group to get the commands available in
that group. Available groups are:

  Procedures:                Miscellaneous procedures
  Help:                      Help commands
  Builtins:                  Generic Tcl commands
 ...
```

Feedback

The following example displays the list of procedures in the Procedures group:

```
prompt> help procedures
 ls                 # List files
 sh                 # Execute a shell command
```

The following example uses a wildcard character to display a one-line description of all commands beginning with *a*:

```
prompt> help a*
 alias                # Create a command which expands to words.
 append               # Builtin
 array                # Builtin
```

This example displays option information for the *source* command:

```
prompt> help -verbose source
 source               # Read a file and execute it as a script
   [-echo]                (Echo all commands)
   [-verbose]             (Display intermediate results)
   file_name              (Script file to read)
```

---

help_app_options

Displays the help information for application options.

Syntax

help_app_options

```
[-verbose]
[-scope scope]
[-category category]
[patterns]
```

Data Types

```
scope        string
category     string
patterns     string
```

Feedback

Arguments

`-verbose`

Displays the detailed information on the application options. This is an optional option. If this option is not specified, the information displayed is just the option name and the help string.

`-scope` *scope*

Specifies the scope of the application options for which the help string is to be displayed. This is an optional option. If this option is not specified, the help string for application options from both the global scope and design scope will be displayed.

`-category` *category*

Specifies the category of application options for which the help string is to be displayed. The help string for all the application options belonging to the specified category will be displayed.

patterns

Specifies a pattern for the option names. A pattern can include the wildcard characters asterisk (*) and question mark (?). "*" will match zero or more of any character, and "?" will match any single character. If this option is specified, the command displays the help string for only those application option names that match the specified pattern. If not specified, includes all the options.

Description

This command displays the help information for the application options whose names match the specified pattern.

The default behavior is to display the names of all the categories of registered application options.

Examples

The following example shows the default behavior

```
prompt> help_app_options
Categories of the registered application options are:
  abstract
  budget
  calc
  clock_opt
  constraint
  \...
  upf
  verilog
```

Feedback

The following example displays the help string of all application options belonging to category 'verilog'.

```
prompt> help_app_options -category verilog
verilog.default_user_label                # Default user label to create
 the design in
verilog.enable_vpp                        # Enable Verilog pre-processor
verilog.keep_unconnected_cells            # Keep unconnected cells
verilog.keep_unconnected_nets             # Keep unconnected nets
```

The following example displays the help string for application options that are global scoped, belong to category 'shell' and match the pattern '*product*'

```
prompt> help_app_options -scope global -category shell *product*
shell.product_abbreviation                # Specifies the abbreviated
 string
for the product for this application.
shell.product_build_date                  # Specifies the build date of
 this
application.
shell.product_name                        # Specifies the name for the
 product
for this application.
shell.product_version                     # Specifies the version of this
application.
```

The following example displays a detailed information for the application option 'route.detail.max_antenna_pin_count'

```
prompt> help_app_options route.detail.max_antenna_pin_count -verbose
name
 route.detail.max_antenna_pin_count
value_type                                integer
default_value                             -1
help                                      fix antenna on nets with number
 of
                                          pins less than given value
status                                    basic
minimum_value                             -1
maximum_value                             1000000
allowed_values                            --
app_var_name                              --
is_obsolete                               false
is_global_only                            false
is_read_only                              false
is_persistent                             true
is_subscripted                            false
```

help_attributes

Display help for attributes and object types

Syntax

string *help_attributes* [-verbose]

[-application] [-user] [*class_name*] [*attr_pattern*]

```
string  class_name
string  attr_pattern
```

Arguments

`-verbose`

Display attribute properties.

`-application`

Only display application defined attributes.

`-user`

Only display user defined attributes.

`class_name`

Object class to retrieve help for.

`attr_pattern`

Show attributes matching pattern.

Description

The *help_attributes* command is used to get quick help for the set of available attributes. When this command is run with no arguments a brief informational message is printed followed by the available object classes.

Feedback

Examples

```
prompt> help
cci_test> help_attributes
Specify an object type and an optional wild card pattern to get
 information
on the available attributes defined for the specified object type. Use
 the
-verbose option to get detailed information on the attributes

The available object types are:

  cell        net       pin
  ...
```

See Also

---

hier_route_eco

Performs ECO routing on the subblocks open for optimization.

Syntax

status *hier_route_eco*

`[-work_dir` *directory*`]`

Data Types

directory string

Arguments

`-work_dir` *directory*

Specifies the directory to put scripts and log files for subblock runs.

Description

The *hier_route_eco* command performs ECO routing on the subblocks linked to the current design which are enabled for optimization. This command is intended to be run right after route_opt and is specifically created for the THO flow.

Examples

```
prompt> hier_route_eco
```

Feedback

```
prompt> hier_route_eco -work_dir output_dir
```

See Also

- route_eco
- set_editability
- route.detail.eco_max_number_of_iterations

---

history

Displays or modifies the commands recorded in the history list.

Syntax

string *history*

```
[-h]
[-r]
[argument_list]
```

Data Types

argument_list list

Arguments

`-h`

Displays the history list without the leading numbers. You can use this for creating scripts from existing history. You can then source the script with the *source* command. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

`-r`

Reverses the order of output so that most recent history entries display first rather than the oldest entries first. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

argument_list

Additional arguments to *history* (see DESCRIPTION).

Description

The *history* command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." The most commonly used forms of the command are described below. You can combine each with either the *-h* or *-r* option, but not both.

Feedback

- With no arguments, the *history* command returns a formatted string (intended for you to read) giving the event number and contents for each of the events in the history list.
- If a single, integer argument *count* is specified, only the most recent *count* events are returned. Note that this option is a nonstandard extension to Tcl.
- Initially, 20 events are retained in the history list. You can change the length of the history list using the following:

  history keep count

Tcl supports many additional forms of the *history* command. See the "Advanced Tcl History" section below.

Examples

The following examples show the basic forms of the *history* command. The first is an example of how to limit the number of events shown using a single numeric argument:

```
prompt> history 3
     7  set base_name "my_file"
     8  set fname [format "%s.db" $base_name]
     9  history 3
```

Using the *-r* option creates the history listing in reverse order:

```
prompt> history -r 3
     9  history -r 3
     8  set fname [format "%s.db" $base_name]
     7  set base_name "my_file"
```

Using the *-h* option removes the leading numbers from each history line:

```
prompt> history -h 3
set base_name "my_file"
set fname [format "%s.db" $base_name]
history -h 3
```

Advanced Tcl History

The *history* command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as

Feedback

an "event." When specifying an event to the *history* command, the following forms may be used:

- A number, which if positive, refers to the event with that number (all events are numbered starting at 1). If the number is negative, it selects an event relative to the current event; for example, *-1* refers to the previous event, *-2* to the one before that, and so on. Event *0* refers to the current event.
- A string selects the most recent event that matches the string. An event is considered to match the string either if the string is the same as the first characters of the event, or if the string matches the event in the sense of the *string match* command.

The *history* command can take any of the following forms:

history

Same as *history info*, described below.

history add command [exec]

Adds the *command* argument to the history list as a new event. If *exec* is specified (or abbreviated), the command is also executed and its result is returned. If *exec* is not specified, an empty string is returned.

history change newValue [event_number]

Replaces the value recorded for an event with *newValue*. The *event_number* specifies the event to replace, and defaults to the *current* event (not event *-1*). This command is intended for use in commands that implement new forms of history substitution and want to replace the current event (that invokes the substitution) with the command created through substitution. The return value is an empty string.

history clear

Erases the history list. The current keep limit is retained. The history event numbers are reset.

history event [event_number]

Returns the value of the event given by *event_number*. The default value of *event_number* is *-1*.

history info [count]

Returns a formatted string, giving the event number and contents for each of the events in the history list except the current event. If *count* is specified, then only the most recent *count* events are returned.

Feedback

history keep [count]

Changes the size of the history list to *count* events. Initially, 20 events are retained in the history list. If *count* is not specified, the current keep limit is returned.

history nextid

Returns the number of the next event to be recorded in the history list. Use this for printing the event number in command-line prompts.

history redo [event_number]

Reruns the command indicated by *event* and returns its result. The default value of *event_number* is *-1*. This command results in history revision. See the following section for details.

History Revision

Pre-8.0 Tcl had a complex history revision mechanism. The current mechanism is more limited, and the *substitute* and *words* history operations have been removed. The *clear* operation was added.

The *redo* history option results in much simpler "history revision." When this option is invoked, the most recent event is modified to eliminate the history command and replace it with the result of the history command. If you want to redo an event without modifying the history, use the *event* operation to retrieve an event, and use the *add* operation to add it to history and execute it.

---

hyper_route_opt

perform post route optimization on the routed design

Syntax

hyper_route_opt

Description

This command optimizes the routed design for timing, area and power, then it performs concurrent legalization, and eco routing, produces an optimized, legalized and eco routed design.

hyper_route_opt is an integrated opto and eco based post route optimization technology for faster convergence. This technology is different from route_opt which usually requires several iterations for convergence.

hyper_route_opt final phase ends with true footprint based optimization by default, which sizes the cells in the way that only true physical footprint equivalent cells will be

Feedback

introduced, so no additional legalization and eco routing required, for a better timing closure. In order to disable true footprint, use the route_opt.flow.size_only_mode option.

Note: The design must be routed before hyper_route_opt, no detail routing is performed inside hyper_route_opt also, make sure no open nets in the design, otherwise, it will impact the QoR convergence.

Mixed usage of hyper_route_opt and normal route_opt is not allowed. You can use the targeted endpoint based route_opt after hyper_route_opt

ADDITIONAL INFORMATION

CCD optimization is disabled by default. To enable, use the route_opt.flow.enable_ccd app_option

You can enable the PBA based optimization as well during hyper_rout_opt. When enabled, PBA based analysis and optimization is enabled throughout the flow.

For designs targeting FMAX, you can enable high timing effort and fmax optimization effort for CCD optimization with below app options set_app_options -name ccd.timing_effort -value high set_app_options -name ccd.fmax_optimization_effort -value high

ENABLING CHIP FINISHING COMMANDS AND SAVING INTERMEDIATE DESIGN

A Synopsys TCL proc "snps_hyper_route_opt_post_eco" is provided as callback to enable the following features in the middle of hyper_route_opt 1. chip finishing commands such as metal fill, filler insertion. 2. save intermediate database by including save_block.

Using the intermediate design saved via the above TCL proc, you can resume hyper_route_opt from where it was left. see example section on how to use this procedure.

LAST MILE PPA CLOSURE AFTER hyper_route_opt

hyper_route_opt as a single command is an out of the box technology that is expected to produce a design converged in all QoR metrics. However, in situations where further PPA improvement is needed, you can use targeted endpoint based route_opt (TEP) to optimize a specific QoR metric like setup, hold, or ldrc as shown in the examples section.

For additional route DRC convergence, you can run incremental detail routing using "route_detail -incremental" command.

Examples

Example for snps_hyper_route_opt_post_eco proc for chip finishing and save_block commands ----------

proc snps_hyper_route_opt_post_eco { } { # define signoff metal fill in the proc, it will be called in the middle of hyper_route_opt signoff_create_metal_fill

to save a block in the middle of hyper_route_opt save_block -as hropt_intermediate -force } hyper_route_opt exit

Feedback

to resume hyper_route_opt from saved block [another session] open_block hropt_intermediate hyper_route_opt ; # resumes from where it was left while saving.

Example for running TEP after hyper_route_opt ----------

run hyper_route_opt hyper_route_opt

run targeted endpoint route_opt ## To enable targeted CCD WNS for FMAX design set_app_options -list {route_opt.flow.enable_ccd true} ; # optional for FMAX set_app_options -list {route_opt.flow.enable_targeted_ccd_wns_optimization true} ; # optional for FMAX

set_route_opt_target_endpoints -setup_endpoints_collection collection_of_setup_endpoints route_opt

set_route_opt_target_endpoints -hold_endpoints_collection collection_of_hold_endpoints route_opt

i

identify_channels

Identifies channels between specified objects. The supported objects are cells, site rows, placement blockages, routing blockages, and wires.

Syntax

status *identify_channels*

```
[-output_filename file_name]
[-horizontal_threshold horizontal_threshold]
[-vertical_threshold vertical_threshold]J
[-cross_area]
```

Feedback

```
[-cross_area_width cross_area_width]
[-cross_area_height cross_area_height]
[collection_of_objects]
```

Data Types

```
file_name              string
horizontal_threshold   double
vertical_threshold     double
cross_area_width       double
cross_area_height      double
collection_of_objects  collection
```

Arguments

`-output_filename` *file_name*

Specifies the file name in which to write out the identified channels. By default, the command writes the channel information to "channels.txt".

`-horizontal_threshold` *horizontal_threshold*

Specifies the threshold value for horizontal channels. Channels taller than *horizontal_threshold* are not reported. If you specify *-horizontal_threshold* without specifying *-vertical_threshold*, only horizontal channels are reported.

`-vertical_threshold` *vertical_threshold*

Specifies the threshold value for vertical channels. Channels wider than *vertical_threshold* are not reported. If you specify *-vertical_threshold* without specifying *-horizontal_threshold*, only vertical channels are reported.

`-cross_area`

Identify cross area channels. Cross area channels have both a height and a width.

`-cross_area_width` *cross_area_width*

Specifies the width threshold value for cross area channels. Cross area channels with a width smaller than *cross_area_width* are not reported.

`-cross_area_height` *cross_area_height*

Specifies the height threshold value for cross area channels. Cross area channels with a height smaller than *cross_area_height* are not reported.

collection_of_objects

Specifies a collection of objects. The supported objects are cells, site rows, placement blockage, routing blockage, and wires.

Feedback

Description

This command identifies channels between specified objects and writes the channel coordinates to channels.txt. The *-horizontal_threshold* and *-vertical_threshold* options specify an upper limit to the height and width of the channels; channels outside the limit are not reported.

The output format written to channels.txt of channel is

```
direction (xlo ylo) (xhi yhi)
```

For example,

```
vertical (1339.255 367.195) (1392.445 489.325)
```

Examples

The following example writes out a channel file named channels.txt for channels between cells SD_RFIFO_RAM and SD_WFIFO_RAM, site row unit_row_2, placement_blockage PB1, routing blockage RB1, and wires PATH_14_653.

```
prompt> set objects [get_cells "SD_RFIFO_RAM SD_WFIFO_RAM"]
prompt> append_to_collection objects [get_site_rows "unit_row_2"]
prompt> append_to_collection objects [get_placement_blockages "PB1"]
prompt> append_to_collection objects [get_routing_blockages "RB1"]
prompt> append_to_collection objects [get_shapes "PATH_14_653"]
prompt> identify_channels $objects
```

The following example writes out a channel file named channelObjects.txt and displays the file for channels between selected objects.

```
prompt> identify_channels [get_selection] -output_filename
 channelObjects.txt
prompt> sh cat channelObjects.txt
horizontal (1.6 1392.07) (352.165 1408.07)
horizontal (442.7 1408.07) (793.265 1424.07)
vertical (352.165 1424.07) (442.7 1616.515)
vertical (352.165 1648.515) (442.7 1856.96)
```

The following example writes out horizontal channels with a height less than 10 microns and vertical channels with a width less than 5 microns.

```
prompt> identify_channels [get_selection] -horizontal_threshold 10
 -vertical_threshold 5
```

See Also

- create_pg_strap

Feedback

identify_lib_cell_families

Identify initial library cell families of libraries.

Syntax

status *identify_lib_cell_families*

```
-library library_object_list | -libset libset_name_string
```

Data Types

```
library_object_list  list-of-library-objects
libset_name_string   string
```

Arguments

`-library` *library_object_list*

A set of libraries, where the initial library cell families will be identified.

`-libset` *libset_name_string*

A libset including a set of libraries, where the initial library cell families will be identified.

Description

This command identifies initial library cell families of the given libraries, grouped by the library cells' functionality and other optional properties.

For example, if a library includes the following library cells:

```
INVD1, INVD2, INVD4, NAND2D1, NAND2D2, NOR2D1, NOR2D2, FFD1, FFD2,
 SCANFFD1, SCANFFD2, LATCHD1, LATCHD2
```

This command checks every library cells and then defines the following initial library cell families:

```
Initial Family 1 : {INVD1 INVD2 INVD4}
Initial Family 2 : {NAND2D1 NAND2D2}
Initial Family 3 : {NOR2D1 NOR2D2}
Initial Family 4 : {FFD1 FFD2}
Initial Family 5 : {SCANFFD1 SCANFFD2}
Initial Family 6 : {LATCHD1 LATCHD2}
```

If the library has been lexical classified, the lexical attributes can be optionally considered as additional conditions for initial family identifications.

Those lexical attributes can be useful for separating library cells with same functionality into different initial families. The setting is via the following app-options for each lexical attribute. By default, only "lexical_cell_prefix_name" is considered.

Feedback

Default: True

---

identify_multibit

Identifies multibit banking opportunities and writes out a register or mv_cell banking script.

Syntax

status *identify_multibit*

```
-register | -mv_cell
-output_file file_name | -apply
[-input_map_file file_name]
[-slack_threshold slack_value]
[-exclude_instance exclude_cells]
[-exclude_library_cells library_cells]
[-no_dft_opt]
[-cells list_of_cells]
```

Data Types

```
file_name       string
slack_value     float
exclude_cells   list or collection
library_cells   list or collection
list_of_cells   list or collection
```

Arguments

`-register`

Allows you to identify the groups of registers that can be replaced by multibit registers. You must specify either the *-register* or *-mv_cell* option.

`-mv_cell`

Allows you to identify groups of level_shifters or isolation cells that can be replaced by multibit level_shifter or isolation cell. You must specify either the *-register* or *-mv_cell* option.

`-output_file file_name`

Specifies the name of the output file that contains the generated banking commands. The output file contains a series of *create_multibit* commands.

Feedback

The output file can be sourced back into the tool to replace single-bit cells with multibit cells. You must specify either the *-output_file* or *-apply* option.

`-apply`

If this option is specified, tool modifies the netlist by replacing identified groups of single-bit cells with multibit cells instead of generating the output script file. You must specify either the *-output_file* or *-apply* option.

`-input_map_file` *`file_name`*

Specifies the name of the input map file that contains functional group information and mapping information about which multibit register bank replaces which single-bit registers for each functional group.

If you do not specify this option, the command identifies the single-bit registers that can be replaced by available multibit registers in the libraries based on the functional information of the library cells; the tool then uses that information to control mapping.

This option can be used only when you are using the *-register* option. The format for the input map file is described in the DESCRIPTION section of this man page.

`-slack_threshold` *`slack_value`*

Specifies the slack value for a register to be considered for banking. Registers having slack value below this number is ignored for banking. By default tool consider all registers for banking. This option can be used only when you are using the *-register* option.

`-exclude_instance` *`exclude_cells`*

Specifies the list of instances to be ignored for grouping.

`-exclude_library_cells` *`library_cells`*

Specifies the list of library cells whose instances are ignored for grouping.

`-no_dft_opt`

This option disables the call to the *optimize_dft* command. If this option is not used, the netlist might get modified.

`-cells` *`list_of_cells`*

Specifies the list of single-bit cells, multibit cells or both to be considered for grouping.

Description

The *identify_multibit* command identifies groups of single-bit registers or mv_cells that can be replaced by multibit registers or mv_cells and then either modifies the netlist

Feedback

accordingly or generates a banking script file which can then be sourced back into the tool to replace single-bit cells with multibit cells. For high banking ratio consideration, the *optimize_dft* command is employed at the beginning by default, which might modify the netlist.

The following are the details about required format of the file specification using option *-input_map_file*. You can specify the input map file sequence as shown:

```
reg_group_name {list_of_reference_of_single_bit_flops }
bits { number_of_instances ref_multibit_flop } { ... }
bits { number_of_instances ref_multibit_flop } { ... }
```

Where *reg_group_name* specifies the name of the register group, *list_of_reference_of_single_bit_flops* specifies the list of references of single-bit registers. *bits* specifies the number of single-bit registers in a group to be replaced, *number_of_instance* specifies the number of multibit registers to be used, and *ref_multibit_flop* specifies the reference multibit library cell to be used.

For example:

```
reg_group_1 {REGX1 REGX2 REGX4}
2 {1 MREG2}
3 {1 MREG2}
4 {1 MREG4}
5 {1 MREG4}
6 {1 MREG2} {1 MREG4}
reg_group_2 {REGNX1 REGNX2 REGNX4}
2 {1 MREG2N}
3 {1 MREG2N}
4 {1 MREG4N}
5 {1 MREG4N}
6 {1 MREG2N} {1 MREG4N}
```

reg_group_1 {REGX1 REGX2 REGX4} means that single-bit registers whose reference is either REGX1, REGX2, or REGX4 can be grouped together. *4 {1 MREG4}* specifies that a group of four single-bit registers can be replaced by one cell whose reference is MREG4. Similarly, *6 {1 MREG2} {1 MREG4}* means a group of six single-bit registers can be replaced using one instances of MREG2 and one instance of MREG4.

You can include a comment using the # character in the input map file. Lines beginning with the # character to the end of the line is treated as a comment.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example uses the *identify_multibit* command to generate the banking script.

Feedback

```
prompt> identify_multibit -register
   -input_map_file ./input.map -output_file ./create_bank.out
1
```

See Also

- create_multibit
- split_multibit

---

identify_on_edge_macros

The command identifies certain hard macros as on_edge macros. The identified on_edge macros are highlighted, which can be used as debugging information for ML hybrid macro placement.

Syntax

status *identify_on_edge_macros*

`[-ratio on_edge_ratio]`

Data Types

on_edge_ratio float

Arguments

`-ratio`

Specify the ratio of on_edge macros over all macros. Without the option, the command decides the ratio automatically.

Description

The command identifies certain hard macros as on_edge macros. The identified on_edge macros are highlighted. The command uses the same engine as the one in the ML macro placement command *place_macro_ml*. Users can apply this command to see the identified on_edge macros after performing ML hybrid macro placement.

Examples

The following example identifies on_edge macros.

```
prompt> identify_on_edge_macros
```

The following example identifies on_edge macros with on_edge ratio 0.5.

```
prompt> identify_on_edge_macros -ration 0.5
```

---

implement_topology_repeaters

Place existing registers and/or insert new buffers based on unified topology constraints.

Syntax

status *implement_topology_repeaters*

```
[-topology_plans topology_plan_list]
[-cell_prefix prefix]
[-net_prefix prefix]
```

Data Types

```
topology_plan_list    list
prefix                string
```

Arguments

`-topology_plans`

Specifies a list of topology plans to place registers and/or insert buffers/inverter pairs. The list may contain topology plan names, patterns, or collections. A collection may be specified by using the *get_topology_plans* command.

`-cell_prefix`

Specifies the prefix to be used for new buffers/inverter pairs that are inserted in the netlist. By default, the command uses "cir_cell" as the prefix.

`-net_prefix` *prefix*

Specifies the prefix to be used for new nets that are created when buffers/inverter pairs are inserted in the netlist. By default, the command uses "cir_net" as the prefix.

Description

This command places registers and/or inserts buffers/inverter pairs based on the topology plans specified by the *-topology_plans* option. The command places registers associated to sequential type topology repeaters firstly and then inserts new buffers/inverter pairs for repeater type topology repeaters. When the placement fails, the command will not insert new buffers/inverter pairs.

By default, each newly added buffer/net has a name beginning with the prefix cir_cell/cir_net and ending with a numeric suffix. To override the automatic name generated by the tool, use the *-cell_prefix* and the *-net_prefix* options.

Feedback

The command supports both single load and multiple loads nets.

Examples

The following example implement the topology plans specified with the *-topology_plans* option.

```
prompt> implement_topology_repeaters -topology_plans [get_topology_plans
 topo*]
```

The following example uses the *-cell_prefix* and the *-net_prefix* options to set the prefix of newly added cells and nets.

```
prompt> implement_topology_repeaters -topology_plans topo_0 -cell_prefix
 topo_cell -net_prefix topo_net
```

---

index_collection

Given a collection and an index into it, if the index is in range, create a new collection containing only the single object at the index in the base collection. The base collection remains unchanged.

Optionally, a second index can be passed which creates a new collection with the objects between the two indices in the base collection. Makes an implicit assumption that index<=index2

Syntax

collection *index_collection*

Feedback

```
collection1
index
[index2]
[step]
```

Data Types

```
collection1          collection
index                index
index2               index
step                  int
```

Arguments

collection1

Specifies the collection to be searched.

index

Specifies the index into the collection.

The index is either a simple integer to specify the offset from the start of the collection or the string "end" optionally followed by a negative integer to specify the offset from the end of the collection.

For the start offset case the value must range from 0 to *sizeof_collection* - 1. For the end offset case the negative integer (if specified) must range from 0 to -(*sizeof_collection* - 1).

index2

Specifies an optional second index into the collection.

Specifies a second index to create a collection of a range of objects from the base collection, defined by the two indices [index, index2] (boundaries inclusive)

step

Specifies the step increment from index to index2. By default 1 is used.

Description

You can use the *index_collection* command to extract a single object from a collection. The result is a new collection containing only that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index.

The range of indices is from 0 to one less than the size of the collection. If the specified index is outside that range, an error message is generated.

Commands that create a collection of objects do not impose a specific order on the collection, but they do generate the objects in the same, predictable order each time.

Feedback

Applications that support the sorting of collections allow you to impose a specific order on a collection.

You can use the empty string for the *collection1* argument. However, by definition, any index into the empty collection is invalid. Therefore, using the *index_collection* command with the empty collection always generates the empty collection as a result and generates an error message.

Note that not all collections can be indexed.

Examples

The following examples from PrimeTime use the *index_collection* command to extract the first, second, last and penultimate object of a collection.

```
pt_shell> set c1 [get_cells {u1 u2 u3}]
{"u1", "u2", "u3"}
pt_shell> query_objects [index_collection $c1 0]
{"u1"}
pt_shell> query_objects [index_collection $c1 1]
{"u2"}
pt_shell> query_objects [index_collection $c1 0 1]
{"u1", "u2"}
pt_shell> query_objects [index_collection $c1 end]
{"u3"}
pt_shell> query_objects [index_collection $c1 end-1]
{"u2"}
pt_shell> query_objects [index_collection $c1 end-1 end]
{"u2", "u3"}
```

---

infer_supply_from_pg_net

Infer supply net connections to leaf PG pins in power intent based on their existing net connections in the PG netlist.

Syntax

status *infer_supply_from_pg_net*

```
[-create_supply_port]
[-verbose]
```

Feedback

Arguments

`-create_supply_port`

If specified, supply net connection translation into the power intent may entail creation of supply ports in certain specific cases such as when there are domain dependent supply nets or when connecting across scopes.

`-verbose`

Prints the details for the inference information for each pin.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

---

infer_switching_activity

Infers the switching activity on the drivers of special control input pins in the current design.

Syntax

int *infer_switching_activity*

```
[-objects object_list]
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
[-sci_based type]
[-apply]
[-verbose]
[-quiet]
[-output file_name]
```

Data Types

```
object_list          list
mode_list            list
corner_list          list
scenario_list        list
type                 string
file_name            string
```

Feedback

Arguments

`-objects` *`object_list`*

List of objects (pins, ports, nets, cells) for which to report the activity influencing essential points. For a net, the tool considers any essential point in its fanin. For pins or ports, the tool considers any essential point in the fanin; if the pin or port happens to be an essential point, it reports and applies activity for the pin/port itself. For cells, the tool considers any essential point that is in the fanin of its input pins.

`-modes` *`mode_list`*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes occurs.

`-corners` *`corner_list`*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering occurs on corners.

`-scenarios` *`scenario_list`*

Specifies the scenarios to be considered. If this option is not specified, then the considers only those scenarios that contain the modes and corners specified through *-modes* and *-corners* options. The command output is generated separately for each scenario. If none of the *-modes*, *-corners*, or *-scenarios* options is specified, the command reports the current scenario in the design.

`-sci_based` *`type`*

Specifies whether to report or apply activity on any essential point based on the number of special control inputs it influences. The *type* specified can take one of the following three values: *sci*, *non_sci*, and *all*. If type is *sci*, the activity for any essential point is reported and applied based on the number of SCIs (Special Control Inputs) in its fanout. If there is no SCI in the fanout of an essential point, the tool does not report for the point. For the *non_sci* type, the default activity value is reported and applied on all essential points that do not have any SCIs in their fanout. If the type is *all*, the tool reports and applies all the essential points. If this option is not specified, the default behavior corresponds to *all*.

`-apply`

Applies the proposed switching activity annotation on the drivers of the special control input pins. The activity type for points where activity has been applied is *inferred*.

Feedback

`-verbose`

Reports detailed information for each special control input in the fanout of an object.

`-quiet`

Suppresses the output report of the command. If either *-apply* or *-output* option has been specified, activity will still be applied/written out to a file accordingly.

`-output` *`file_name`*

Creates a file with *set_switching_activity* commands that can be used to apply the activity on all or specified essential points.

Description

This command infers the switching activity on the drivers of the Special Control Input pins (SCIs) in the design. These pins can be clock pins, set pins, reset pins, scan enables, isolation cell control pins, power switch control pins, and so on. The switching activity includes toggle rate and static probability on the drivers of these pins.

The *-objects* option can be used to filter the essential points for reporting and applying the activity. To filter for scenarios, the *-modes*, *-corners*, and *-scenarios* options can be used. To determine whether to report and apply activity for essential points with zero or nonzero SCI count, the *-sci_based* option can be used. If the *-sci_based* option is not specified, all essential points are considered for reporting and applying. Use the *-apply* option to apply the inferred switching activity values on the drivers of the pins. For a detailed report, the *-verbose* option can be used. The *-quiet* option can be used to suppress the output report. The *-output* option creates a file with *set_switching_activity* commands that can be used to annotate the inferred activity later.

Examples

The following example shows the report generated by the *infer_switching_activity* command.

```
prompt> infer_switching_activity
Information: Activity for scenario scenario1 was cached, no propagation
 required. (POW-005)

init_hier_optimization

Perform the initial setups needed for THO.

Syntax

int *init_hier_optimization*

```
[-flow pre_route | post_route ]
[-detached_hier_route_eco]
```

Arguments

`-flow pre_route | post_route`

Specifies the stage of the flow in which the THO operations shall be performed. You can select any of pre_route or post_route. Pre-route indicates operations during *compile_fusion -final_opto* and *place_opt -final_opto*. Post-route indicates operations during *route_opt* and *hyper_route_opt*. Default value of this option is pre_route.

`-detached_hier_route_eco`

Allows the post-route THO flow to perform subblock eco routing out- side of the mega command using the stand-alone command hier_route_eco. This option is only allowed in combination with the post_route flow, and is only supported for route_opt. The option is ignored when using hyper_route_opt.

Description

The *init_hier_optimization* command performs the initial setups needed for THO. The operations performed include the initializations required for THO and promotion of dont_touch and size_only constraints from the sub-blocks that are open for optimization.

See Also

- commit_hier_optimization

- hier_route_eco

---

initialize_floorplan

Creates an initial floorplan with a die boundary, core, site array (or rows), and wire tracks. Support is provided for a die boundary that is coincident with the core, or a rectilinear core with rectangular die boundary.

Syntax

```
int initialize_floorplan
[-control_type core | die]
[-shape R | L | T | U]
[-side_length {side_a side_b [side_c side_d side_e side_f]}]
[-side_ratio {side_a side_b [side_c side_d side_e side_f]}]
[-core_utilization ratio]
[-keep_boundary]
[-boundary { {x y} {x y} {x y} {x y} ... } ]
[-orientation N | W | S | E]
[-coincident_boundary true | false]
[-core_offset  { value | X_Offset Y_Offset | side_1 ... side_N}]
[-row_core_ratio ratio]
[-flip_first_row true | false]
[-keep_pg_route]
[-keep_detail_route]
[-keep_placement {io macro block std_cell physical_only all} ]
[-keep_objects object_name_or_collection]
[-keep_object_types {placement_blockage routing_blockage move_bound}]
[-keep_all]
[-honor_pad_limit]
[-site_def site_def_name]
[-use_site_row]
[-origin_offset {x, y}]
[-row_pattern row_pattern_name]
[-macro_utilization ratio]
[-create_backside_ipc_ring]
[-ring_layer ring_layer_name]
[-ring_width value]
[-ring_owner ring_owner_name]
[-tag tag_name]
```

Data Types

ratio	float
x	float
y	float
value	float
X_Offset	float
Y_Offset	float

Feedback

```
side_*                      float
object_name_or_collection   string or collection
site_def_name               string
row_pattern_name           string
ring_layer_name             string
ring_owner_name             string
tag_name                   string
```

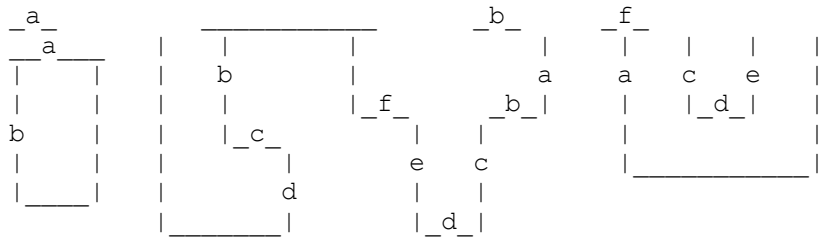
Arguments

`-control_type core | die`

Specifies whether the side_length and side_ratio options apply to the core or the die boundary. If set to die, then the dimensions are applied to the die boundary and the core_offset values are subtracted from the dimensions to determine the core boundary. If set to core (default), the dimensions are applied to the core boundary and the core_offset values are added to the dimensions to determine the final die boundary. By default, the control type is core.

`-shape R | L | T | U`

Specifies the shape to be used by the command. If the control_type is die, this option applies to the die boundary shape. The argument to this option specifies a template shape used to determine the cell boundary and core shape of the rectilinear block. The following diagram shows the definition of the edges and the orientation of the R-, L-, T-, and U- rectilinear blocks. By default, the core shape is R (rectangular).



`-side_length { side_a side_b [side_c side_d side_e side_f]}`

Specifies the side lengths for the edges of the floorplan. If the control_type is die, the side lengths apply to the die boundary. Each dimension in the list represents the length of the edge. If you provide more values than required to describe the specified shape, the extra values are ignored. If you do not provide all of the values required to describe the specified shape, the tool issues an error message. There are only two dimensions for *-shape R*: width and height. This option is mutually exclusive with the *-side_ratio* option.

`-side_ratio { side_a side_b [side_c side_d side_e side_f]}`

Specifies the relative proportion of the floorplan edges in relation to each other. If the control_type is die, the side rations apply to the boundary side settings.

Each dimension in the list represents the relative proportion of the dimension of the edge to the sum of all the dimensions listed. For example, if the list of dimensions of an L-shaped block is {1 2 1 1}, the tool calculates the dimension of side a, c, or d (where the value is 1) as 20 percent (1/1+2+1+1) of the sum of the dimensions listed. The dimension of side b is 40 percent of the summation, and so on.

`-core_utilization` *`ratio`*

Specifies the utilization of the core area. The utilization is the total area of the core occupied by all standard cells and macro cells divided by the total core area. You can specify a value between 0 and 1. The cell area includes all standard and macro cells. For example, a core utilization of 0.8 specifies that 80 percent of the core area is used for cell placement at this stage. The tool might later add more cell area, the remaining area is available for routing. By default, the core utilization is 0.7.

`-macro_utilization` *`ratio`*

Specifies the utilization of the macro cells. The default is same as core_utilization value: range 0 to 1.

`-keep_boundary`

Uses the existing die boundary. If this option is specified and the core-based constraints result in a core that is too large to fit in the existing die boundary, the command issues an error message. Default is not specified.

`-boundary { {`*`x y`*`} {`*`x y`*`} {`*`x y`*`} {`*`x y`*`} ... }`

Specifies the shape to be used by the command. If the control_type is core, then the boundary defines the core area and the core_offsets should be added to create the die boundary. If control_type is die, then the core_offset is subtracted from the die boundary to create the core boundary.

`-orientation N | W | S | E`

Specifies one of four possible orientations for the specified rectilinear shape. The tool repositions the block to the specified orientation by rotating it in a clockwise direction. For *-shape R*, the orientation is always N.

`-coincident_boundary true | false`

Specifies whether the die boundary follows the shape of the core. If true, the die boundary assumes the same shape as the core and requires a *-core_offset* setting with the same number of sides as the core. If false, the die boundary is rectangular and the *-core_offset* option requires only four values. When the die boundary is rectangular it is created with *-core_offset* values such that the offset value is honored to the closest core edge on a per side basis. In this case, the bounding box of the die boundary is the minimum size that meets all four *-core_offset* values. By default, this option is true.

Feedback

`-core_offset { value | X_Offset Y_Offset | side_1 ... side_N}`

Specifies the distance between the side of the core and the side of the die boundary. If only one value is specified, the value is used for all sides. If two values are specified, the first value is the distance in the horizontal direction from the die boundary vertical edges and the second value is the distance in the vertical direction from the die boundary horizontal edges. Side numbers are based on the standard rectilinear numbering and do not correlate to the side_a, side_b, and so on, numbering scheme used to define the size of each edge. By default, the core offset equals to the minimum I/O cell height. If there are no I/O cells, the core offset is 0.

`-row_core_ratio ratio`

Specifies the amount of channel area between cell rows in the core area to reserve for routing. The *ratio* is a number between 0 and 1.0. A smaller row-to-core ratio creates more space for routing channels. A value of 1.0 creates no routing channel space. By default, the ratio is 1.0. Note that this ratio should be equal to or greater than the core utilization value.

`-flip_first_row true | false`

Specifies whether the command flips the first row at the bottom of the core area for horizontally placed cell rows, or flips the leftmost row for vertically placed cell rows. By default, this option is true.

`-keep_pg_route`

Specifies that the command keeps the PG routes and does not delete them. By default, the command delete all existing routes.

`-keep_detail_route`

Specifies that the command keeps all the routes except PG routes and does not delete them. By default, the command delete all existing routes.

`-keep_placement {io macro block std_cell physical_only all}`

Specifies that the command keeps the placement of specified object types. The valid value for this options are: *io, macro, block, std_cell, physical_only, all*.

io means objects with design type "*flip_chip_driver, flip_chip_pad, corner, pad, pad_spacer*";

macro means objects with design type "*macro, analog, abstract*";

block means objects with design type "*module, black_box*";

physical_only means objects with design type "*feedthrough, fill*";

std_cell means objects with design type "*lib_cell, cover, diode, end_cap, well_tap, filler*";

Feedback

all means all objects with design type list above.

`-keep_objects` *`object_name_or_collection`*

Specifies the objects to be kept. Currently supported objects are cells and nets. Specify the objects either by using an object access command, such as *get_cells* or *get_nets*, or by specifying object name patterns in a Tcl list.

`-keep_object_types {placement_blockage routing_blockage move_bound}`

Specifies the object type to be kept. Currently supported object types are placement_blockage, routing_blockage and move_bound.

`-keep_all`

Specifies this option to keep macro, std_cell, I/O, physical_only, block, blockage, detail_route and pg_route.

`-honor_pad_limit`

Adjusts the core and die size to honor pad-limited designs. If this option is not specified, the core area is created based on the default core utilization ratio 0.7.

The option can be used only for rectangular floorplans, not for L, T, or U shapes.

The assumption for the command option is that the pad-type cells ()I/O pads or flip chip drivers) are placed around the design boundary.

`-site_def` *`site_def_name`*

Specifies the site def to be used in floorplan when there are multiple site defs in the technology file. The default is to use default site def. If there is no default site def, the command uses the site def with the smallest site width.

`-use_site_row`

By default, the *initialize_floorplan* command creates siteArray objects. This option forces the command to create siteRow rather than siteArray.

`-origin_offset {x y}`

Specifies the location of the lower-left corner of the die boundary bounding box with respect to the origin of the block.

`-row_pattern` *`row_pattern_name`*

Specifies the name of row_pattern to be used for floorplan when there are row patterns specification in the physical rule section of technology file.

`-create_backside_ipc_ring`

Specifies that the command creates the ipc boundary ring. By default, the command does not create the ipc boundary ring.

Feedback

`-ring_layer` *`ring_layer_name`*

Specifies ring layer to be used for creating the ipc boundary ring. The default is to use default bmp_ipc layer when the technology node is p1278.

`-ring_width` *`value`*

Specifies the value of the ring width for creating the ipc boundary ring. The default value is 80nm when the technology node is p1278.

`-ring_owner` *`ring_layer_name`*

Specifies the ring owner attached to the ipc boundary ring. The default is to use default VSS when the technology node is p1278.

`-tag` *`tag_name`*

Specifies the tag for created ring shapes. This option must be specified with *-create_backside_ipc_ring*.

Description

Creates a floorplan with a boundary, core, site array (or rows), and wire tracks. Before executing this command, you must open a physical design by using the *open_block* command, or create a design with the *read_verilog* or *read_verilog_outline* commands.

Examples

The following example creates a rectangular core and die boundary with a core utilization of 80 percent and a core offset of 1000 um for each side.

```
prompt> initialize_floorplan -core_utilization 0.8 \\
        -core_offset {1000 1000 1000 1000}
```

The following example creates a rectangular die boundary and a T-shaped rectilinear core with the specified side dimensions for the core and a core_offset of 100 um for each side.

```
prompt> initialize_floorplan -control_type core -shape T \\
        -side_length {1000 750 1500 750 1750 750} \\
        -coincident_boundary false \\
        -core_offset {100}
```

The following example creates a T-shaped rectilinear core and die boundary with the specified side dimensions for the core and a core offset of 100 um for each side.

```
prompt> initialize_floorplan -shape T \\
        -side_length {1000 750 2500 500 3000 500} \\
        -core_offset {100 100 100 100 100 100 100 100}
```

The following example creates a T-shaped rectilinear core and die boundary with the specified side ratios for the core and a core offset of 10 um for each side and a core utilization of 80 percent.

Feedback

```
prompt> initialize_floorplan -core_utilization 0.8 \\
        -shape T \\
        -side_ratio {2 1 3 1 3 1} \\
        -core_offset {100 100 100 100 100 100 100 100}
```

---

insert_buffer

Adds buffer cells on the nets that are connected to the specified pins.

Syntax

collection *insert_buffer*

```
[-new_net_names new_net_names]
[-new_cell_names new_cell_names]
[-inverter_pair]
[-no_of_cells number]
object_list
[-lib_cell buffer_lib_cell] | [buffer_lib_cell]
[-snap]
[-respect_voltage_areas]
```

Data Types

new_net_names	list
new_cell_names	list
number	integer
object_list	list
buffer_lib_cell	collection

Arguments

`-new_net_names` *new_net_names*

Specifies the names of the new nets to add. You must specify one net name per buffer when adding buffers, and two net names per inverter pair when adding inverter pairs. If the specified net name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the net name.

Optionally, if you specify only the common base name, the tool generates new net names by adding unique numeric suffixes to the common base name. The specified names can be any valid net names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical

Feedback

separators. They must be unique in the current context, as specified by the current instance. By default, the command uses the base name eco_net.

`-new_cell_names` *new_cell_names*

Specifies the names of the new cells to be added. You must specify one cell name per buffer when adding buffers, and two cell names per inverter pair when adding inverter pairs. If the specified cell name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the cell name.

Optionally, if you specify only the common base name, the tool generates new cell names by adding unique numeric suffixes to the common base name. These names can be any valid cell names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance.

By default, the command uses *eco_cell* as the common base name.

`-inverter_pair`

Adds inverter pairs instead of buffer cells. If you specify this option, you must supply a library cell that has an inverting output. You can use this option when the specified library cell or buffer has both inverting and noninverting outputs.

`-no_of_cells` *number*

Specifies the number of buffer cells or inverter pairs to be inserted per net. The inserted repeaters are connected back-to-back in series. By default, the command inserts a single buffer cell or inverter pair per net.

object_list

Specifies a list of nets, pins, or ports that must be buffered. The new buffer cells or inverter pairs are placed close to the specified pins or ports if their cells are placed.

If you specify a net, the tool connects the buffers or inverter pairs such that a new buffer cell is the new load of the original net.

If you specify pins, the tool groups all of the specified pins based on the nets to which they are connected. When the grouped pins are load pins, the tool adds the buffers so that the new buffer cells can drive them. When the grouped pins are driver pins, the tool connects the new buffer cells so that they become the load of the specified driver pin.

`-lib_cell` *buffer_lib_cell*

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. This is a required option. This option is mutually exclusive with *buffer_lib_cell*.

Feedback

If the library cell has both inverting and noninverting outputs, that is, it can act both as buffer and inverter, the *-inverter_pair* option controls which output is used. If the library cell has multiple outputs, the command uses the first noninverting or inverting output.

buffer_lib_cell

This positional option is exactly equivalent to -lib_cell. And it is mutually exclusive with *-lib_cell*.

-snap

Put the new buffer cells next to the target cell, then snap the buffer cells to the closest site, and flip the buffer cells when needed.

If you specify a net or a driver pin with this option, the new buffer cells are placed next to the target cell of driver pin if the target cell are placed.

If you specify a load pin with this option, the new buffer cells are placed next to the target cell of load pin if the target cell are placed.

If you specify a list of load pins on the same net with this option, the new buffer cells are placed in the center of all load pins if the target cell are placed.

This option is mutually exclusive with the *-respect_voltage_areas* option.

-respect_voltage_areas

Inserts buffers within the hierarchy of the voltage area such that the buffer is physically in the layout. This option is mutually exclusive with the *-snap* option.

Description

This command adds buffers or inverter pairs at one or more specified pins or ports. A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

Like all other netlist editing commands, the command arguments to *insert_buffer* must be valid for the command to run successfully. If the command succeeds, the result is a collection of the newly-added cells. If the command fails, the command returns an empty collection or an empty string and does not change the netlist.

By default, each newly-created cell has a name beginning with the eco_cell string and ending with a unique numeric suffix. Each newly-created net has a name beginning with the eco_net string and ending with a unique numeric suffix. To override the automatic name generation by the tool, use the *-new_net_names* and *-new_cell_names* options.

You can mimic buffer addition by using other commands, such as *create_cell*, *create_net*, *disconnect_net*, and *connect_net*. The *insert_buffer* command provides a more efficient and safe way to add buffers.

Feedback

This command support editing a Verilog module in the module aspect, through *edit_module*.

This command checks if the block is editable before adding buffer cells.

This command honors the *design.eco_freeze_silicon_mode* application option. When this application option is *true*, the *is_fs_eco_add* attribute of the added buffers is set to *true*.

This command is exactly equivalent to *add_buffer*.

The *insert_buffer* command uses the following basic rules to check its arguments for validity:

- The pin or port must be in scope; that is, at or below the current instance. For a description of special scoping rules, see the "Buffering Inside Boundary Pins" section.
- The pin or port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The net cannot be either a PG net or a tie net.
- The specified library cell cannot be sequential.
- The specified library cell must be a buffer, as previously defined.
- The *number* argument of the *-no_of_cells* option must be a positive, nonzero integer.
- The library cell must have an inverting output, when you use the *-inverter_pair* option. The command uses the first inverting output and adds two cells so that it preserves the logic of the path.

Adding and Connecting the New Buffer

The following figure shows an example network that is used to describe the rules used by the *insert_buffer* command to connect the new buffer or inverter pair:

```
+--- e3/A
                        |
e1/Z ---- old_net -----+--- e4/A
                        |
                        +--- e5/A
```

If the specified pin is a load, the load is first disconnected from its old net and then connected to the new net, as shown in the following figure:

```
+--- eco_cell --- eco_net --- e3/A
                        |
e1/Z ---- old_net -----+--- e4/A
                        |
                        +--- e5/A
```

Feedback

If the specified pin is a driver, all loads on that net are disconnected from the old net and are connected to the new net, as shown in the following figure:

```
+--- e3/A
                                                |
e1/Z --- old_net --- eco_cell --- eco_net -+--- e4/A
                                                |
                                                +--- e5/A
```

If you specify a list of load pins on the same net, these load pins are grouped and the new net drives them, as shown in the following figure:

```
+--- e3/A
                    |
e1/Z --- old_net -+- eco_cell --- eco_net -+--- e4/A
                                                |
                                                +--- e5/A
```

Note that the tool cannot buffer a net driven by multiple drivers.

Buffering Inside Boundary Pins

When you use this command to add a buffer at a pin on the boundary of a hierarchical block, the command adds the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To add the buffer inside the hierarchical block, set the scope to that block by using the *current_instance* command, and then run the *insert_buffer* command. The tool adds the buffer within the block to which the *current_instance* is set.

Don't touch support for nets

When application option *eco.insert_buffer.honor_dont_touch* is set to true, nets with dont_touch attribute are skipped.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example specifies a library cell that is not a buffer. The command fails and generates an error message.

```
prompt> insert_buffer e1/Z -lib_cell class/AN2P
Information: Buffering net old_net. (HFS-701)
Error: library cell 'AN2P' is not a buffer or an inverter. (ECOUI-010)
```

The following example specifies a buffer for the library cell:

```
prompt> insert_buffer e1/Z -lib_cell class/B1I
{eco_cell}
```

Feedback

The following example specifies an inverter for the library cell. The command succeeds and creates the new cells named *eco_cell* and *eco_cell_1*. The new nets are named *eco_net* and *eco_net_1*. The *report_cells* command displays the connections for cell e3.

```
prompt> insert_buffer e3/A -lib_cell class/IV -inverter_pair
{eco_cell eco_cell_1}

prompt> report_cells -connections e3
****************************************
Report : cell
 -connections
****************************************

insert_dft

Inserts DFT structures in the current design

Syntax

```
status insert_dft
```

Arguments

This command has no arguments.

Description

insert_dft performs DFT structures insertion and routing. To insert scan compressor IP, clock controller or wrapper cells, use the applicable DFT configuration commands for that DFT logic type before running insert_dft.

Examples

prompt> insert_dft

insert_power_tap_cells

This command inserts special purpose tap cells with a user speficied interval on strong and weak shields shielding clock tree nets.

Syntax

status *insert_power_tap_cells*

```
[-lib_cells library cells to use as special purpose power tap cells. This
 is required option.]
[-nets lock nets whose shield shapes are selected for tap cell insertion]
[-shapes hielding shapes to consider for power tap insertion]
[-tap_frequency distance between two consecutive tapcells. This is
 required option for strong shield support. It is not needed for strong
 shield support]
[-distance_threshold max allowance for tap cell insertion in
 perpendicular direction from shield shape for weak shield support. It is
 not needed for strong shield support.]
[-via_ladder_list Ordered list of via ladder template names and metal
 layer.]
[-boundary bounding box where taps would be inserted.]
```

Data Types

lib_cells	collection
nets	collection
shapes	list or collection
tap_frequency	float
threshold distance	float
via_ladder_list	collection
boundary	bbox

Arguments

`-lib_cells` *library cells to use*

Specifies the special purpose library reference cell to be used as a tap cell. We need to specify this as this is a required option.

`-nets lock nets from which the shield shapes are selected`

Specifies clock nets whose shield shpapes to be inserted with tap cells.

`-shapes nly shield shapes to consider for power taps insertion`

Specifies a list of shield shapes for power tap cells insertion.

Feedback

`-tap_frequency` *`distance between two consecutive tapcells`*

Specifies the distance between two consecutive tap cells in a row. This is also required option for strong shield support.

`-threshold_distance` *`max perpendicular distance from shield shape`*

Tap cells are by default inserted on shielding shapes. The threshold distance helps to specify region around the shield shape, tap cell can be inserted any where within that region in orthogonal direction. This is required option for weak shield support and not needed for strong shield support.

`-via_ladder_list` *`Ordered list of via ladder template names`*

The via ladder specification tells how tap cells would be connected through the metal layers using via descriptions. This is specified as ordered list of strings with syntax "<metal layer>:<via rule>"

`-boundary` *`bounding box where taps would be inserted`*

user specifies bounding box where taps will be inserted during eco mode

Description

The *insert_power_tap_cells* command adds special purpose power tap cells to clock shielding. This command automates additon of tap cells to clock shield based on the user provided params. This is primarily used for high-speed clock network where backside metal PG is used for deliver power to std cells. This is done via special cells that will have both frontside/backside metal power pins which are connected internally. If cell cannot be placed for any reason to meet the user specification then relevant error or warning is thrown for specifific instance. For weak shield support, this utility command sprinkles one tap around each shield component. It searches existence of vss pin before sprinkling new one, if already found existing, that will be used for association and routing.

Examples

In the following example, power tap cells are inserted on the strong shiled shapes of a given *nets* at specified *tap_frequency*.

```
prompt> insert_power_tap_cell -lib_cells LIBCELL -nets netName
 -tap_frequency 10
```

In the following example, tap cells are inserted around the given shield shapes.

```
prompt> insert_power_tap_cells -lib_cells [get_lib_cells */INVGX8M]
 -tap_frequency 10 -shapes { PATH_48_12 PATH_48_13 }
```

In the following example, tap cells are inserted around the weak shield shapes of a given net within specified istance_threshold from shield shape.

```
prompt> insert_power_tap_cell -lib_cells LIBCELL -nets netName
 -distance_threshold 2
```

Feedback

In the following example, tap cells are inserted on the shield shapes of a given net with specified ia_ladder_list.

```
prompt> insert_power_tap_cell -lib_cells LIBCELL
 -nets "netName" -tap_frequency 10 -via_ladder_list
 m1:rule1,m10:VL_shield_m1_to_m10,m9:VL_shield_m1_to_m9
```

---

insert_redundant_trees

Reduces common path sharing of split pins on safety_register_groups and safety_core_groups.

Syntax

string *insert_redundant_trees*

```
[-safety_register_groups safety_register_groups]
[-safety_core_groups safety_core_groups]
[-buffer_lib_cell lib_cell]
[-inverter_lib_cell lib_cell]
[-pin_types pin_type_list]
[-pins pins]
[-suppress_initial_buffering]
```

Data Types

safety_register_groups	list
safety_core_groups	list
lib_cell	string
pin_type_list	list
pins	collection

Arguments

`-safety_register_groups` *safety_register_groups*

Operates on split pins of the given safety register group objects. This option is mutually exclusive with -safety_core_groups.

`-safety_core_groups` *safety_core_groups*

Operates on split pins of the given safety core group objects. This option is mutually exclusive with -safety_register_groups.

Feedback

`-buffer_lib_cell` *`lib_cell`*

Provides the library cell that must be used when creating a guide buffer.

`-inverter_lib_cell` *`lib_cell`*

Provides the library cell that must be used when creating a guide inverter.

`-pin_types` *`pin_type_list`*

Operates only on split pins that match the given pin types. Allowed values are *clock*, *reset* and *scan*. A list of one or more such types can be specified.

`-pins` *`pins`*

Operates only on split pins that match the given pins by port name.

`-suppress_initial_buffering`

Operates on a set of split pins. The first non repeater drivers found via back tracing from these split pins are considered for reducing common paths. Part of the modification of the buffer tree is to add a high effort net weight on the driver output net. Before doing so, the net is buffered by a guide buffer to avoid pulling the loads close to the driver. By setting this option, this guide buffer is not added.

Description

This command operates on the buffer trees that drives a pin of a split pin group, and adds constraints to reduce common paths shared by these split pins. A split pin group is a group of split pins with equal port_names belonging to objects of the same redundancy group (either a safety_register_group or a safety_core_group).

Drivers of the split pins are identified using back-tracing from those split pins until a block port, or a non buffer leaf cell, or a hierarchical pin of a frozen hierarchy is found. If a driver caters for multiple split pins of one split pin group, the following measures are taken to reduce common paths shared by these pins.

A guide buffer is injected behind the driver. The driver output net is given a high effort net weight. Back-tracing reveals which cones of the buffer tree uniquely drive one split pin. Cones might share a common path to the driver and if that happens, one of the two is reconnected to the output of a guide buffer or invert which is added to driver's output net.

After running the command, none of the split pins in a split pin group have a common path between their drivers.

Examples

The following is an example of running *insert_redundant_trees*:

```
prompt> insert_redundant_trees -buffer_lib_cell BUFX4MTH -pin_types
 {clock reset} -safety_register_groups *
```

Feedback

```
Information: Working on 12 split pins, driven by 4 unique drivers. The
 split pins form 4 groups which require splitting. The design contains 1
 safety register groups and 3 safety core groups. (SRM-013)
Information: Added 3 guide buffers and 0 guide inverters. The design
 contains 12 guide buffers and 0 guide inverters in total. (SRM-014)
```

---

insert_safety_core_boundary_protection

Adds protection to a safety core avoiding transit cells.

Syntax

string *insert_safety_core_boundary_protection*

```
[-safety_core_groups safety_core_groups]
[-buffer_lib_cell lib_cell]
[-maximum_fanout count]
[-verbose]
```

Data Types

```
safety_core_groups    list
```

Arguments

`-safety_core_groups safety_core_groups`

Operates on safety cores of given safety core group objects. This command operates on all the safety_core_groups in the current block, when this option is left unspecified.

Description

Transit cells are buffers or inverters belonging to a safety core, which are on boundary crossing nets between internal cells (the other leaf cells of the safety core) and cells not belonging to the safety core. Counter to the internal cells, the transit cells have more

Feedback

freedom as they are not physically constrained by the legalization bound of the safety core.

This command can be run if you do not want to give the tool this freedom. The command adds a freeze_ports constraint (reason: safety) on the top-most hierarchical cells making up the safety cores and adds a dont_touch constraint (reason: safety) on the boundary crossing nets and marks them with an attribute called stop_transit_cell.

As an effect, all cells of the safety core are considered internal and consequently need to be placed within the legalization bound of the safety core.

-maximum_fanout *count*

Specifies the largest allowable boundary net fanout that requires no buffer.

-buffer_lib_cell *lib_cell*

Provides the library cell that must be used when creating a buffer.

-verbose

Report additional information.

Examples

The following is an example of running *insert_safety_core_boundary_protection*:

```
prompt> insert_safety_core_boundary_protection -safety_core_groups *
```

---

insert_topology_repeater_connections

This command allows user to update a netlist with topology repeater connections at an earlier stage in the TIP flow, that is, after topology repeater optimization, but before characterization of a topology plan.

Syntax

insert_topology_repeater_connections

```
[topology_plan_list]
[-buffer_lib_cell cell_name]
[-register_lib_cell cell_name]
```

Feedback

```
   [-type sequential | repeater]
   [-cell_prefix prefix]
   [-net_prefix prefix]
   [-tcl_function func_name]
```

Data Types

```
topology_plan_list  collection
cell_name      string
bit_num        integer
func_name      string
refix          string
```

Arguments

topology_plan_list

Specifies a list of topology plans to update the topology repeater connections. If omitted, the command applies to all topology plans defined in the current block.

`-buffer_lib_cell` *cell_name*

Specifies lib cell name for buffer insertion. If omitted, the tool uses the cell name from the topology plans NER settings (buffer NER attribute).

`-register_lib_cell` *cell_name*

Specifies lib cell name for register insertion. If omitted, the tool uses the cell name from the topology plans NER settings (register NER attribute).

`-type sequential | repeater`

Specifies which topology repeater type to process. If omitted, the command examines all the topology repeaters that are in the topology plans.

`-cell_prefix` *prefix*

Specifies the prefix to be used for new repeater cells that are inserted in the netlist. By default, the command uses topology edge fullname as the prefix.

`-net_prefix` *prefix*

Specifies the prefix to be used for new nets that are created when repeater cells are inserted in the netlist. By default, the command uses topology edge fullname as the prefix.

`-tcl_function` *func_name*

Specifies existing tcl function to generate customize new cell names. Function takes three arguments (repeaterName netName bit) and returns string value to use as new cell name.

Feedback

Description

The command *insert_topology_repeater_connections* takes existing topology repeaters without cells association and adds new repeater cell connections into netlist, and assigns them back to topology repeaters. The connections are created in the proper block (or top level) to maintain physical hierarchy.

By default, each newly added repeater cell/net has a name beginning with the topology edge fullname prefix and ending with a numeric suffix. To override the automatic name generated by the tool, use the *-cell_prefix*, *-tcl_function* and the *-net_prefix* options.

The tool automatically adds supernet exceptions for any new registers.

The command returns 1 if successful; 0 otherwise.

Examples

The following example updates repeater connections (registers only) for the current topology plan.

```
prompt> insert_topology_repeater_connections [current_topology_plan]
 -type sequential
```

---

insert_via_ladders

Inserts via ladders on pins with via ladder constraints.

Syntax

status *insert_via_ladders*

```
[-nets {collection_of_nets}]
[-pins {collection_of_pins}]
```

Data Types

```
mode                  string
{collection_of_nets}  collection
{collection_of_pins}  collection
number_of_levels      int
distance              float
```

Feedback

Arguments

`-nets {collection_of_nets}`

Specifies the nets on which to insert via ladders. A via ladder is inserted on pins with via ladder constraints only when the pin is also on one of the specified nets.

If you do not specify this option, via ladders are inserted on any pin with a via ladder constraint.

`-pins {collection_of_pins}`

Specifies the pins on which to insert via ladders.

Description

The *insert_via_ladders* command inserts via ladders on pins with via ladder constraints.

The command is controlled by route.auto_via_ladder.* app option settings.

Via ladder rules are specified in a ViaRule section of the technology file or by using the *create_via_rule* command.

Via ladder constraints are assigned to pins by using the *set_via_ladder_constraints* or *set_via_ladder_rules* command.

Examples

The following example inserts a via ladder on any pin with a via ladder constraint. Non-fixed detail routing shapes are ignored. Patching is allowed. Extra information is printed for any via ladder insertion failure.

set_app_options -list {route.auto_via_ladder.ignore_routing_shape_drcs true}
set_app_options -list {route.auto_via_ladder.user_debug true} set_app_options -list {route.auto_via_ladder.allow_patching true}

```
insert_via_ladders
```

Feedback

is_false

Tests the value of a specified variable, and returns 1 if the value is 0 or the case-insensitive string *false*; returns 0 if the value is 1 or the case-insensitive string *true*.

Syntax

```
status is_false
value
```

Data Types

```
value      string
```

Arguments

value

Specifies the name of the variable whose value is to be tested.

Description

This command tests the value of a specified variable, and returns 1 if the value is either 0 or the case-insensitive string *false*. The command returns 0 if the value is either 1 or the case-insensitive string *true*. Any value other than 1, 0, *true*, or *false* generates a Tcl error message.

The *is_false* command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings *true* or *false*. When such variables are set to *true* or *false*, they cannot be tested in the negative in an *if* statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x FALSE
if { !$x } {
  set y TRUE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, *is_false* allows you to test both conditions safely.

Examples

The following example shows the use of the *is_false* command:

```
prompt> set x TRUE
TRUE

prompt> if { ![is_false $x] } {
?         set y TRUE
?       }
```

Feedback

```
TRUE

prompt>
```

See Also

- is_true

---

is_true

Tests the value of a specified variable, and returns 1 if the value is 1 or the case-insensitive string *true*; returns 0 if the value is 0 or the case-insensitive string *false*.

Syntax

```
status is_true
value
```

Data Types

```
value      string
```

Arguments

value

Specifies the name of the variable whose value is to be tested.

Description

This command tests the value of a specified variable, and returns 1 if the value is either 1 or the case-insensitive string *true*. The command returns 0 if the value is either 0 or the case-insensitive string *false*. Any value other than 1, 0, *true*, or *false* generates a Tcl error message.

The *is_true* command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings *true* or *false*. When such variables are set to *true* or *false*, they cannot be tested in the negative in an *if* statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x TRUE
if { !$x } {
  set y FALSE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!". So, although you can test the positive condition, *is_true* allows you to test both conditions safely.

Feedback

Examples

The following example shows the use of the *is_true* command:

```
prompt> set x FALSE
FALSE

prompt> if { ![is_true $x] } {
?         set y FALSE
?       }

FALSE

prompt>
```

I

lc_sh

Run LC commands with the background lc_shell session

Arguments

Args are lc_shell commands and arguments to be executed in lc_shell session. Args within braces ({})can prevent the tcl substitution ($) and execution ([]) If more than one commands to be executed in one line, each command must be separated by semicolon (;). Remember to use braces, otherwise we need back slash for the semicolon (\;) Args can be “source lc.tcl” to source a tcl script file This argument can be "exit" / "quit" to close the current lc_shell session.

Description

Use this command to run LC commands with the background lc_shell session. Start an lc_shell session if no active lc_shell session running in the background.

Examples

The following example run LC commands with background lc_shell session.

```
prompt> lc_sh \\
   read_lib ../test.lib

prompt> lc_sh \\
   exit
```

Feedback

```
prompt> lc_sh \\
   {read_lib ../test.lib; write_lib test -o .../test.db}

prompt> lc_sh \\
   source lc.tcl
```

---

legalize_placement

Executes detailed placement on the current design.

Syntax

status *legalize_placement*

```
[-cells list_of_cells]
[-moveable_distance distance]
[-boundary boundary_spec]
[-incremental]
[-post_route]
```

Data Types

```
list_of_cells  list or collection
distance       float
boundary_spec   float
```

Arguments

`-cells list_of_cells`

Specifies the cells to be legalized. You must set the *place.legalize.legalize_only_selected_cells* application option to true or use the *place_eco_cells -cells -legalize_only* command before the *legalize_placement -cells* command. Without specifying the *-moveable_distance* option, only those cells are legalized and all other cells not in the list remain unchanged, no matter they are legal or not.

`-moveable_distance distance`

By default, the value of movable distance is 0.0. That means only the specified cells are legalized. When you specify a movable distance using *-moveable_distance* option, other cells around that target cell become movable during legalization. The size of movable rectangle region based on the given distance is {{llx - moveable_distance lly - moveable_distance} {urx + moveable_distance ury + moveable_distance}}. All the cells inside that rectangle

region are legalized and movable while other cells that are not in the region remain unchanged during legalization. The movable distance value should be equal or larger than 0.0, and it can be used only with *-cells* option.

`-boundary` *`boundary_spec`*

Instead of specifying a collection of cells, you can use the *-boundary* option to specify a region of cells to legalize without knowing the cell name. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  `{{llx lly} {urx ury}}`

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  `{{x1 y1} {x2 y2} ... {xn yn}}`

  All cells inside the specific region are included and legalized while other cells remain unchanged. *Note*: The *-boundary* option includes cells based on cell's bounding box, not based on cell's boundary bounding box. In certain situations, cell's bounding box might be bigger than cell's boundary bounding box, so ensure the boundary region if it is very close to cells. You must verify the cell's bounding box values and adjust *-boundary* option if needed. You might start the GUI to identify the area, get the coordinate information, and run legalization with the *-boundary* option to only legalize that specific area while other area remain same. This option is similar to using the *-cells* option without the *-moveable_distance* option, but you do not need to know the all cell names. The *-boundary* option is exclusive with the *-cells* or *-moveable_distance* option.

`-incremental`

By using the *-incremental* option, the *legalize_placement* command first tries to find all illegal cells. The API used is same as for the *check_legality* command. After it finds illegal cells, the *legalize_placement* command only legalizes those illegal cells while other legal cells remain the same without any change. Use this option when you do not know which cells are illegal, or you do not want to modify an existing design for those legal cells. When legalizer tries to fix the illegal cells, as legal cells remain at the same location and cannot be moved, it might cause legalizer to move illegal cells to other available locations and cause larger displacement. You can use the *-cells* and *-moveable_distance* options to allow the legalizer to move some cells around those illegal cells to resolve larger displacement if required.

The *-incremental* option is exclusive with *-boundary* option.

Feedback

`-post_route`

Specifies that post route mode are used. Legalizer tries to retain original orientation.

Description

The *legalize_placement* command performs placement on the current design after coarse placement has already been performed. When you run this command, the design must contain a floorplan with a site array specified, and all cells and blockages in the design must have an initial location.

Multicorner-Multimode Support

This command uses information from all active scenarios.

Examples

The following example runs the *legalize_placement* command:

```
prompt> legalize_placement
```

The following command legalizes all BUF* cells in the design

```
prompt> set_app_option -name place.legalize.legalize_only_selected_cells
 -value true
prompt> legalize_placement -cells [get_cells BUF*]
```

or

```
prompt> place_eco_cells -cells -legalize_only
prompt> legalize_placement -cells [get_cells BUF*]
```

The following command legalizes individual cells in the design

```
prompt> set_app_option -name place.legalize.legalize_only_selected_cells
 -value true
 prompt> legalize_placement -cells "cellA cellB cellC"
```

or

```
prompt> place_eco_cells -cells -legalize_only
 prompt> legalize_placement -cells "cellA cellB cellC"
```

The following example legalizes all BUF* cells in the design, and include other cells around each BUF* cells within the specific distance

```
prompt> legalize_placement -cells [get_cells BUF*] -moveable_distance 100

To customize the movable distance value per cell instead of
a global movable distance value, like high density area or critical
 timing area,
you can create a user-defined attribute,
```

Feedback

```
and specify different a movable distance value per cell, as in the
 following example:

prompt> define_user_attribute -type float -classes cell -name
 moveable_distance
prompt> set_attribute -name moveable_distance -value 1 [get_cells A]
prompt> set_attribute -name moveable_distance -value 100 [get_cells B]
prompt> set_attribute -name moveable_distance -value 10000 [get_cells C]
prompt> legalize_placement -cells "A B C" -moveable_distance 500

Cell A uses 1 as its region value, cell B uses 100 as its region value,
and cell C use, 1000 as its region value. For other cells, they use 500
as the region value. The movable distance is considered during
 legalization
only if you also specifies the -cells option.
```

The following command legalizes all cells inside the boundary without knowing their names

```
prompt> legalize_placement -boundary {{100 100} {1500 1500}}
```

---

legalize_rp_groups

Executes detailed placement of relative placement groups in a design.

Syntax

```
status legalize_rp_groups
[rp_groups]
[-legalize_over_rp]
```

Data Types

```
rp_groups           list or collection
```

Arguments

rp_groups

Specifies the relative placement groups for which you want to do detailed placement. If you do not specify this option, the command performs detailed placement on all relative placement groups of current block.

Feedback

`-legalize_over_rp`

Controls the detailed placement of the specified relative placement groups. When this option is set, the cells of the specified relative placement groups can be legalized over the cells of unspecified relative placement groups.

`-prototype`

Enables faster legalization of the RP groups. If you specify this option then RP groups will be legalized much faster compared to when this option is not used. Specifying *-prototype* option disables few advanced rules resulting in faster search of legal location for cells.

Description

The *legalize_rp_groups* command performs placement legalization of relative placement groups in the current block, where coarse placement has already been performed. It is necessary to specify a site array for the floorplan. The legalization of relative placement groups of child blocks can not be done by this command.

Note: After you ran this command, the specified relative placement groups might overlap other unfixed cells. Therefore, you might need to run the *legalize_placement* command. If you do not need to perform detailed placement on the specified relative placement groups again, those relative placement groups can be fixed before you run the *legalize_placement* command. You can unfix them after running the *legalize_placement* command if necessary.

Examples

The following examples show how to use the *legalize_rp_groups* command.

```
prompt> legalize_rp_groups rp_group

prompt> legalize_rp_groups rp_group -legalize_over_rp

prompt> legalize_rp_groups -prototype
```

---

link_block

Resolves block references.

Feedback

Syntax

status *link_block*

```
[-force]
[-rebind | -incremental]
[-verbose]
[block_name]
```

Data Types

```
block_name  string
```

Arguments

`-force`

Forces the block to relink, even if the block is already linked. If this option is not specified, the command does not link a block if it is already linked.

`-rebind`

Rebind all references using the current ref_lib list, view switch list and label switch list. The *-rebind* option is mutually exclusive with the *-incremental* option.

`-incremental`

Update only unresolved references. The *-incremental* option is mutually exclusive with the *-rebind* option.

`-verbose`

Writes out additional debugging messages.

block_name

Specifies the name of the block to be linked. If you do not specify this option, the command links the current block.

Description

This command performs a name-based resolution of block references for the specified *block_name* or for the current block. References are resolved using other modules within this block, top modules of other physical hierarchy blocks, and leaf cells within lib cell libraries.

Libraries specified in the ref_lib list are then searched in order for references to physical hierarchy blocks and lib cells. The ref_lib list uses the *search_path* variable to locate libraries. The ref_lib list is usually set when the library is created with the *create_lib* command, but can be updated with the *set_ref_libs* command.

Physical hierarchy blocks can have multiple block views. The command determines the initial block view to use to resolve a reference based on the view switch list for the

Feedback

current block. If none of the selected views of a block exist, the reference is left unbound. After bound to a particular view, a cell remains bound to that view unless rebound with *link_block -rebind*, *change_view*, or *change_abstract*. Use the *set_view_switch_list* command to set the view switch list for the session, a library, or a block.

Physical hierarchy blocks can also have multiple user-labels. The reference resolves by default to the user-label of the top-level block when label switch list is absent. For example, if the top-level block is created with the "netlist" label or unnamed ("") label, then all physical hierarchy block references are resolved using the respective label. If labels are absent, it remains linked in its previous state. Note that lib-cell references unlike hierarchical blocks, are only available and resolved under the default label. After bound to a particular label, a cell remains bound to that label unless rebound with *link_block -rebind*. Use the *set_label_switch_list* command to set the label switch list for the session, a library, or a block.

Physical hierarchy blocks in a reference library can be linked using that library's ref_lib list by setting the *use_hier_ref_libs* attribute on that library to "true".

Unresolved References If the linker fails to resolve one or more references, it creates an unbound leaf cell for each unresolved reference. To fix the problem, first determine and correct the source of the problem, then relink the block using the *link_block* command with the *-force* option. Failures are typically caused by missing libraries or blocks, an incorrectly specified ref_lib list, an incorrectly specified view switch list, label switch list or an incomplete *search_path* variable.

If you can resolve the references by changing the ref_lib list, view switch list, label switch list or *search_path* variable, you must relink the block with *link_block -rebind -force*.

You can limit the detailed reporting for unresolved references by setting the *link.reference_limit* application option. After this limit has been reached, the command reports only a summary of the number of additional unresolved references. Change *link.reference_limit* application option with the *set_app_options* command. Information on *link_block* application options can be found in the *link_options* manual page.

Link Errors Mismatched port references to a lib cell or to a module in the same block cause the *link_block* command to fail. To correct the problem, you must remove the block, correct the Verilog netlist, and reread the design.

Circular or recursive module references cause the *link_block* command to fail. To correct the problem, you must remove the block, correct the Verilog netlist, and reread the design.

Auto Link Many commands automatically link the current block before executing. These automatic links are always incremental, and might not fully rebind block references when the reference library list, view switch list or label switch list is changed. To force a full relink and rebinding of the block, use the *link_block -force -rebind* command.

Feedback

Examples

In the following example, block TOP in library blockLib is linked to the physical hierarchy blocks MID and BOT, and the lib cell library leafCellLib.

```
prompt> link_block TOP
Using libraries: designLib leafCellLib
Linking design TOP
Linking design BOT
Linking design MID
Information: units loaded from library 'leafCellLib' (LNK-040)
Design 'TOP' was successfully linked.
1

The following example shows the linking and relinking of views and
 labels.
The following commands set and get global view switch list.
prompt> set_view_switch_list {design abstract frame outline}
prompt> get_view_switch_list
design abstract frame outline

Similarly, the following commands set and get the global label switch
 list.
prompt> set_label_switch_list {label3 label2 label4 label1}
prompt> get_label_switch_list
label link map: { * {label3 label2 label4 label1 } }

Initial linking of views and labels is shown below :
prompt> current_design TOP
{leafCellLib:TOP.design}

prompt> link_block
Warning: Block 'leafCellLib:TOP.design' is already linked. (LNK-067)
0
prompt> get_blocks MID -hierarchical
{leafCellLib:MID.design}

The following command relinks and blocks are rebound to abstract view and
 label2 label.
prompt> set_view_switch_list {abstract frame design}
prompt> set_label_switch_list {label2 label3 label4 label1}
prompt> link_block -rebind
prompt> get_blocks MID -hierarchical
{leafCellLib:MID/label2.abstract}

The following command fails to rebind as the specified labels of block
 MID are absent.
The binding of block MID remains unchanged.

prompt> set_label_switch_list {label4 label1}
prompt> link_block -rebind
prompt> get_blocks MID -hierarchical
```

Feedback

```
{leafCellLib:MID/label2.abstract}

For more info, see man page of these commands.

---

list_attributes

Lists currently defined attributes.

Syntax

string *list_attributes*

Feedback

```
[-application]
[-class class_name]
[-nosplit]

class_name  string
```

Arguments

`-application`

Lists application attributes as well as user-defined attributes.

`-class class_name`

Limit the listing to attributes of a single class.

To determine the valid classes, use the *get_defined_attributes -return_classes* command.

`-nosplit`

Prevents line splitting and facilitates writing software to extract information from the output. Most of the information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

Description

The *list_attributes* command displays an alphabetically sorted list of currently defined attributes. There are two categories of tool attributes: application-defined and user-defined. By default, *list_attributes* lists all user-defined attributes.

To add the application attributes to the listing, use the *-application* option. Note that there are many application attributes. It is often useful to limit the listing to a specific object class by using the *-class* option.

Examples

The following example lists the attributes defined with the *define_user_attribute* command.

```
prompt> list_attributes

---

list_blocks

List blocks in one or more libraries.

Syntax

int *list_blocks* [-ref_libs] [-lib_cells] [*libraries*]

`list libraries`

Arguments

`-ref_libs`

List blocks from libraries in the current blocks's (or current library's) ref_lib list.

`-lib_cells`

Also list lib_cells within lib_cell libraries.

`libraries`

List blocks only from the given list of libraries.The library specified does not need to be open, and can be a relative or absolute path to a library. If no library is specified, the current_lib is used.

`-refresh`

Refresh library catalog to bring in additional blocks added by another process.

`-time_stamp`

Lists blocks based on their timestamps, with the latest being the last.

Description

The *list_blocks* command lists the blocks from the specified libraries. By default, blocks from all libraries are listed. If a list of libraries are given, then only blocks from those libraries are listed. If the library specified is not opened, it is opened to load and report the block information, and then closed at the end of the command. With the -ref_libs option, blocks are listed from the libraries in the order of the ref_libs for the current block. By default lib cells from lib cell libraries are not list. Lib cells can be listed with the -lib_cells option.

Each library is listed with its name and path. The current library is tagged "current". Libraries containing technology sections are tagged "tech". Lib cell libraries are tagged "lib_cell".

Each block in a library is listed with the block name and the block view type (abstract blackbox design frame outline timing). Each block has a count of the number of blocks containing instances that currently bound to this block.

Open blocks are marked with a "+", modified blocks are marked with a "*". Designs are tagged with their modification date or last saved date. The current block is tagged "current". Lib cell blocks are tagged "lib_cell".

Designs selected to resolve references by the *link_block* command are marked with a ">". This depends on the current block, the view switch list, and the current library's ref_lib list. See the *link_block* command for more information on linking blocks.

Many of these values can be accessed with the *get_attribute* command, see the *get_attribute* and *list_attributes* commands for more information on attributes.

Examples

This example lists the current blocks in libraries.

```
prompt> list_blocks
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>   1 BOT.design Jul-23-09:29
  -    1 BOT.frame  Jul-23-10:14
Lib legacy.nlib /user/joe/mylibs/legacy.nlib tech
  -    1 BOT.design Aug-31-2011
  -    1 MID.design Sep-14-2011
  +    0 TOP.design Oct-03-2011
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>   1 MID.design Jul-23-09:29
  *>   0 TOP.design Jul-23-09:29 current
7
```

This example lists the libraries in the current block's ref_lib list.

```
prompt> list_blocks -ref_libs
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>   1 MID.design Jul-23-09:29
  *>   0 TOP.design Jul-23-09:29 current
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>   1 BOT.design Jul-23-09:29
  -    1 BOT.frame  Jul-23-10:14
4
```

This example also lists the lib cell library.

```
prompt> list_blocks -ref_libs -lib_cells
Lib myDesigns.nlib /user/joe/mylibs/myDesigns.nlib current
  +>   1 MID.design Jul-23-09:29
  *>   0 TOP.design Jul-23-09:29 current
Lib refDesigns.nlib /user/bill/exportLibs/refDesigns.nlib tech
  +>   1 BOT.design Jul-23-09:29
  -    1 BOT.frame  Jul-23-10:14
```

Feedback

```
Lib techlib /project/exportLibs/techlib.nlib lib_cell tech
  -    0 INV.design Jun-27-2011 lib_cell
  +    0 INV.frame  Jun-27-2011 lib_cell
  +>   3 INV.timing Jun-27-2011 lib_cell
  -    0 ND2.design Jun-27-2011 lib_cell
  +    0 ND2.frame  Jun-27-2011 lib_cell
  +>   3 ND2.timing Jun-27-2011 lib_cell
         ...
  -    0 MUX8.design Jun-27-2011 lib_cell
  +    0 MUX8.frame  Jun-27-2011 lib_cell
  +>   1 MUX8.timing Jun-27-2011 lib_cell
2254
```

This example lists blocks in the specified library.

```
prompt> list_blocks legacy.nlib
Lib legacy.nlib /user/joe/mylibs/legacy.nlib tech
  -    1 BOT.design Aug-31-2011
  -    1 MID.design Sep-14-2011
  +    0 TOP.design Oct-03-2011
3
```

Feedback

list_commands

Prints list of all the commands.

Syntax

status *list_commands*

```
[pattern]
[-status {command_status}]
[-options]
[-bg]
```

Data Types

```
pattern          string
command_status   string
```

Arguments

`pattern`

Specifies to print the commands matching this pattern only.

`-status {command_status}`

Specifies to print the commands of this status only.

Status can be one of normal, obsolete, deprecated, retired or all. Default value is all.

`-options`

Specifies to print the list of command options of the commands also.

`-bg`

Specifies to print the list of command supported within redirect -bg.

Description

The *list_commands* command will print names of all the commands and their attributes such as status (normal/deprecated/obsolete) and read-only/undoable by default.

When a pattern is specified after *list_commands*, only commands matching the pattern will be printed. Further the list of commands can be filtered using *-status* option.

When *-options* is specified it will print the command options of the commands with their status (normal/deprecated).

Examples

The following example lists all the commands.

Feedback

```
prompt> list_commands

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name              Attributes
------------              ----------
add_attachment            N
add_buffer                N, U
add_buffer_on_route       N, U
 ...
```

The following example lists all the commands with their command options and options attributes.

```
prompt> list_commands -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name           Attributes     Command Options     Options
 Attributes
------------           ----------     ---------------
 ------------------
add_attachment         N              -file_name          N
                                      -object             N
                                      name                N

add_buffer             N, U           -inverter_pair      N
                                      -lib_cell           N
                                      -new_cell_names     N
                                      ...
 ...
```

The following example lists all the commands which match the pattern 'fi' with their command options and options attributes.

```
prompt> list_commands fi -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name           Attributes     Command Options     Options
 Attributes
------------           ----------     ---------------
 ------------------
find_objects           N, R           -direction          N
                                      -exact              N
                                      -leaf_only          N
                                      ...
```

Feedback

```
fix_signal_em          N              -nets               N
 ...
```

The following example lists all the commands which match the pattern 'map' and have status 'normal' with their command options and options attributes.

```
prompt> list_commands map -status normal -options

Attributes:
N=Normal, D=Deprecated, O=Obsolete
R=Read-only, U=Undoable

Command Name                Attributes     Command Options     Options
 Attributes
------------                ----------     ---------------
 ------------------
map_freeze_silicon          N, U           -eco_cell           N
                                           -map_file           N
                                           -spare_cell         N
                                           ...

map_isolation_cell          N              -domain             N
                                           -lib_cells          N
                                           ...

map_level_shifter_cell      N              -domain             N
                                           -lib_cells          N
                                           ...
 ...
```

The following example lists all the commands supported within redirect -bg.

```
prompt> list_commands -bg

Commands allowed in redirect -bg are:
- all_clocks
- all_connected
 ...
```

---

list_dont_touch_types

Lists the currently defined dont_touch types.

Syntax

status *list_dont_touch_types*

Description

The *list_dont_touch_types* command displays an alphabetically sorted list of currently defined cell and net dont_touch types and their descriptions.

Feedback

Examples

The following command generates the list of dont_touch types for both cells and nets.

```
prompt> list_dont_touch_types

****************************************
Report   : Types of dont_touch
Version :  U-2022.12-DEV
Date     : Fri Jul  8 13:21:38 2022

****************************************

Type                          Description
-----------------------------------------------------------------

dont_touch_dw_sync            Preserve special sequential synchronizers
dtn                           Net in dont_touch network set by
 set_dont_touch_network command
dtn_conn                      Cell connected to dont_touch net
dtn_src                       Output pin of the cell is dont_touch_network
 source
internal_restr                Synopsys internal restriction
1
```

---

list_licenses

Displays a list of licenses currently checked out by the user.

Syntax

```
status list_licenses
```

Arguments

The *list_licenses* command has no arguments.

Description

The *list_licenses* command lists the licenses you currently have checked out. If more than one copy of a license key is checked out, the number of keys checked out is shown in parentheses following the license name.

Feedback

Examples

The following example shows the output from *list_licenses*:

```
prompt> list_licenses
Licenses in use:
        Fusion-Compiler-BE (2)
        Fusion-Compiler-AG (2)
1
```

See Also

---

list_size_only_types

Lists the currently defined size_only types.

Syntax

status *list_size_only_types*

Description

The *list_size_only_types* command displays an alphabetically sorted list of currently defined cell size_only types and their descriptions.

Examples

The following command generates the list of size_only types.

```
prompt > list_size_only_types

****************************************
Report   : Types of size_only
Version :  U-2022.12-DEV
Date     : Fri Jul  8 14:48:05 2022

****************************************

Type                                    Description
-------------------------------------------------------------------------
boundary_no_const_prop                  The restriction is from the
 'set_boundary_optimization -constant_propagation false' command and
 it disables equal and opposite propagation on specified objects. Use
 'remove_boundary_optimization' command to remove the restriction
boundary_opto                           Boundary optimization restriction
```

```
clkdata_iso_sizeonly                    This restriction is to preserve
 clock data isolation cells
cong_keep_structure                     Cell used to preserve structures
 for congestion
seqm_repl                               Cell is size_only from
 register_replication
seqmap_push_out                         Cell is pushed out
 synchronous set reset logic in seqmap and is due to app_option
 compile.seqmap.honor_sync_set_reset
timing                                  Cell with timing constraint
upf_ls                                  Level-shifter cell
upf_repeater                            Repeater cell that is inserted due
 to repeater supply attributes
upf_retention_clamp                     Zero-pin retention clamp cell
user_failsafe_fsm                       Cell is Failsafe FSM logic
1
```

---

list_test_models

Lists the designs in memory that have CTL test models attached to them.

Syntax

status *list_test_models*

Arguments

The *list_test_models* command has no arguments.

Description

This command displays the designs in memory that have CTL test models attached to them. Designs that do not have CTL test model information are not listed. All designs in memory are analyzed, even if they are not a part of the current design or its hierarchy.

Examples

The following example lists the designs that have CTL test model information:

```
prompt> list_test_models
   des_unit
  /remote/my_dir/des_unit_xtol/db/des_unit.db
   des_unit_SCCOMP_COMPRESSOR     /remote/my_dir/des_unit_xtol/ \\
                                  des_unit_SCCOMP_COMPRESSOR.db
   des_unit_SCCOMP_DECOMPRESSOR   /remote/my_dir/des_unit_xtol/ \\
                                  des_unit_SCCOMP_DECOMPRESSOR.db
```

Feedback

list_test_modes

Displays all of the test modes that are defined for the current design.

Syntax

status *list_test_modes*

Arguments

The *list_test_modes* command has no arguments.

Description

The *list_test_modes* command displays all of the modes defined for the current design. The *define_test_mode* command is used to define a mode of operation for a design.

If a design does not have any test modes defined, it displays the message "Design has no test modes."

Examples

The following is an example of the test modes report:

```
prompt> list_test_modes
Test Modes
==========

        Name: ScanCompression_mode
        Type: InternalTest
        Focus:
        Core des_unit_U_decompressor in decompress mode
        Core des_unit_U_compressor in compress mode

        Name: Internal_scan
        Type: InternalTest
        Focus:

        Name: Mission_mode
        Type: Normal
1
```

See Also

- current_design
- current_test_mode
- define_test_mode

Feedback

lminus

Removes one or more named elements from a list and returns a new list.

Syntax

list *lminus*

```
[-exact]
original_list
elements
```

Data Types

```
original_list     list
elements          list
```

Arguments

`[-exact]`

Specifies that the exact pattern is to be matched. By default, *lminus* uses the default match mode of *lsearch*, the *-glob* mode.

original_list

Specifies the list to copy and modify.

elements

Specifies a list of elements to remove from *original_list*.

Description

The *lminus* command removes elements from a list by using the element itself, rather than the index of the element in the list (as in *lreplace*). The *lminus* command uses the *lsearch* and *lreplace* commands to find the elements and replace them with nothing.

If none of the elements are found, a copy of *original_list* is returned.

The *lminus* command is often used in the translation of Design Compiler scripts that use the subtraction operator (-) to remove elements from a list.

Examples

The following example shows the use of the *lminus* command. Notice that no error message is issued if a specified element is not in the list.

```
prompt> set l1 {a b c}
a b c

prompt> set l2 [lminus $l1 {a b d}]
c
```

Feedback

```
prompt> set l3 [lminus $l1 d]
a b c
```

The following example illustrates the use of *lminus* with the *-exact* option:

```
prompt> set l1 {a a[1] a* b[1] b c}
a a[1] a* b[1] b c

prompt> set l2 [lminus $l1 a*]
{b[1]} b c

prompt> set l3 [lminus -exact $l1 a*]
a {a[1]} {b[1]} b c

prompt> set l4 [lminus -exact $l1 {a[1] b[1]} ]
a a* b c
```

load_block_constraints

Loads constraints for child and/or top blocks.

Syntax

```
status load_block_constraints
-type PRECHECK | DEF | UPF | SDC | BUDGET | CLKNET | CTS_CONSTRAINT | BTM
 | FLOORPLAN | SCANDEF
-all_blocks | -blocks block_designs
[-host_options host_option_name]
[-work_dir directory_name]
```

Data Types

```
block_designs     list
host_option_name  string
directory_name    string
```

Arguments

```
-type PRECHECK | DEF | UPF | SDC | BUDGET | CLKNET | CTS_CONSTRAINT |
BTM | FLOORPLAN | SCANDEF
```

Specifies the type(s) of constraints to load or check. Valid values are: PRECHECK, DEF, UPF, SDC, BUDGET, CLKNET, CTS_CONSTRAINT, BTM, FLOORPLAN, SCANDEF. The values are case-insensitive.

The types, except *PRECHECK*, correspond to the keywords used in the constraint mapping file set through *set_constraint_mapping_file* command.

When type *PRECHECK* is specified, the tool prints information about the physical hierarchy tree of the design. If any other type is specified together with

Feedback

type *PRECHECK*, the information in the constraint mapping file related to the specified type is also reported.

When the command is issued without type *PRECHECK*, the tool loads the constraint of the specified types to the specified blocks according to information in the constraint mapping file.

You can specify *-type* multiple times with one *load_block_constraints* command.

`-all_blocks`

Loads constraints for all the child blocks in the current design and the current design itself, if the specified constraint types for the block are available in the constraint mapping file.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and runs the blocks in a bottom-up order.

This option is mutually exclusive with *-blocks*. One and only one of them should be specified.

`-blocks` *`block_designs`*

Specifies the list of child block designs to load constraints to.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and runs the blocks in a bottom-up order.

This option is mutually exclusive with *-all_blocks*. One and only one of them should be specified.

`-host_options` *`host_option_name`*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

`-work_dir` *`directory_name`*

Writes all generated scripts and log files to the specified directory.

By default, the work directory is *./work_dir*. If there are host option settings for distributed processing, the work_dir setting from the host option is used. This option takes precedence over the default and the host option setting.

Description

This command loads constraints for child blocks as well as for top level.

The tool gets the constraint files from the constraint mapping file. See the man page for *set_constraint_mapping_file* for details of how to set up the constraint mapping file.

DEF constraints are loaded through command *read_def*.

Feedback

UPF constraints are loaded through command *load_upf* and only when UPF constraints has not been loaded previously for a given block. After *load_upf* is run, *commit_upf* is performed.

SDC constraints are loaded through command *source*. Operations *remove_modes -all* and *remove_corners -all* are performed before loading the SDC constraints for a block.

BTM stands for *blackbox timing model*. BTM constraints are loaded using command *source*.

FLOORPLAN, CLKNET and BUDGET constraints are loaded through command *source*.

CTS_CONSTRAINT constraints are loaded through command *source*. Then *synthesize_clock_trunks* is performed on the block.

Only blocks whose specified constraint types that are available in the constraint mapping file are run. If the abstract view exists for a block, the same type of abstract would be re-created after loading the constraints for that block.

If a block started as an outline view, command *expand_outline* is first performed on the block. Then constraints are loaded for the block and the abstract view is created. Any necessary *change_abstract* commands are added for any parent block where it is needed.

In a multi-level physical hierarchy design, the tool determines the nesting order of the blocks and run the blocks in a bottom-up order.

Examples

The following example UPF and SDC for all the child blocks as well as the top level are loaded.

```
prompt> set_constraint_mapping_file ./split/mapfile
prompt> load_block_constraints -all_blocks -type SDC -type UPF
```

The following example shows that FLOORPLAN constraints are loaded to all the child blocks as well as the top level.

```
prompt> set_constraint_mapping_file ./floorplan/mapfile
prompt> load_block_constraints -all_blocks -type FLOORPLAN
```

The following example CTS constraints are loaded to the block BOT and *synthesize_clock_trunks* is performed on BLK_A.

```
prompt> load_block_constraints -blocks BLK_A -type cts_constraint
```

The following example prints information about the design's physical hierarchy.

```
prompt> load_block_constraints -type precheck
```

Feedback

---

load_busplans

Loads XML data and re-creates busplans.

Syntax

status *load_busplans*

```
-xml_file filename
[-only_create]
[-replace_existing]
[-verbose]
[-ignore_mib_compliance]
[-buses patterns]
```

Data Types

```
filename  string
patterns  string (patterns)
```

Arguments

`-xml_file filename`

Specifies the name of the XML data file to read. The XML file should have the same format as written by the *write_busplans -xml_file filename* command.

`-only_create`

Creates only the start and end parts of the busplans in the data file. No virtual registers or pins will be re-inserted into the busplans.

`-replace_existing`

Remove the existing busplan, specified by the *-buses patterns* argument, before re-creating it. Matching is done only based on busplan name; no other checking is done. If not specified, busplans that already exist are skipped.

`-verbose`

Prints more detail about each busplan as it is being re-created. Messages include errors detected during the process. Otherwise, the command prints only a summary at the end.

Feedback

`-ignore_mib_compliance`

Do not try to re-create busplans in the order required for MIB compliance. As well, if any required MIB parent busplans are not in the explicit list of busplans to re-create, do NOT add them to the list automatically.

By default, MIB parent busplans will be created first, even if they appear later in the XML file, or are not in the explicit list of busplans to re-create.

`-buses` *`patterns`*

Specifies the names of busplans to re-create, if found inside the XML data file. Pattern matching is done based on the Tcl "string match" algorithm. Multiple patterns can be included in one Tcl list such as: -buses {busABC* busDEF* bus3}.

Description

Loads and re-creates busplans from an XML data file, such as one previously written by *write_busplans -xml_file filename*.

Examples

The following example loads a busplan from the XML-formatted file named busplan.xml

```
prompt> load_busplans -xml_file busplan.xml
```

See Also

- create_busplans
- get_busplans

---

load_metal_pattern_density

Reads the metal density information of hard macro, including layer, bounding box and metal density value.

Syntax

int *load_metal_pattern_density*

Arguments

This command has no arguments.

Feedback

Description

The *load_metal_pattern_density* command reads the metal density information for hard macros. The information includes layer, bounding box and metal density value. Using the command in the GUI, you can configure the visual metal pattern density map.

Examples

The following example loads the metal density information for the macro.

```
prompt> load_metal_pattern_density
1
```

---

load_of

Gets the capacitance of a library cell pin.

Syntax

float *load_of*

```
        lib_pin
```

Data Types

```
lib_pin       collection
```

Arguments

lib_pin

Specifies the name of the library cell pin, or a collection that contains the library cell pin, for which to get the capacitance. But the tool wrill only return the capacitance for first lib pin in the collection.

Description

The *load_of* command returns the capacitance of the first given library cell pin.

---

load_ssf

Reads in a file in Safety Specification Format (SSF).

Syntax

status *load_ssf*

```
file_name
[-allow_tcl_vars namespace_list]
```

Feedback

Data Types

file_name	string
namespace_list	list

Arguments

file_name

Specifies the name of the file that contains the SSF file to be read. The value can be a relative path or a full path to that file. The file must exist at the specified location and should be readable.

-allow_tcl_vars *namespace_list*

Specifies the namespaces, whose Tcl variables should be supported during ssf file read. Namespace name should only contain either alphanumeric or underscore characters. If namespace "global" is specified all the global Tcl variables will be supported. This is optional.

Description

This command reads in the specified SSF file. It interprets the SSF commands contained in that file, translates them into the appropriate functional safety intents, and updates the design accordingly. Currently, safety registers and safety cores are supported, therefore running the *load_ssf* command creates or update objects of one or more in those categories. The top level of the current design is used as the default scope. This command supports undo and redo operations.

This command has an incremental effect when invoked multiple times. This means that reading a new SSF file does not delete the existing design objects, created either by a previous SSF file, or manually through UI commands. New objects are created and added to the database.

The reader performs syntactic as well as semantic checks for each entry in the input file. These checks include the following:

Unrecognized command name or command option Missing ssf_version command at the beginning of the file Repeated ssf_version command Unsupported version of input file (marked using ssf_version command) Other checks such as correctness of object specification, option value check, range check, and so on.

When any syntax or semantic error is encountered while reading the file, the *load_ssf* command stops reading and returns to the prompt with a Tcl error.

Examples

The following example loads the SSF script file named top.ssf.

```
prompt> load_ssf top.ssf
1
```

Feedback

The following example loads the SSF script file named top1.ssf and supporting the global variable "ssize" and ssf namespace variable "::ssf::distance" specified inside top1.ssf file.

```
prompt> namespace eval ssf { variable distance 6 }
prompt> set ssize 2
prompt> load_ssf top1.ssf -allow_tcl_vars {ssf global}
1
```

---

load_upf

Reads in a script in Unified Power Format (UPF) format.

Syntax

```
status load_upf
[-scope instance_name]
[-noecho]
[-strict_check true | false]
[-supplemental supf_file_name]
file_name
```

Data Types

```
instance_name     string
file_name         string
```

Arguments

`-scope instance_name`

Specifies the scope where the UPF commands contained in the *file_name* file are to be executed.

If you do not use this option, the command uses the current scope.

`-noecho`

If specified, commands in the UPF file are not echoed to the output.

`-strict_check true | false`

Specifies whether to perform strict name matching during execution of the UPF commands. Use this option only in the golden UPF mode.

Feedback

Set this option to *true* when you load the golden UPF file into the synthesis tool for the very first time, when object names in the UPF commands are expected to match object names in the design exactly.

Set this option to *false* when you reapply the golden UPF file any time after the tool has operated on the design, when object names in the file are not expected to match object names in the design due to optimization, grouping, and wildcard name expansion. In this case, the tool identifies objects using rule-based matching and name map file, if any.

The default value of this option will be *false* if the design is fully mapped and *true* if not.

In front-end mode, the default setting is *true*; if you do not use the *-strict_check* option in the golden UPF mode, the tool uses strict name checking.

In back-end mode, the default setting is *false*; if you do not use the *-strict_check* option in the golden UPF mode, the tool uses non-strict name checking.

`-supplemental` *`supf_file_name`*

Specifies the name of the supplemental UPF file to be read. This option is supported only in the golden UPF mode.

When loading a UPF file with this option, any UPF that is not explicitly preceded by "set derived_upf false" is designated as "set derived_upf true". Supplemental UPF content is always loaded with the *-strict_check true* setting.

`file_name`

Specifies the name of the file that contains the UPF script to be read.

Description

The *load_upf* command sets the scope to the specified instance and executes the set of UPF commands in the specified file. When the command completes, it restores the current scope to what it was before. The commands are executed in the same way as the Tcl *source* command.

The tool automatically identifies the UPF constraint type based on the setting of the Synopsys-specific *derived_upf* variable, which is set on the design UPF by the Synopsys implementation tools when they update the UPF constraints, such as by adding *connect_supply_net* constraints. When the *derived_upf* variable is *true*, the constraints loaded by the *load_upf* command are considered supplemental constraints. When this variable is *false*, the constraints loaded by the *load_upf* command are considered golden constraints.

The following example shows a UPF file that has been modified by the tool:

```
## Constraints below are generated by icc2. Please do not modify.
set derived_upf true
```

Feedback

```
if ($derived_upf) {
   connect_supply_net VDD_VSS.power -ports {
      u0_0/U41/VDD \
      u0_0/U24/VDD u0_0/U4/VDD \
      u0_1/U321/VDD }
}
set derived_upf false
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example loads the UPF script file named top.upf.

```
prompt> load_upf top.upf
1
```

---

log_trace

Control creation of a replay log of traced commands.

Syntax

string *log_trace* [-start file_name|-stop|-pause|-resume] [-log log_string] [-quiet]

string *file_name* string *log_string*

Arguments

`-start` *file-Name*

This option is mutually exclusive with -stop, -pause, and -resume. The argument is the pathname of the file to which the replay trace log is output. The option opens a file for output and begins logging command execution strings and application variable changes. Note that if the file already exists, the command overwrites the existing file. There can only be a single replay trace log output at any time.

Feedback

`-stop`

This option is mutually exclusive with -start, -pause, and -resume. This option stops replay trace log output and closes the log file. Once stopped, the replay log cannot be repopened for appending.

`-pause`

This option is mutually exclusive with -start, -stop, and -resume. This option pauses replay trace log output. Execution of all commands and application variable settings are ignored and omitted from the log until output is resumed with -resume.

Note that pausing replay log output may render the resulting log unable to replay or incapable of replicating tool results.

`-resume`

This option is mutually exclusive with -start, -stop, and -pause. This option resumes replay trace log output.

`-log` *`log_string`*

This option outputs the given log_string, verbatim, to the replay trace log. The option may be used to explicitly log a command invocation or a comment. If the string is a comment, it must start with the Tcl comment character '#'.

`-quiet`

If given, this option causes the command to ignore error conditions such as an attempt to pause the trace log output before it is started. The command will exit quietly when it encounters an error condition.

Description

The *log_trace* command performs operations related to creating a flat replay log of traced command execution and application variable changes. All options are optional. Upon successful completion, the command returns the pathname of the trace log file, if any, or an error message if the command fails.

Trace log output contains a comment header with the tool name and version, and the date and time when trace log output was started.

The resulting replay log is not 100% guaranteed to be able to replay or to reproduce tool results. One reason is that the tool execution environment may be different. If any operations are performed during log creation that would further compromise the ability to replay the resulting log or to replicate tool results, a warning message is appended to the log. Such operations including pausing log output.

Invoking the *log_trace* with no options will report the current status of logging: on, paused, or off, followed by the currently open log file name, if any.

Feedback

Examples

The following example shows reporting of the log status before starting trace logging.

```
prompt> log_trace
off
```

The following example starts trace log creation.

```
prompt> log_trace -start ./tracelog.tcl
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

The following example pauses, then resumes log creation.

```
prompt> log_trace -pause
/an/absolute/path/.tracelog.tcl
prompt> log_trace
paused: /an/absolute/path/.tracelog.tcl
prompt> log_trace -resume
/an/absolute/path/.tracelog.tcl
prompt> log_trace
on: /an/absolute/path/.tracelog.tcl
```

---

lookup_eff_vd

Shows Eff-VD flow results in the shell or as a user-defined map.

Syntax

status *lookup_eff_vd*

```
[-cells inst_names_list]
[-nets net_names_list]
[-layers layer_names_list]
\#[-type type_number]
[-show_map]
```

Data Types

```
inst_names_list  string
net_names_list   string
```

Feedback

```
layer_names_list string
\#type_number      integer
```

Arguments

`-cells inst_names_list`

Specifies the instances to show results.

`-nets net_names_list`

Specifies the power and ground supply nets to show results.

`-layers layer_names_list`

Specifies the layers to show results.

\#.IP "-type *type_number*" \#Specifies the type_number to show results. \#For static: 0=static \#For dynamic: 0=avg_tw, 1=max_tw, 2=min_tw, 3=min_pg_sim \# \#NOTE: Only applies to instance Eff-VD results.

`-show_map`

Shows Eff-VD flow results as a user-defined map. If not specified, shows Eff-VD flow results in the shell.

NOTE: Requires gui_start

Description

Shows Eff-VD flow results in the shell or as a user-defined map.

Examples

The following example uses Eff-VD flow to perform an analysis that includes node voltage results and shows the results as a user-defined map.

The text report generated is for nets VDD, VSS and layers METAL4, METAL5, sorted by layer, net, then node_voltage, and only including the first 99999 results (limited by Redhawk-SC's internal limit).

```
prompt> set_app_options -name rail.enable_eff_vd_flow -value 1
prompt> set_app_options -name rail.enable_node_voltage -value 1
prompt> set_app_options -name rail.node_voltage_sort_fields -value {layer
 net node_voltage}
prompt> set_app_options -name rail.node_voltage_max_lines -value 99999
prompt> analyze_rail -voltage_drop static -nets {VDD VSS}
prompt> gui_start
prompt> lookup_eff_vd -net {VDD VSS} -layer {METAL4 METAL5} -show_map
```

---

ls

Lists the contents of a directory.

Syntax

string *ls* [*filename* ...]

```
string filename
```

Arguments

filename

Provides the name of a directory or filename, or a pattern which matches files or directories.

Description

If no argument is specified, the contents of the current directory are listed. For each *filename* matching a directory, *ls* lists the contents of that directory. If *filename* matches a file name, the file name is listed.

Examples

```
shell> ls *.db *.pt
test1.pt          c1.db          c3.db          c5.db
test2.pt          c2.db          c4.db          c6.db
```

Feedback

m

magnet_placement

Performs magnet placement on current design.

Syntax

status *magnet_placement*

```
[-move_fixed]
[-mark_fixed]
[-move_legalize_only]
[-mark_legalize_only]
[-stop_by_sequential_cells]
[-stop_on_sequential_cells]
[-exclude_buffers]
[-avoid_soft_blockage]
[-only_report_magnet_cells]
[-get_collection]
[-logical_levels level]
[-multiple_long_port_mode auto | nearby]
[-cells object_list]
[-stop_points object_list]
[-hierarchy_mode default | block | all]
[-enable_runtime]
magnet_objects
```

Data Types

```
level             integer
object_list       collection
magnet_objects    collection
```

Arguments

`-move_fixed`

Specifies that the cell marked as fixed can be moved. By default, the fixed cells and the cells behind them cannot be pulled.

`-mark_fixed`

Specifies that the cells are to be marked fixed after running the *magnet_placement* command. By default, no cell is marked as fixed after the command. This option is mutually exclusive with the *-mark_legalize_only* option.

`-move_legalize_only`

Specifies that a cell marked as legalize_only can be moved. By default, legalize_only cells cannot be moved.

Feedback

`-mark_legalize_only`

Specifies that the cells are to be marked as legalize_only after running the *magnet_placement* command. By default, no cell is marked as legalize_only after the command. This option is mutually exclusive with the *-mark_fixed* option.

`-stop_by_sequential_cells`

Stops pulling cells when a sequential cell is encountered during level traversal. The sequential cell is not pulled itself. This option is mutually exclusive with the *-cells*, *-stop_on_sequential_cells* and *-stop_points* options.

By default, the cells in logical level 1 only are considered for pulling. Logical level can be changed using *-logical_level* command option.

`-stop_on_sequential_cells`

Stops pulling cells when a sequential cell is encountered during level traversal. The sequential cell is pulled itself. This option is mutually exclusive with the *-cells*, *-stop_by_sequential_cells* and *-stop_points* options.

By default, the cells in logical level 1 only are considered for pulling. Logical level can be changed using *-logical_level* command option.

`-exclude_buffers`

Ignores buffers and inverters when calculating the level. Buffers and inverters are pulled like normal cells but are skipped over for level determination. By default, buffers and inverters are considered as one level of logic.

`-avoid_soft_blockage`

Avoids placing cells in soft placement blockages. By default, hard placement blockage are honored and cells might be placed within soft blockages.

`-only_report_magnet_cells`

Only report the magnet cells to be pulled while no cells are pulled. This option is mutually exclusive with the *-get_collection* option.

`-get_collection`

Return the pulled cells as a collection while pulling them. Use this option with any other options except the *-only_report_magnet_cells* option to easily get the collection of pulled cells while pulling them within single command.

`-logical_levels` *`level`*

Specifies the number of logical levels to pull. By default, *level* is 1 and only the first-level cells are pulled. This option is mutually exclusive with the *-cells* option.

Feedback

`-multiple_long_port_mode auto | nearby`

Specifies how cells are pulled for multiple or long ports. The command supports two modes: auto and nearby.

When 'nearby' set for long port, command pulls placed cells to the nearest location on the port and unplaced cells nearby the port center. When 'nearby' set for multiple port, the command pulls placed cells to one of the nearest port terminals and unplaced cells nearby any one of terminals.

When 'auto' set for a long port, the command places cells evenly near the port. When 'auto' set for a multiple port, command places cells evenly nearby each port terminal.

By default, multiple ports and long port not supported without setting this option.

`-cells` *`object_list`*

Pulls only the cells in the specified object list. You specify only cell objects in the object list. This option is mutually exclusive with *-logical_levels* and *-stop_by_sequential_cells*.

The cells that you specify should form an intact datapath with magnet object. For example, if magnet object connects to cell_a, and cell_a connects to cell_b, you should specify both cell_a and cell_b. These cells do not have to be a timing path.

`-stop_points` *`object_list`*

Pulls only the cells that are on the paths between the magnet objects and the given stop_point objects. The stop_point objects can be lists of any pin, port, or cell objects.

This option is mutually exclusive with the *-logical_levels*, *-exclude_buffers*, *-stop_by_sequential_cells*, and *-cells* options.

`-hierarchy_mode default | block | all`

Specifies how the command traces cells in the hierarchy in hierarchy placing mode. When this option is specified, all cell instances within each hierarchical block that are connected to the magnet object are pulled toward it. All hierarchies specified by using the *-cells* option are placed one by one.

This option must be used together with the *-cells* option, which by default accepts only flat cell instances as input. When this option is specified, the *-cells* option accepts only hierarchical cell instances as input.

Feedback

The valid modes are:

- default: The tool traces through only buffers and inverters when traversing from the magnet object to the cells within the specified hierarchical block. This is the default setting.
- block: The tool does not trace through any cell when traversing from the magnet object to the cells within the hierarchical block. The tool pulls the cells of the specified hierarchical block toward the magnet object only if they are directly connected to the magnet object. This is the most restrictive setting.
- all: The tool traces through all combinational cells when traversing from the magnet object to the cells within the specified hierarchical block. However, it does not trace through sequential cells. This is the least restrictive setting.

magnet_objects

Specifies the magnet objects. A magnet object should be a fixed object, for example, a fixed macro cell, a fixed standard cell, a pin of a fixed macro cell, or an I/O pin. Objects like vias and blockages are not allowed to be magnets.

`-enable_runtime`

Enables fast runtime flow for the Magnet Placement command.

Description

The command defines a set of objects as magnets and pulls the neighboring cells up to a specified logical level closer to the magnet.

It is considered a best practice to run this command before coarse placement, so that sufficient areas are available for magnet placement operation.

A large macro with many placeable standard cell neighbors can be used to ensure that the standard cells are placed close to the macro, resulting in better timing and congestion.

If a net has a fanouts number larger than 1000, the command ignores the net because pulling such a large high-fanout net might cause runtime and congestion issues.

The effect of magnet placement is not preserved from one invocation to another. For example, consider a design where cells A and B are made magnets and there are cells that are connected to both of them through possibly multiple levels. Running *magnet_placement A* and then *magnet_placement B* could result in a different result from running commands *magnet_placement [get_cells "A B"]* together.

If the *magnet_placement* command is invoked after the *create_placement* command, the cell overlap issues might occur since there could be standard cells already placed. You can run the *legalize_placement* command to remove the overlaps.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example performs magnet placement on the *INST_1* cell:

```
prompt> magnet_placement [get_cells "INST_1"]
```

The following example performs magnet placement and marks the moved cells as fixed afterwards:

```
prompt> magnet_placement -mark_fixed [get_cells "INST_2"]
```

The following example pulls two levels of cells to *INST_2*.

```
prompt> magnet_placement -logical_levels 2 \\
   [get_cells "INST_2"]
```

The following example pulls the specified cells to INST_3.

```
prompt> magnet_placement INST_3 -cells {Cel_1 Cel_2 Cel_3}
```

- legalize_placement

---

man

Displays reference manual pages.

Syntax

```
string man
topic
```

Data Types

```
topic      string
```

Arguments

topic

Specifies the subject to display. Available topics include commands, variables, and error messages

Feedback

Description

The *man* command displays the online manual page for a command, variable, or error message. You can write man pages for your own Tcl procedures and access them with the *man* command by setting the *sh_user_man_path* variable to an appropriate value. See the man page for the *sh_user_man_path* variable for details.

Examples

The following command displays the man page for the *echo* command:

```
prompt> man echo
```

The following command displays the man page for the error message CMD-025:

```
prompt> man CMD-025
```

See Also

- sh_user_man_path

---

map_freeze_silicon

Manually maps cells to the specified spare cells.

Syntax

status *map_freeze_silicon*

```
-eco_cell eco_cell_names
-spare_cell spare_cell_names
[-filler_map_strategy pack_left | pack_right | pack_top | pack_bottom |
 closest ]
[-lib_cells_for_filler_recovery psc_filler_lib_cells ]
```

status *map_freeze_silicon*

```
-eco_cell eco_cell_names
-spare_cell spare_cell_names
-advanced_nodes
[-skip_rule_check]
[-lib_cells_for_filler_recovery psc_filler_lib_cells ]
```

status *map_freeze_silicon*

```
-map_file map_file_name
[-lib_cells_for_filler_recovery psc_filler_lib_cells ]
```

Feedback

Data Types

eco_cell_names	list of cells
spare_cell_names	list of cells
map_file_name	string
psc_filler_lib_cells	list of library cells

Arguments

`-eco_cell` *eco_cell_names*

Specifies one or multiple cells to be mapped. The specified cells should already exist in the design, whose attribute "is_fs_eco_add" are true and "eco_change_status" are one of create_cell, change_link, add_buffer, add_buffer_on_route, size_cell, eco_placed. If multiple cells are specified and one of them is with error, none of them will be mapped.

This option is mutually exclusive with the *-map_file* option and is used together with the *-spare_cell* option.

`-spare_cell` *spare_cell_names*

Specifies one or multiple spare cells used for mapping. For programmable spare cell (PSC) mapping, user can specify one or multiple adjacent PSC fillers. But for non-PSC mapping, user can only specify one spare cell. These cells should already exist in the design and they should be spare cells.

This option is mutually exclusive with the *-map_file* option and is used together with the *-eco_cell* option.

`-filler_map_strategy pack_left | pack_right | pack_top | pack_bottom | closest`

Specifies the location of the ECO cell inside the specified programmable spare cell (PSC) filler. It can only be used when the spare cell is a PSC filler. Default strategy is "pack_left" or "pack_bottom", which means ECO cells will be put one by one from left or bottom of the specified PSC filler. "pack_right" or "pack_top" means ECO cells will be put one by one from right or top of the specified PSC filler. "closest" means a ECO cell will be put at the closest valid location inside the specified PSC filler. "closest" strategy is designed for ECO cells which are already put near expected locations. In this strategy, attribute is_placed of ECO cells must be true.

This option is mutually exclusive with the *-map_file* option and can only be used together with the *-eco_cell* and *-spare_cell* option. When *-map_file* is used, strategy can be specified inside the map file.

`-advanced_nodes`

This option is mutually exclusive with the *-map_file* option and can only be used together with the *-eco_cell* and *-spare_cell* option.*-filler_map_strategy* option.

Feedback

`-skip_rule_check`

This option skips rule check to force mapping eco cells. It is required to use with advanced_nodes option.

`-map_file` *`map_file_name`*

Specifies the name of the map file.

The following is the format of a map file:

```
# Comment should starts by "#". "#" must be the first character
 of the comment line
# Each line specify a pair of ECO cell and spare cell, separating
 by a space
eco_cell_1 spare_cell_1
eco_cell_2 spare_cell_2
 ...        ...
# format is same for programmable spare cell (PSC) filler or
 non-PSC spare
# cell, tool will detect them automatically.
eco_cell_3 psc_filler_3
 ...        ...
# To specify filler_map_strategy, just put it after spare cell
 (must be a
# PSC filler), separating by a space; If not specified, default
 is also
# "pack_left" or "pack_bottom"
eco_cell_4 psc_filler_4 pack_top
# To map multi ECO cells to same PSC filler, put them in a {}
# If multiple cells are specified and one of them is with error,
 none of
# them will be mapped.
{eco_cell_5_1 eco_cell_5_2} psc_filler_5
# It allows that specify multiple PSC fillers in the same mapping
 pair. But
# these PSC fillers must be adjacent and have the same PSC type.
 Then they
# can be merged together for mapping large ECO cell or multiple
 ECO cells.
eco_cell_6 {psc_filler_6_1 psc_filler_6_2}
{eco_cell_7_1 eco_cell_7_2} {psc_filler_7_1 psc_filler_7_2}
```

Error lines will not be mapped, while other lines in the map file still will be mapped. Same ECO cell / PSC filler cannot be specified two times in a map file, otherwise both lines in which they appear will not be executed.

`-lib_cells_for_filler_recovery`

Specifies the programmable spare cell (PSC) filler lib cells to fill the rest of the specified PSC filler as spare cell, after mapping. When the PSC filler as spare cell is larger than the ECO cell, the rest of it will be filled by newly created PSC fillers of same PSC type. If this option is specified, only lib cells specified will

Feedback

be used for such filling. Otherwise, all available PSC lib cells in the reference libraries will be used.

Description

This command maps the freeze silicon added ECO cell to the specified spare cell, to use the silicon of the spare cell as the ECO cell. The location, orientation, and PG connection of the spare cell will be inherited by the ECO cell. Then the original spare cell itself will be deleted from database. After mapping, an ECO routing command can be used to complete the routing.

In this command, ECO cell must be mapped to spare cell of a compatible lib cell, which means either:

1. ECO cell and spare cell are of same reference lib cell. In this scenario, user can specify only one ECO cell and one spare cell in the mapping pair.
2. Spare cell is programmable spare cell (PSC) filler, whose PSC type is same as the PSC type of the ECO cell or meets PSC mapping rule. In this scenario, user can specify one or multiple PSC fillers with the same PSC type of ECO cells (or meeting PSC mapping rule) in the mapping pair.

This command will detect these 2 types of mapping automatically.

This command support specify multiple ECO cells or spare PSC fillers. However, this should only be used when it is necessary:

1. Have to specify multiple ECO cells to be mapped by splitting PSC fillers.
2. Have to specify multiple PSC fillers and merge them to map ECO cells. Otherwise, e.g., if you want to map eco_cell1 to psc_filler1 and eco_cell2 to psc_filler2, explicitly specify them in separate *map_freeze_silicon* commands or separate lines in the map file. Otherwise the mapping result might be different than your expectation.

You can specify the ECO cell and spare cell either by using the *-eco_cell* and *-spare_cell* options, or by using a map file.

If PSC filler is larger than the ECO cell, the rest of it will be filled by fillers of same PSC type.

Behavior of this command is same whether the *design.eco_freeze_silicon_mode* application option is true or false.

Examples

The following example uses *map_freeze_silicon*.

```
prompt> map_freeze_silicon -eco_cell h1_1/U3 -spare_cell spare_buf_0
```

The following example uses *map_freeze_silicon* and specifies a map file.

Feedback

```
prompt> map_freeze_silicon -map_file map_file
```

The following example uses *map_freeze_silicon* and specifies a programmable spare cell (PSC) filler.

```
prompt> map_freeze_silicon -eco_cell {h1/U3 h2/U4} \\
   -spare_cell filler16 -filler_map_strategy pack_right \\
   -lib_cells_for_filler_recovery {FILL1 FILL2}
```

See Also

- place_freeze_silicon

---

map_isolation_cell

Specifies how to map or remap the isolation and enable level-shifter cells belonging to the specified isolation strategy.

Syntax

status *map_isolation_cell*

```
isolation_strategy
-domain power_domain
-lib_cells lib_cells
```

Data Types

```
isolation_strategy    string
power_domain          string
lib_cells             list
```

Arguments

isolation_strategy

Specifies the UPF isolation strategy name. The name of the isolation strategy must be unique within the specified power domain.

-domain *power_domain*

Specifies the name of the power domain name to which this isolation strategy belongs.

-lib_cells *lib_cells*

Specifies a list of the target library cells to be used for the isolation mapping.

Description

This command defines how the *compile* command performs the mapping of an isolation cell. All isolation cells that match the strategy will be mapped or remapped to one of the

Feedback

cells specified with the *-lib_cells* option with the highest priority. If no mapped lib cell cannot be used, the tool will select available cell from all libraries. Resizing is done if required; Mapped lib cells have higher priority than library cells.

You can also specify enable level-shifter cells using the *-lib_cell* option. If the isolation cells are later changed to enable level-shifter cells in the technology library, the cells can only be mapped to the one of the enable level-shifter cells specified with this command.

Examples

In the following example, the isolation cells belonging to the strategy named isolation_1 will be mapped to the LIB_HICLAMP0X2 or LIB_HICLAMP0X4 library cells with the highest priority:

```
prompt> map_isolation_cell isolation_1 -domain PD1 \\
 -lib_cells {LIB_HICLAMP0X2 LIB_HICLAMP0X4}
```

See Also

- set_isolation
- set_isolation_control

---

map_level_shifter_cell

Specifies that the level-shifter cells belonging to the specified strategy can only be mapped to a subset of the library cells.

Syntax

status *map_level_shifter_cell*

```
level_shifter_strategy
-domain power_domain
-lib_cells lib_cells
```

Data Types

```
level_shifter_strategy      string
power_domain                string
lib_cells                   list
```

Arguments

level_shifter_strategy

Specifies the UPF level-shifter strategy name. The level-shifter strategy name must be unique within the specified power domain.

Feedback

`-domain` *power_domain*

Specifies the power domain name to which this level-shifter strategy belongs.

`-lib_cells` *lib_cells*

Specifies a list of library cells that can be used to map to the level-shifter cells.

Description

This command defines how the *compile* command maps the level-shifter cells. All level-shifter cells belonging to the specified strategy are mapped to one of the library cells specified in the *-lib_cells* list with the highest priority. If no library cell is available from the mapped list, the tool will select available cells from all libraries. Resizing is done if required; Mapped lib cells have higher priority than library cells.

If a valid solution cannot be reached using any library cell, no level-shifter cells are inserted. For example, if the level shifters specified in the *-lib_cells* option cannot be used to shift between the required voltage levels, and no other library cell can be used neither, the tool does not insert any level-shifter cell.

For mapping the enable level-shifter cells, use the *map_isolation_cell* command.

Examples

In the following example the level-shifter cells belonging to the strategy named VL_1 will be mapped to the LIB_LSHIX2 or LIB_LSHIX4 library cells with the highest priority:

```
prompt> map_level_shifter_cell LVL_1 -domain PD1 \\
 -lib_cells {LIB_LSHIX2 LIB_LSHIX4}
```

See Also

- map_isolation_cell
- set_level_shifter

---

map_power_switch

Defines which power switch library cells to use for the mapping of the given UPF power switch.

Syntax

status *map_power_switch*

```
switch_name
-domain domain_name
-lib_cells list
```

Feedback

Data Types

```
switch_name    string
domain_name    string
list     list
```

Arguments

switch_name

Specifies the name of the power switch to be mapped using the specified library cells. This is a required option.

-domain *domain_name*

If specified, uses the scope of the given power domain as the scope in which the power switch will be looked for. If no domain option is specified, the current scope will be used.

-lib_cells *list*

Specifies a list of target library cells to use for the power switch cell mapping. This is a required option.

Description

This command is used to explicitly specify which library power switch cells are mapped for the corresponding UPF power switch.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example maps the switch_1A power switch in the power domain named myPowerDomain with the lib2A/switch2A library cell:

```
prompt> map_power_switch switch_1A \\
        -domain myPowerDomain -lib_cells lib2A/switch2A
1
```

See Also

- create_power_switch
- get_lib_cells

---

map_retention_cell

Defines how to map the unmapped sequential cells to retention cells for the specified UPF retention strategy of the power domain.

Feedback

Syntax

```
status map_retention_cell
retention_strategy
-domain power_domain
[-lib_cells lib_cells]
[-lib_cell_type lib_cell_type]
[-elements objects]
[-lib_model_name name {-port port_name net_ref}*]
```

Data Types

```
retention_strategy    string
power_domain          string
lib_cells             list
lib_cell_type         string
objects               list
port_name             string
net_ref               string
```

Arguments

retention_strategy

Specifies the UPF retention strategy name. The retention strategy name should be unique within the specified power domain.

-domain *power_domain*

Specifies the power domain name that this UPF retention strategy will be applied to.

-lib_cells *lib_cells*

Specifies a list of target library lib cells to be used for the retention mapping.

-lib_cell_type *lib_cell_type*

Specifies the retention type to be used for the retention mapping.

-elements *objects*

Specifies that retention mapping only applies to the sequential cells within the specified objects. The objects can be a list of hierarchical cells, leaf cells, or seqgen output signal nets.

-lib_model_name *name* {-port *port_name net_ref*}*

Specifies the retention library cell or behavioral model and associated port connectivity for verification tools.

Description

This command defines how the retention cells are mapped and implemented. In front-end mode, the tool ignores *-elements* and applies this mapping directive to all sequential cells

Feedback

to which the specified retention strategy applies. Also, *-elements* does not get written out in UPF' file.

In back-end mode, the tool ignores *-elements* and applies this mapping directive to all mapped registers to which the specified retention strategy applies. Also, *-elements* does not get written out in UPF' file.

The retention cell specified using the *-lib_model_name* option is not used during implementation. The *-lib_model_name* option is not written out in the UPF' file post compile.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example maps the sequential cells under the *retention_1* retention strategy to the *CLK_LOW* retention type:

```
prompt> map_retention_cell retention_1 \\
        -domain PD1 -lib_cell_type CLK_LOW
```

The following example maps the sequential cells under the retention_2 retention strategy to the RSDFCD1HVT and RSDFCD2HVT retention library cells. The *-lib_model_name* option specifies the retention library cell, port name, and net reference used by the verification tools.

```
prompt> map_retention_cell retention_2 \\
        -domain PDM -lib_cells { RSDFCD1HVT RSDFCD2HVT } \\
        -lib_model_name RSDFCDHVT { -port CP UPF_GENERIC_CLOCK \\
                                    -port D ~UPF_GENERIC_DATA \\
                                    -port VDD sn1 \\
                                    -port TVDD retention_ref.power }
```

See Also

- set_retention
- set_retention_control

---

map_retention_clamp_cell

Specifies how to map or remap retention clamp cells belonging to the specified retention strategy.

Syntax

```
status map_retention_clamp_cell
{retention_strategies}
```

Feedback

```
-domain power_domain
[-lib_cells {UPF_GENERIC_CLOCK {lib_cells}}]
[-lib_cells {UPF_GENERIC_ASYNC_LOAD {lib_cells}}]
[-clock_clamp_lib_cells {lib_cells}]
[-async_clamp_lib_cells {lib_cells}]
```

Data Types

```
retention_strategies  list
power_domain          string
lib_cells             list
clock_clamp_lib_cells list
async_clamp_lib_cells list
```

Arguments

retention_strategy

Specifies the UPF retention strategy name. The retention strategy name should be unique within the specified power domain.

-domain *power_domain*

Specifies the power domain name that this UPF retention strategy will be applied to.

-lib_cells *lib_cells*

-clock_clamp_lib_cells *lib_cells*

-async_clamp_lib_cells *lib_cells*

Specifies a list of target library lib cells to be used for the retention clamp cell mapping. -lib_cells will be obsolete in future release, it can't be used together with -clock_clamp_lib_cells or -async_clamp_lib_cells option. -lib_cells with UPF_GENERIC_CLOCK or -clock_clamp_lib_cells specifies library cells must be used for mapping ZPR clamp cells on clock path. -lib_cells with UPF_GENERIC_ASYNC_LOAD or -async_clamp_lib_cells specifies library cells must be used for mapping ZPR clamp cells on async set/reset paths.

Description

This command defines how the retention clamp cells are mapped and implemented.

Examples

The following example maps retention clamp cells under the retention strategy retention_2 to HDBSVT16_NR2B_1 library cells on both clock and async set/reset path.

```
prompt> map_retention_clamp_cell retention_2 \\
        -domain PDM -lib_cells { UPF_GENERIC_CLOCK { HDBSVT16_NR2B_1 } }
 \\
     -lib_cells { UPF_GENERIC_ASYNC_LOAD { HDBSVT16_NR2B_1 } }
```

Feedback

```
prompt> map_retention_clamp_cell retention_2 \\
        -domain PDM -clock_clamp_lib_cells { HDBSVT16_NR2B_1 } \\
     -async_clamp_lib_cells { HDBSVT16_NR2B_1 }
```

See Also

- set_retention
- set_retention_control

---

mark_clock_trees

Marks clock attributes on clock objects.

Syntax

status *mark_clock_trees*

```
[-clocks clock_list]
[-clear]
[-synthesized | -dont_touch | -routing_rules]
[-net_type]
[-clock_cell_spacing]
[-fix_sinks]
[-freeze_routing]
```

Data Types

clock_list	collection

Arguments

`-clocks clock_list`

Marks only the clock trees specified in *clock_list*. By default, the command marks for all currently defined clocks in all active modes.

`-clear`

Removes the attributes on clock objects. If no option other than *-clear* is specified, then tool will remove clock synthesized attributes on clock objects. If the *-dont_touch* option is specified, the tool will remove the dont_touch atrribute on clock objects. Similarly, if any other options are specified together with this option, the tool will clear attributes or settings that the other options are supposed to set on the clock objects.

`-synthesized`

Marks clock synthesized attributes on clock objects, including cells and nets in the clock trees. On clock nets the net_type attribute updated as clock.

Feedback

The dont_touch attribute for CTS reason is also marked on clock nets. On clock network cells physical_status attribute set as application fixed. On sinks cts_size_in_place attribute set to true. This option cannot be used together with *-dont_touch*, *-routing_rules* and *-net_type*.

`-dont_touch`

Sets dont_touch attribute on clock objects, including cells and nets in the clock trees. This option cannot be used together with *-synthesized*, *-routing_rules* and *-net_type*.

`-routing_rules`

Propagates the non-default routing rules according to the settings of clock routing rules by *set_clock_routing_rules* command. This option cannot be used together with *-synthesized* and *-dont_touch*.

`-net_type`

Sets net type to clock on each hierarchical segment of each clock tree net. This option cannot be used together with *-synthesized* and *-dont_touch*.

`-clock_cell_spacing`

Propagates the clock cell spacing to the clock cells according to the rules specified by *set_clock_cell_spacing* command.

`-fix_sinks`

Marks clock sink as fixed placement in order to avoid subsequent commands sizing or moving them.

`-freeze_routing`

Marks synthesized net as locked and dont_touch in order to avoid routing of net by subsequent commands. This option cannot be used together with *-routing_rules*.

Description

This command marks clock attributes on clock objects to prevent the subsequent optimization programs to modify the built clock trees. Since the *synthesize_clock_trees* command automatically marks attributes on clock objects, the motivation of this command is for the third party tools. Default behavior of mark_clock_trees is "synthesized" mode.

Examples

The following example assumes a clock tree clk1 synthesized by a third party tool. After *mark_clock_trees*, this clock tree can then be recognized by the optimization programs.

```
prompt> mark_clock_trees
```

Feedback

In the following example, default behavior of clear option is shown. It will only clear settings done by "synthesized" mode.

```
prompt> mark_clock_trees -clear
```

See Also

- synthesize_clock_trees
- set_clock_cell_spacing

---

mark_failsafe_fsm

Creates one failsafe FSM group.

Syntax

status *mark_failsafe_fsm*

```
[-rule failsafe_fsm_rule]
[-name group_name]
[-registers pins]
[-parity pins]
[-synchronizer pins]
[-error_signal pin_or_port]
[-taps cells]
[-correction_signal pin_or_port]
[-requirement_id requirement_id]
[-encoder cell]
[-decoder cell]
[-update]
[-split_pins pins]
```

Data Types

failsafe_fsm_rule	collection
group_name	string
pins	collection
pin_or_port	collection
cells	collection
cell	collection
requirement_id	string
pins	collection

Arguments

`-rule failsafe_fsm_rule`

Specifies the failsafe FSM rule, based on which this failsafe FSM group should be created. This is mandatory, if the *-update* option is not specified.

Feedback

`-name` *group_name*

Specifies the name of the new failsafe FSM group. If not specified, the tool automaticaly generates the name.

`-registers` *pins*

Specifies the collection of register output pins, which is part of the failsafe FSM group. This is mandatory, if the *-update* option is not specified.

`-parity` *pins*

Specifies the collection of output pins of registers, which are parity registers for the failsafe FSM group. This is mandatory, if the *-update* option is not specified.

`-synchronizer` *pins*

Specifies the collection of output pins of registers, which are the synchronizer registers for the failsafe FSM group.

`-error_signal` *pin_or_port*

Specifies an existing pin or port in the design to which the error signal generated from the failsafe finite state machine logic should be tied. Either a hierarchical or leaf-level pin or an output port can be specified, but it must exist in the design. This is mandatory for the rules of encoding type *hamming2*. It cannot be specified for the rules of encoding type *hamming3*.

`-taps` *cells*

Specifies the collection of tap cells for this group.

`-correction_signal` *pin_or_port*

Specifies the pin or port in the design where all the correction outputs are connected to. Either a hierarchical or top-level port or input pin of leaf-level cell can be specified, but it must exist in the design. This is optional. It cannot be specified for the rules of encoding type *hamming2*.

`-encoder` *cell*

Specifies the hierarchical or leaf-level cell, which is the encoder logic for this group. This is optional.

`-decoder` *cell*

Specifies the hierarchical or leaf-level cell which is the decoder logic for this group. This is optional.

`-requirement_id` *requirement_id*

Specifies the requirement Id string for tracking in requirement management system. The requirement Id string should only contains either alphanumeric, underscore or hyphen characters.

Feedback

`-update`

Specifies that the existing failsafe_fsm_group that needs to be updated. The *-name* must be specified and the group with that name must exist.

The following attributes of the group can be updated: *synchronizer*, *taps*, *error_signal*, *correction_signal*, *encoder*, *decoder*, *requirement_id* and *split_pins*.

This option is mutually exclusive with *-rule*, *-registers* and *-parity*.

`-split_pins` *pins*

Specifies the set of pins, which should be split to be a part of different branches of high-fanout tree. This is optional.

Description

This command creates one failsafe FSM group object based on the given parameters. It stores the reference to the original failsafe FSM rule, which was honored to create it. This command supports undo or redo operations.

This command is primarily used for manually created failsafe finite state machines. You can manually create failsafe finite state machines in the design and mark them appropriately for further analysis down the flow.

You can choose two different approaches for this: RTL based flow, and Netlist based flow.

For both the flows, ensure that failsafe finite state machine has been already synthesized. In RTL based flow, the synchronizer and parity registers can be included in the RTL itself. After linking the design using the *set_top_module* command, the *mark_failsafe_fsm* command can be used, and these registers can be specified with it. In other words, the failsafe finite state machine should be implemented at RTL level. In the netlist based flow, you can start with a design, where finite state machines are present (this can be verified by running the *report_rtl* command first). Note that netlist creation using the *read_verilog* does not work for this flow, since the RTL must go through the *analyze* and *elaborate* steps to process the finite state machines. You can instantiate the synchronizer and parity registers manually using a command such as *create_cell* and manually perform the encoding and connections in the netlist. After that, the *mark_failsafe_fsm* command can be called to mark it as a failsafe finite state machine.

Examples

The following example creates a failsafe FSM group consisting of three registers, a correction signal and requirement Id:

```
prompt> mark_failsafe_fsm -rule rule1 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -correction_signal {correction_port} \\
    -requirement_id cff_group-1 -name group1
```

Feedback

The following example creates a failsafe FSM group with synchronizer and error_signal:

```
prompt> mark_failsafe_fsm -rule rule2 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -synchronizer {flop5/Q} -error_signal {err_port} -name group2
```

The following example creates a failsafe FSM group consisting of tap cells and split_pins:

```
prompt> mark_failsafe_fsm -rule rule3 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -taps {TAP1 TAP2} -split_pins {flop1/pin1 flop2/pin2} -name group3
```

The following example updates the taps and error_signal attributes of existing failsafe_fsm_group group3.

```
prompt> mark_failsafe_fsm -update -name group3 \\
    -taps {TAP3 TAP4} -error_signal err_blk/IN1
```

See Also

- get_failsafe_fsm_groups
- remove_failsafe_fsm_groups
- report_failsafe_fsm_groups

---

mark_safety_core

Creates one safety_core_group object.

Syntax

status *mark_safety_core*

```
[-rule safety_core_rule]
[-cores core_specifiers]
[-name group_name]
[-logic cells]
[-error_signal pin_or_port]
[-split_pins pins]
[-taps cells]
[-correction_signal pin_or_port]
[-requirement_id requirement_id]
[-control_groups control_group_list]
[-signal_mapping port_name_signal_pair_list]
[-delay_cells cells]
[-update]
```

Data Types

safety_core_rule	collection
core_specifiers	list

Feedback

```
group_name                  string
cells                       collection
pin_or_port                 collection
pins                        collection
requirement_id              string
control_group_list          list
port_name_signal_pair_list  list
```

Arguments

`-rule` *safety_core_rule*

Specifies the safety core rule-based on which this safety core group is created. This is mandatory, if the *-update* option is not specified.

`-cores` *core_specifiers*

Specifies the list of safety cores, which should be part of this safety core group. A core_specifier can have one of the two possible types:

```
1. cell type : single hierarchical cell name
2. group type : a list of non-nested hierarchical cell names
 between {}; For example {H1 H2}, H1 cannot (indirectly) contain
 H2 or vice versa.
```

In other words, either a list of logical hierarchical cells (cell type) or a list of lists of non nested hierarchical cells (group type) must be specified as the cores.

Each of the listed hierarchical cells for the cores must be mutually exclusive. The group type does not allow direct specification of leaf cells. It only allows specification of hierarchical cells. If any leaf cell is specified, the command issues an error message.

This option is mandatory, if the *-update* option is not specified.

`-name` *group_name*

Specifies the name of the new safety_core_group object. If the option is not specified, the tool automatically generates the name.

`-logic` *cells*

Specifies the collection of logic cells, which form a part of the voting logic circuit. These must be combinational cells.

`-error_signal` *pin_or_port*

Specifies the pin or port by which compare error are connected.

`-split_pins` *pins*

Specifies the set of pins, which should be split so as to be a part of different branches of high-fanout tree.

Feedback

`-taps` *cells*

Specifies the collection of tap cells for the cores in this group.

`-correction_signal` *pin_or_port*

Specifies an existing pin or port in the design to which all the correction outputs are connected to. This is optional. Either a hierarchical or top-level port or an input pin of a leaf-level or hierarchical cell can be specified, but it must exist in the design.

`-requirement_id` *requirement_id*

Specifies the requirement Id string for tracking in requirement management system. The requirement Id string should only contains either alphanumeric, underscore or hyphen characters.

`-control_groups` *control_group_list*

Specifies the list of control groups. This is optional. If specified, all the cores should have same reference module. All the ports of the specified control groups should exist on the reference module of the core otherwise the command issues an error message.

`-signal_mapping` *port_name_signal_pair_list*

Specifies the list of pairs, where {port_name signal} specified that the pin of the wrapper designated by port_name must connect to the specified signal in its context. This is optional.

`-delay_cells` *cells*

Specifies the instances or cells which have been introduced with delay.

`-update`

Specifies that the existing safety_core_group that needs to be updated. The *-name* must be specified and the group with that name must exist.

The following attributes of the group can be updated: *logic*, *error_signal*, *split_pins*, *taps*, *correction_signal*, *requirement_id*, *control_groups*, *signal_mapping*, and *delay_cells*.

This option is mutually exclusive with the *-rule* and *-cores* options.

Description

This command creates one safety_core_group object based on the given parameters. It stores the reference to the original safety core rule, which was honored to create it.

Feedback

Examples

The following example creates a safety_core_group object consisting of two cell type cores and some voting logic combinational cells.

```
prompt> mark_safety_core -rule rule1 \\
    -cores {cntrl alu} \\
    -logic {Iand1 Iand2 Ixor1} \\
    -error_signal Err_out \\
    -correction_signal corr_blk/IN1 \\
    -name group1
```

The following example creates a safety_core_group object consisting of two cell type cores, tap cells and requirement Id.

```
prompt> mark_safety_core -rule rule2 \\
    -cores {cntrl alu} \\
    -taps {TAP1 TAP2} \\
    -logic {Iand1 Iand2 Ixor1} \\
    -requirement_id csc_group-2 \\
    -name group2
```

The following example updates the split_pins, error_signal, logic and taps attributes of existing safety_core_group group2.

```
prompt>  mark_safety_core -update -name group2 \\
    -split_pins {flop/Q} \\
    -error_signal err_blk/IN1 \\
    -logic {Iand1} \\
    -taps {TAP3 TAP4}
```

The following example creates a safety_core_group object consisting of two group type cores that is {H1 H2} and {H3 H4 H5}, control groups , delay cells, and signal_mapping.

```
prompt>  mark_safety_core -rule rule2 \\
    -cores { {H1 H2} {H3 H4 H5} } \\
    -control_groups { control_group1 control_group2 } \\
    -signal_mapping {{clk clock} \{dcls_clk dcls_clock}} {rst reset}
 {clock1 c1s}} \\
    -delay_cells {cell1 cell2} -name group3
```

See Also

- get_safety_core_groups
- remove_safety_core_groups
- report_safety_core_groups

Feedback

mark_safety_error_code

Creates one safety_error_code_group object.

Syntax

status *mark_safety_error_code*

```
[-rule safety_error_code_rule]
[-name group_name]
[-data pins_or_ports]
[-checkbits pins_or_ports]
[-error_signal pin_or_port]
[-correction_signal pin_or_port]
[-taps cells]
[-update]
[-encoder cell]
[-decoder cell]
[-requirement_id requirement_id]
[-split_pins pins]
```

Data Types

safety_error_code_rule	collection
group_name	string
pins_or_ports	collection
pin_or_port	collection
cells	collection
cell	collection
requirement_id	string
pins	collection

Arguments

`-rule` *safety_error_code_rule*

Specifies the safety_error_code_rule based on which this safety_error_code_group should be created. This is mandatory option, if *-update* option is not specified.

`-name` *group_name*

Specifies the name of the new safety_error_code_group object. If not specified, the tool generates the name for the safety_error_code_group object.

`-data` *pins_or_ports*

Specifies the collection of pins or ports of data signal to be encoded or decoded for this safety_error_code_group. This is mandatory option, if *-update* option is not specified.

Feedback

`-checkbits` *`pins_or_ports`*

Specifies the collection of pins or ports, where the checkbits from the encoder output are connected for this safety_error_code_group. This is mandatory option, if *-update* option is not specified.

`-error_signal` *`pin_or_port`*

Specifies the existing pin or port in the design to which the decoder error output is connected to. This is mandatory option for rules of encoding type *edc*, *even_parity* or *odd_parity*. It cannot be specified for rules of encoding type *ecc*.

`-correction_signal` *`pin_or_port`*

Specifies the existing pin or port in the design to which the decoder correction output is connected to. This can be specified for rules of encoding type *ecc* and when the mode is either decode or encode_decode. This is optional. It cannot be specified for rules of encoding type *edc*, *even_parity* or *odd_parity*.

`-taps` *`cells`*

Specifies the collection of tap cells for this group.

`-update`

Specifies that the existing safety_error_code_group that needs to be updated. The *-name* must be specified and the group with that name must exist.

The following attributes of the group can be updated: *taps*, *error_signal*, *correction_signal*, *requirement_id*, and *split_pins*.

This option is mutually exclusive with *-rule*, *-data*, *-checkbits*, *-encoder* and *-decoder*.

`-encoder` *`cell`*

Specifies the hierarchical or leaf-level cell which is the encoder logic for this group. This is mandatory option, if *-update* option is not specified.

`-decoder` *`cell`*

Specifies the hierarchical or leaf-level cell which is the decoder logic for this group. This is mandatory option, if *-update* option is not specified.

`-requirement_id` *`requirement_id`*

Specifies the requirement Id string for tracking in requirement management system. The requirement Id string should only contains either alphanumeric, underscore or hyphen characters.

`-split_pins` *`pins`*

Specifies the set of pins, which should be split to be a part of different branches of high-fanout tree. This is optional.

Feedback

Description

This command creates one safety_error_code_group object based on the given parameters. It stores the reference to the original safety_error_code_rule, which was honored to create it. This command supports undo or redo operations. The command shows error, if the *data* or *checkbits* pins or ports list is empty. The command shows error, if any of the *data* or *checkbits* pins or ports belong to existing safety error code groups. In the list, all elements should be either pin or port, combination of pins and ports in the list is not allowed.

Examples

The following example creates a safety_error_code_group object with data, checkbits pins, a correction signal and requirement Id.

```
prompt> mark_safety_error_code -rule rule1 \\
    -data {cell_1/pin1 cell_1/pin2 cell_1/pin3 cell_1/pin4} -checkbits
 {cell_2/pin} \\
    -encoder {encoder_cell} -decoder {decoder_cell} \\
    -correction_signal {correction_port} \\
    -requirement_id csec_group-1 \\
    -name group1
```

The following example creates a safety_error_code_group object with error_signal

```
prompt>  mark_safety_error_code -rule rule1 \\
    -data {cell_3/pin1 cell_3/pin2 cell_3/pin3 cell_3/pin4} -checkbits
 {cell_4/pin} \\
    -error_signal {err_port} -encoder {encoder_cell} -decoder
 {decoder_cell} \\
    -name group2
```

The following example creates a safety_error_code_group object consisting of tap cells and split_pins.

```
prompt> mark_safety_error_code -rule rule2 \\
    -data {cell_5/pin1 cell_5/pin2 cell_5/pin3 cell_5/pin4} -checkbits
 {cell_5/pin} \\
    -taps {TAP1 TAP2} -encoder {encoder_cell} -decoder {decoder_cell}\\
    -split_pins {cell_5/pin5 cell_4/pin1}\\
    -name group3
```

The following example updates the taps and error_signal attributes of existing safety_error_code_group group3.

```
prompt> mark_safety_error_code -update -name group3 \\
    -taps {TAP3 TAP4} \\
    -error_signal err_blk/IN1
```

---

mark_safety_register

Creates one safety register group.

Syntax

status *mark_safety_register*

```
[-rule safety_register_rule]
[-name group_name]
[-registers objects]
[-logic cells]
[-taps cells]
[-split_pins pins]
[-error_signal pin_or_port]
[-correction_signal pin_or_port]
[-requirement_id requirement_id]
[-update]
```

Data Types

safety_register_rule	collection
group_name	string
objects	collection
cells	collection
pins	collection
pin_or_port	collection
requirement_id	string

Arguments

`-rule` *safety_register_rule*

Specifies the safety register rule, based on which this redundancy group is created This is mandatory option, if *-update* option is not specified.

`-name` *group_name*

Specifies the name of the new safety register group. If not specified, the name is automatically generated by the tool.

`-registers` *objects*

Specifies the collection of registers or register output pins, which should be part of this register redundancy group.

Feedback

`-logic` *cells*

Specifies the collection of logic cells, which form a part of the voting logic circuit. These must be combinational cells. They can either be hierarchical cells or leaf-level cells.

`-taps` *cells*

Specifies the collection of tap cells for the registers in this group.

`-split_pins` *pins*

Specifies the set of pins, which should be split so as to be a part of different branches of high-fanout tree.

`-error_signal` *pin_or_port*

Specifies an existing pin or port in the design to which the error signal generated from voting logic should be tied. Either a hierarchical or leaf-level pin or an output port can be specified, but it must exist in the design. This is mandatory option for rules of type *dual_mode*. It cannot be specified for rules of type *fault_tolerant* or *triple_mode*.

`-correction_signal` *pin_or_port*

Specifies an existing pin or port in the design to which all the correction outputs are connected to. This is optional. Either a hierarchical or top-level port or an input pin of a leaf-level or hierarchical cell can be specified, but it must exist in the design. It cannot be specified for rules of type *dual_mode* or *fault_tolerant*.

`-requirement_id` *requirement_id*

Specifies the requirement Id string for tracking in requirement management system. The requirement Id string should only contains either alphanumeric, underscore or hyphen characters.

`-update`

Specifies that the existing safety register group that needs to be updated. The *-name* must be specified and the group with that name must exist.

The following attributes of the group can be updated: *registers*, *logic*, *taps*, *split_pins*, *error_signal*, *correction_signal*, and *requirement_id*.

This option is mutually exclusive with *-rule*.

Description

This command creates one safety register group based on the given parameters. It stores the reference to the original safety register rule, which was honored to create it.

Feedback

Examples

The following example creates a safety_register_group object consisting of 3 registers, some voting logic combinational cells and requirement Id.

```
prompt> mark_safety_register -rule rule1 \\
    -registers {flop1 flop2 flop3} \\
    -logic {Iand1 Iand2 Ixor1} \\
    -requirement_id csr_group-1 \\
    -name group1
```

The following example creates a safety_register_group object consisting of 3 register output pins, tap cells and correction signal.

```
prompt> mark_safety_register -rule rule2 \\
    -registers {flop1/Q flop2/Q flop3/Q} \\
    -taps {TAP1 TAP2} \\
    -correction_signal corr_blk/IN1 \\
    -name group2
```

The following example creates a safety_register_group object consisting of 2 register output pins and error signal.

```
prompt> mark_safety_register -rule dmr1 \\
    -registers {flop1/QN flop2/QN} \\
    -error_signal err_blk/IN1 \\
    -name group2
```

The following example updates the taps, registers, logic and error_signal attributes of existing safety register group group2.

```
prompt>  mark_safety_register -update -name group2 \\
    -taps {TAP3 TAP4} \\
    -registers {flop4/QN flop5/QN} \\
    -logic {Iand1} \\
    -error_signal err_blk/IN2
```

- write_safety_register_script

---

mem

Retrieves the total memory allocated by the current process.

Feedback

Syntax

int *get_mem*

Description

The *get_mem* command returns the size of memory currently allocated by the current process for the purposes of storing design netlist, design annotations, and constraints information as well as computed timing information. The value printed represents the amount in kilobytes (kB).

Note that the value reported would not match values obtained by the user through Unix process tracking commands, such as *top*. This is the case because the *get_mem* command does not track memory used to load the executable and maintain process stack space. Also, it does not differentiate between resident and swapped memory.

```
prompt> get_mem
8092
```

See Also

- get_cputime

---

merge_abstract

Merges changes made to the current design's abstract view into the full design view.

Syntax

```
status merge_abstract
[-blocks block_designs]
[-all_blocks]
[-host_options host_option_name]
[-force]
```

Data Types

block_designs list *host_option_name* string

Arguments

`-blocks block_designs`

Specifies the list of child block designs on which to perform merge. This option is mutually exclusive with *-all_blocks*. If the *-blocks* or *-all_blocks* options are not specified, the command merges the current design.

Feedback

`-all_blocks`

Merges abstracts for all the child block instances in the current design. This option is mutually exclusive with *-blocks*. If the *-blocks* or *-all_blocks* options are not specified, the command merges the current design.

`-host_options` *`host_option_name`*

Specifies the name of the host option to use for distributed processing. When *-blocks* or *-all_blocks* is specified, the tool might need to perform merge for more than one block. Some of the blocks can run at the same time, depending on the hierarchy nesting.

`-force`

Merges changes to the abstract view for the current design into the full design view, regardless of the current state of the views.

Description

This command updates the full netlist design view for the current design with any changes made to the abstract view.

Use the *merge_abstract* command to keep the design view representation up-to-date. After running *merge_abstract*, you can immediately run the *create_abstract* command to generate a new abstract view from the up-to-date design view, or you can perform other operations before creating a new abstract view.

This command merges any changes to the abstract view into the design view. Possible changes include: netlist modification, boundary shape change, cell location change, newly created or deleted objects, objects pushed down from higher level of physical hierarchy, and so on.

By default, abstracts created with *create_abstract* can be edited. That is, you can open the abstract in edit mode and make changes. Changes can be merged back into the full netlist design by using the *merge_abstract* command.

Design Flow for Editable Abstracts

When you create an editable abstract (the default), it is assumed that you will eventually run *merge_abstract* after editing the abstract. The *merge_abstract* command requires that the full netlist design remain unchanged between the time that the abstract is created with the *create_abstract* command and the abstract is merged with the *merge_abstract* command.

Because the netlist should not be changed, the *create_abstract* command marks the full netlist as read-only until after running the *merge_abstract* command. After you run *merge_abstract*, the open blocks that depend on the abstract are automatically upgraded to "edit" mode.

Feedback

Examples

The following example opens the design view of CHIPTOP and merges the changes to the abstract view back to the design view of design CHIPTOP.

```
prompt> open_block CHIPTOP.design
prompt> merge_abstract
```

---

merge_clips

Merges a set of clip blocks.

Syntax

int *merge_clips*

```
[-clip_library lib]
[-block block]
[-clip_blocks blocks]
[-verbose]
[-force_reset]
```

Data Types

```
lib       library
block     design
blocks    list of designs
```

Arguments

`-clip_library lib`

Specifies a clip library from which all valid clip blocks are merged. This is an optional option.

`-block block`

Specifies the source block for the merge operation. If you do not provide this option, the command operates on the current block. This is an optional option.

Feedback

`-clip_blocks` *blocks*

Applies the merge operation to a subset of blocks in the specified clip library. This is an optional option.

`-verbose`

Enables detailed reporting of the merge operation, including identified merge conflicts, data inconsistencies, and other relevant information. This is an optional option.

`-force_reset`

Marks the merge process as complete for the given source block. This is an optional option.

Description

The *merge_clips* command takes the clip blocks in a given library and updates the corresponding regions in the target block to reflect edits made in the clip blocks. The merge process follows a set of basic rules, and does not support many possible edits of the clip block. The merge rules are as follows:

- Any surviving objects from the clip block have their physical geometry (specified below) updated in the source block
  - Origin
  - Orient
  - Boundary
  - Mask constraint
- Any objects deleted from the clip block are deleted in the source block
- Any objects created in the clip block are added in the source block

The objects referred to in the previously specified merge rules consist of the objects copied into the clip block with the exception of hierarchical fill shapes. Hierarchical fill shapes are present in clip blocks for context, but any edits made to them are not preserved in the merge process. The tool places no restrictions on the editing of clip blocks, but as the previously specified merge rules imply, many edit operations are not preserved through the merge. For example, you might place all the objects in the clip block into a group, but the merge operation neither creates a new group in the source block nor preserves the group-related attributes of the objects.

The merge process does not honor any logical edits made in clip blocks. For example, remastered instances and re-netted connections do not result in any updates to the source block post merge.

Feedback

The merge process can operate on any number of clip blocks at the same time, and a block might undergo a merge process any number of times. However, merging yields the best results when all relevant clip blocks are specified in a single merge command, as the source block does not save any form of version history to support three way merges. Furthermore, you can only merge a given clip once, and the state change of a clip from active to resolved is a one-way transition. You cannot roll back the clip to a 'has not yet been merged' state.

Merge Conflicts:

Because clips contain all objects that intersect the clip region, a given object might appear in multiple clips. In such a case, the order in which the clip blocks merge back into the source block determines the final state of the object.

Examples

The following command merges the clip blocks contained in myLib into the current block:

```
prompt> merge_clips -clip_library $myLib
```

The following command resolves the merge status for the current block:

```
prompt> merge_clips -force_reset
```

See Also

- create_clips
- report_active_clips

---

merge_clock_gates

Merges ICG cells in clock trees.

Syntax

status *merge_clock_gates*

```
[-clocks clock_list]
```

Data Types

clock_list	list

Arguments

`-clocks clock_list`

Merges ICG cells only in the clock trees specified in *clock_list*. By default, the command merges ICG cells for all currently defined clocks in all active modes.

Feedback

Description

This command merges ICG cells in each clock tree without affecting the logic of the design. The merged ICG cells have the same type and their enable pins have the same logic.

Examples

The following example merges ICG cells in the specified clock tree.

```
prompt> merge_clock_gates -clocks clk1
```

---

merge_objects

Merges shapes of the specified objects.

Syntax

status *merge_objects*

```
[object_list]
[-attributes attribute_list]
[-connections]
[-merge_type type]
[-quiet]
```

Data Types

```
object_list       string or collection
attribute_list    list of attribute names
type  string
```

Arguments

object_list

Specifies a collection or selection set containing objects to merge. If this option is not specified, the global selection set is used.

`-attributes` *attribute_list*

Specifies additional list of attributes which need to match in order to merge two shapes. By default merge happens when *object_class*, *layer*, *shape_use* and *owner* attributes match.

Note: The additional attribute are being compared by the string values.

`-connections`

If specified collection or selection set contains shapes and vias, lookup for the first level connections to merge with.

Feedback

`-merge_type` *type*

Specifies which merge type will be performed: *object* or *polygon*. The default value is *object* for requiring the objects to be merged have the same *object_class* type (and the same *shape_type* for object_classs *shape*; rect and polygon however will be treated as the same); *polygon* type is used only in the case of object_classs *shape*, which ignores the *shape_type* attribute and merges all selected shapes into a polygon.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

Description

This command merges specified object shapes; all fixed objects are skipped. The following objects are supported: move bound shapes, voltage area shapes, corridor shapes, net shapes, pin shapes, site rows, and site arrays.

Snapping is not performed as it is assumed that the shapes are already correct.

Note that only interconnected net shapes that belong to the same net, are on the same metal layer, and have the same width and end type can be merged. Nonrectilinear ending segments of a path are not merged.

The command returns a collection of the merged objects if the specified *object_list* is a collection of objects. Otherwise the command modifies objects in specified selection set and returns status.

Examples

The example merges two shapes to a single shape.

```
prompt> merge_objects
```

The alternative syntax uses collection to specify objects.

```
prompt> merge_objects [get_selection]
```

This syntax can merge a path and a polygon shape into one polygon.

```
prompt> merge_objects -merge_type poylgon
```

---

merge_pg_mesh

Merges overlapped wires of PG nets after the PG mesh is created.

Syntax

status *merge_pg_mesh*

```
[-nets netname_list]
[-types type_list]
[-layers layer_list]
[-shapes shape_list]
[-tag ag_name]
[-undo]
```

Data Types

```
netname_list      list
type_list         list
layer_list        list
shape_list        list
tag_name          string
```

Arguments

`-nets net_list`

Specifies a list of PG nets on which to merge wires. By default, all PG nets are processed.

`-types type_list`

Specifies a list of PG object types. The PG types should include one or more of the following keywords: *stripe*, *ring*, *macro_pin_connect*, *lib_cell_pin_connect*, *follow_pin*, *core_wire*, and *user_route*. These types are for PG stripes, PG rings, macro pin connections, standard cell pin connections, follow pins wires, core wires and user route wires. By default, all of these types are considered for wire merging.

`-layers layer_list`

Specifies metal layer names for the PG objects. *layer_list* is a list containing layer names. By default, objects on all metal layers are considered for wire merging.

Feedback

`-shapes` *`shape_list`*

Specifies a list of PG shapes for which to merge wires. By default, only top-level wires of PG nets will be merged.

`-tag` *`tag_name`*

Specifies a tag name to assign to all merged shapes created within this merge process. This tag name is used as contents of a user attribute tag for filtering collections at later stages. By default, no tags are assigned.

`-undo`

Restores merged shapes to their original objects that merged by most recent *merge_pg_mesh* command. Only one level of undo is supported. The *merge_pg_mesh -undo* command clears the undo command stack.

Description

This command performs PG wire merging after the PG mesh is created for the whole design. The command is use to reduce PG wire objects without changing wire shape geometry. The command only merge rectangle shapes. If the two overlapped shapes cannot form a new rectangle, they won't be merged. The *merge_pg_mesh* command only merges wire shapes on top-level. After *merge_pg_mesh*, one level undo is supported for user to recover original shapes.

Examples

The following example performs PG wire merging on all PG nets. after PG mesh is created.

```
prompt> merge_pg_mesh
```

The following example performs PG wire merging with some constraints. Only wire shapes with those attribute are process.

```
prompt> merge_pg_mesh \\
    -nets {VDD VSS} \\
    -types {stripe lib_cell_pin_connect} \\
    -layers M5
```

- set_pg_strategy

---

merge_stream

Merges multiple GDSII or OASIS stream files to a single stream file.

Syntax

```
status merge_stream
[-format output_format]
[-rename_cell cell_renaming_file]
[-merge_cell_shapes]
[-rename_conflicting_cell]
[-merge_conflict_suffix suffix_string]
[-merge_adding]
[-compress_gds]
[-oasis_compression_level level]
[-cell_log_file cell_log_file]
[-units value]
[-top_cell cell_name]
[-verbose]
-merge_files file_names
output_file
```

Data Types

output_format	string
cell_renaming_file	string
suffix_string	string
level	integer
cell_log_file	string
value	double
cell_name	string
file_names	list of strings
output_file	string

Arguments

`-format output_format`

Specifies the output file format, either *gds* for GDSII or *oasis* for OASIS. The default is *gds*.

`-rename_cell cell_renaming_file`

Specifies the file that contains the mapping from original cell names to new cell names. For the renaming file format, see the DESCRIPTION section. The

Feedback

renaming works for both leaf-level library cells and macros. By default, the merging process keeps the original cell names.

`-merge_cell_shapes`

Specifies that the shapes from identically named cells in different source files are to be merged into a single cell in the output file. The first source file must contain all the cells' structure definitions. If one cell's structure definition is not included in the first source file, it will not be merged into the output file. By default, while reading the source files, the command overwrites any previous cell of the same name, without performing any merging or renaming of the conflicting cells.

`-rename_conflicting_cell`

Specifies that identically named cells in different source files are to be renamed to avoid conflict. The first cell read in keeps its original name. Any subsequent cells with the same name are renamed by appending a string and then written to the output file as separate cells. The default strings appended are _R, _R1, _R2, and so on. By default, while reading the source files, the command overwrites any previous cell of the same name, without performing any merging or renaming of the conflicting cells.

`-merge_conflict_suffix` *`suffix_string`*

Specifies the suffix string used with the *-rename_conflicting_cell* option. The string can be up to 10 characters and may contain letters, numerals, dollar signs ($), and underscore characters. The default suffix is "_R".

`-merge_adding`

Specifies the merge mode as adding. It combines the top cells in the source files to the top cell of the first source file, resolves conflicts for the child cells by adding cell name prefix. The output file will have exactly one top cell. By default, while reading the source files, the command overwrites any previous cell of the same name, without performing any merging or renaming of the conflicting cells.

`-compress_gds`

Writes out the GDSII file in gzip compressed format. By default, the output GDSII file is written as uncompressed plain text.

`-oasis_compression_level` *`level`*

Writes out the OASIS file in compressed format using the specified compression level, an integer between 1 and 9. By default, the output OASIS file is not compressed. This option has an effect only if the *-format* option is set to *oasis*.

`-cell_log_file` *`cell_log_file`*

Specifies the name of a cell log file. The command writes out the names of the processed cells into this file.

Feedback

`-units` *value*

Specifies the database unit size for the output stream file. The default is 1e-09 (nanometer units).

`-top_cell` *cell_name*

The top cell considered in the merge flow. The command merges only the specified cell and the cells in its hierarchy. All other cells are omitted from the output file. By default, the command writes out all cells in the input files.

`-verbose`

Generates detailed system messages during stream merging.

`-merge_files` *file_names*

Specifies the names of the input stream files to be merged. You can specify both GDSII and OASIS files as input.

output_file

Specifies the name of the output file generated by merging the input files.

Description

This command merges multiple GDSII/OASIS stream files into a single stream file in GDSII or OASIS format. You must specify at least the name of the stream files to be merged and the name of the new file generated by the merging process.

You can optionally specify the handling of identically named cells in different input files. By default, the last cell read in overwrites any earlier cells of the same name. Instead, you can merge the data in these cells (*-merge_cell_shapes*), or you can rename the cells to avoid conflict.

To rename cells, you can have a string automatically appended to each cell name (*-rename_conflicting_cell*). Alternatively, you can specify the new cell names explicitly in a file (*-rename_cell filename*), with each line in the file specifying the name mapping for a cell in the following format:

OldCellName NewCellName

For example, to rename the cell TOP to NEWTOP, enter the following line in the renaming file:

TOP NEWTOP

Feedback

Examples

The following example merges the colored macro named top.gds with the IP hard macros named HM1.gds and HM2.oasis:

```
prompt> merge_stream -format gds -units 1e-09 \\
  -merge_files {top.gds HM1.gds HM2.oasis} my_merge.gds
```

See Also

- write_gds
- write_oasis

---

merge_topology_plans

Syntax

```
merge_topology_plans
[-repeaters]
[-supernets]
[-verbose]

[topology plans]
```

Data Types

topology plans collection or list of names of topology plans to estimate *merge_topology_plans*.

Arguments

`-repeaters`

Only attempt to associate std cell register arrays with topology repeaters.

If neither *-repeaters* or *-supernets* is specified, both actions are attempted.

`-supernets`

Only attempt to create new supernet exceptions for topology plans with std cell repeaters or registers in the netlist for which supernet exceptions have not been created. Do not attempt to associate repeaters.

If neither *-repeaters* or *-supernets* is specified, both actions are attempted.

`-verbose`

Print additional information and actions taken at the end of processing each topology plan.

Feedback

Description

This command can be used to process topology plans after various actions that would invalidate them for further processing. For example, adding new std cell registers to the netlist that is associated to a topology plan, without adding new supernet exceptions, or associating those registers to topology repeaters.

The supernet exception creation operation scans the netlist from the terminals associated with the end(s) of a topology plan to the terminals associated with the start of that plan and records any register cell encountered. If any such cells do not have a corresponding supernet exception, one is created for that cell.

The repeater association operation scans the netlist from the terminals associated with the end(s) of a topology plan to the terminals associated with the start of that plan and records any register cell encountered. If any such cells are not associated with a topology repeater, and a valid un-associated topology repeater exists in the plan, the std cells are associated with the topology repeater.

By default (no arguments) both operations are performed: supernet exception creation, followed by repeater association. All specified topology plans are first processed for supernet creation, and then all specified topology plans are processed for repeater association.

To be able to correctly scan the netlist and find the correct registers cells to associated to the sequential topology repeaters, or correctly detect the missing supernet exceptions and update them, the input topology plan must have their topology nodes associated to correct block pins or top ports.

KNOWN LIMITATIONS

Currently, new topology repeaters are not created, only existing topology repeaters are assigned std cells.

---

modify_busplan

Modify various elements of a busplan.

Feedback

Syntax

```
int modify_busplan
[-add_guide]
[-add_register]
[-move_element element]
[-balance_registers]
[-remove_elements elements]
[-reconnect_elements elements]
[-change_rule rule]
[-after element]
[-before element]
[-location coord]
[-name element_name]
[-rename new_name]
[-load_launch_capture_budget]
[busplan]
```

Data Types

element	bus_element
elements	bus_elements
rule	bus_rule
coord	coordinate
element_name	string
new_name	string
busplan	busplan_name

Arguments

`-add_guide`

Adds a guide element to the bus plan.

`-add_register`

Adds a virtual register to the bus plan.

`-move_element` *element*

Changes the location of *element*. You must specify the *-location* option together with this option.

`-balance_registers`

Adds a minimal number of registers such that each branch of the busplan has the same number of registers. This only applies to busplans that have branches.

`-remove_elements` *elements*

Removes the specified elements from the busplan. It is an error to try to remove a start or end element of a busplan.

Feedback

`-reconnect_elements` *elements*

Removes and reconnects the path tree starting from *elements* to a new position in busplan. This is likely to change the topology of the bus plan. You must specify the *-after* option together with this option.

`-change_rule` *rule*

Specifies the net estimation rule to use.

`-after` *element*

Specifies the position in the bus to connect a newly created element with the *-add_guide* or *-add_register* options, or reconnect an existing element with the *-reconnect_elements* option.

`-before` *element*

Specifies the position in the bus to connect a newly created element with the *-add_guide* or *-add_register* option.

`-location` *coord*

Specifies the physical location for a newly created element with the *-add_guide* or *-add_register* options, or specifies a location for *-move_element*. This option is required when you specify *-move_element*.

`-name` *element_name*

Specifies the name for the newly created element. If not specified, a default name is created.

`-rename` *new_name*

Specifies a new name for the busplan.

`-load_launch_capture_budget`

Specifies to load the launch and/or capture budget from the current SDC constraints. This only works for top level ports on the busplan. The launch budget is gotten from the *set_input_delay* values on the starting elements of the busplan. The capture budget is gotten from the *set_output_delay* values on the ending elements of the busplan.

busplan

Specifies the busplan to be modified. This is required.

Description

This command changes the specified busplan. These changes include structural changes as well as placement changes.

Feedback

You must specify one of the following options to indicate the change required: *-add_guide*, *-add_register*, *-move_element*, *-remove_elements*, *-reconnect_elements*, or *-change_rule*.

Depending on the change required, other options then are required. See above for more details.

Examples

The following example creates a bus plan, then adds a virtual route pin to the bus plan.

```
prompt> create_busplans -name bus1 -from B1/OUT1[*] -start_end_cells {B1
 B2 B3 B4}
prompt> report_busplans bus1

****************************************

modify_die_area

Modify the boundary of the current design to change the size of the area.

Syntax

```
status modify_die_area
[ -area_scaling_factor scaling_factor ]
[ -height_scaling_factor scaling_factore ]
[ -width_scaling_factor scaling_factor ]
[ -fixed_edges list_of_sides ]
[ -core_utilization ratio ]
[ -sizing_type fixed_width | fixed_height | fixed_aspect_ratio ]
[ -compile ]
[ -run_track_creation_script script_file_name ]
[ -row_pattern row_pattern_name ]
```

Data Types

```
scaling_factor    float
list_of_sides     list of integers
ratio             float
script_file_name  string
row_pattern_name  string
```

Arguments

`-area_scaling_factor scaling_factor`

Specifies the scaling factor by which the core area has to resize. This option is mutually exclusive with -core_utilization, -height_scaling_factor, and -width_scaling_factor. 1 corresponds to 100% of the original size. Below 1 will shrink the die, above 1 will enlarge. The default is 1, so the command will use other options to determine the target die size.

`-height_scaling_factor scaling_factor`

Specifies the scaling factor by which the core height has to resize. This option is mutually exclusive with -core_utilization, -area_scaling_factor, and -sizing_type. 1 corresponds to 100% of the original size. Below 1 will shrink the die, above 1 will enlarge. The default is 1, so the command will use oether options to determine the target die size.

Feedback

`-width_scaling_factor` *`scaling_factor`*

Specifies the scaling factor by which the core width has to resize. This option is mutually exclusive with -core_utilization, -area_scaling_factor, and -sizing_type. 1 corresponds to 100% of the original size. Below 1 will shrink the die, above 1 will enlarge. The default is 1, so the command will use oether options to determine the target die size.

`-fixed_edges` *`list_of_edges`*

Specifies a list of edges whose length remains unchanged during die size exploration. By default, all chip or block boundary edges are scaled equally during die size exploration. Using this option, you can specify a list of edges whose length remains unchanged during die size exploration. The list_of_edges argument is a list of integers, where each integer represents an edge. Given any rectangular or rectilinear shape, the lower left-most edge is the starting edge with an edge number of 1. The number of the next edge, proceeding clockwise, is 2, and so on. The edges are numbered clockwise.

`-core_utilization` *`ratio`*

Specifies the desired utilization of the core area; range is beween 0 and 1. This option is mutually exclusive with -area_scaling_factor, -height_scaling_factor, -width_scaling_factor, and -sizing_type.

`-sizing_type` *`fixed_width`* | *`fixed_height`* | *`fixed_aspect_ratio`*

Defines constraints on the search space of aspect ratios. This option is mutually exclusive with -height_scaling_factor, -width_scaling_factor, and -core_utilization.

The arguments that can be provided to this option are

fixed_width - Keeps the horizontal dimension of the design a fixed dimension. When this argument is passed to the option "-sizing_type" the modify_die_area command only varies the y-dimension of the design during the estimation of the new die size.

fixed_height - Keeps the vertical dimension of the design a fixed dimension. When this argument is passed to the option "-sizing_type" the modify_die_area command only varies the x-dimension of the die during the estimation of the new die size.

fixed_aspect_ratio - Keeps the aspect ratio of the result equal to the aspect ratio of the original design. When this argument is passed to the option "-sizing_type" the modify_die_area command will maintain the aspect ratio of the input design. All the edges of the block (rectangular or rectilinear shape) will be scaled proportionally to maintain the aspect ratio.

Feedback

By default, the tool maintains the aspect ratio and allows the height and width to vary.

`-compile`

Option to implement the estimated die size by initializing a new floorplan layout and importing various key floorplan elements from the original floorplan. By default, the command only does calculations and prints the summary of the estimated floorplan layout including the new boundary co-ordinates, core area, width, height variation and more. Use this command option to proceed with the new floorplan implementation after examining the various statistics reported for the new die size.

`-run_track_creation_script` *`script_file_name`*

This option allows user to run custom track creation script specified by script_file_name.

`-row_pattern` *`row_pattern_name`*

Specifies the name of row pattern to be used for the floorplan when there are row pattern specifications in the physical rule section of the technology file.

Description

Calculates new die-area co-ordinates for the block based on user inputs, creates a floorplan based on the estimated coordinates and retains the characteristics of the original floorplan. It automatically maintains relative placement of hard macros, ports and optionally re-creates power network. It is recommended that you review the output before starting detailed implementation.

Examples

The following example shrinks core to 85% of its original size.

```
prompt> modify_die_area -area_scaling_factor .85
```

```
The following example shrinks core height only.
```

```
prompt> modify_die_area -heigh_scaling_factor .8
```

The following example shrinks core so that its utilization is 75%.

```
prompt> modify_die_area -core_utilization .75
```

See Also

- initialize_floorplan

Feedback

modify_rp_groups

Modifies relative placement group by adding, removing, swapping or flipping rows or columns.

Syntax

status *modify_rp_groups*

```
rp_group_list
-add_rows                row_number    number_of_rows     |
-add_columns             column_number number_of_columns  |
-remove_rows             row_number    number_of_rows     |
-remove_columns          column_number number_of_columns  |
-flip_row                row                              |
-flip_column             column                           |
-swap_rows               first_row     second_row         |
-swap_columns            first_column  second_column
```

Data Types

```
rp_group_list              list or collection
row_number                 integer
column_number              integer
number_of_columns          integer
number_of_rows             integer
row                        integer
column                     integer
first_row                  integer
second_row                 integer
first_column               integer
second_column              integer
```

Arguments

rp_groups_list

Specifies the relative placement groups that should be modified.

-add_rows *row_number number_of_rows*

Specifies two arguments to add new rows to relative placement group. The first argument is the row number where you want to add new rows and the second argument specifies the number of consecutive rows to be added.

-add_columns *column_number number_of_columns*

Specifies two arguments to add new columns to relative placement group. The first argument is the column number where you want to add new columns and the second argument specifies the number of consecutive columns to be added.

Feedback

`-remove_rows` *`row_number number_of_rows`*

Specifies two arguments to remove rows from relative placement group. The first argument is the row number where you want to remove rows and the second argument specifies the number of consecutive rows to be removed.

`-remove_columns` *`column_number number_of_columns`*

Specifies two arguments to remove columns from relative placement group. The first argument is the column number where you want to remove columns and the second argument specifies the number of consecutive columns to be removed.

`-flip_row` *`row`*

Specifies the row to be flipped. This option flips the objects in the row around the center of the row.

`-flip_column` *`column`*

Specifies the column to be flipped. This option flips the objects in the column around the center of the column.

`-swap_rows` *`first_row second_row`*

Specifies two rows of the specified relative placement group to be swapped. This option swaps the objects (cells, blockages, and hierarchical relative placement groups) of two specified rows.

`-swap_columns` *`first_column second_column`*

Specifies two columns of a relative placement group to be swapped. This option swaps the objects (cells, blockages and hierarchical relative placement groups) of two specified columns.

Description

This command modifies the structure of a specified relative placement group. You can add, remove, swap, or flip rows or columns of the specified relative placement group. If after modification, the location for *rp_location* anchor corner is empty then anchor corner will be removed from relative placement group.

Examples

The following example adds 3 new columns to all existing top-level relative placement groups at column position 0.

```
prompt> modify_rp_groups  [get_rp_groups -top] -add_columns {0 3}

1
```

The following example flips the first row of all top-level relative placement groups.

Feedback

```
prompt> modify_rp_groups [get_rp_groups -top] -flip_row 0
1
```

The following example swaps the first and second columns of the my_rp_group relative placement group:

```
prompt> modify_rp_groups [get_rp_groups my_rp_group] -swap_columns {0 1}
1
```

The following example removes 2 rows from all existing top-level relative placement groups at row position 1

```
prompt> modify_rp_groups  [get_rp_groups -top] -remove_rows {1 2}

1
```

See Also

- create_rp_group
- get_rp_groups
- write_rp_groups

---

move_block

Moves a block to a new block. The block can be moved to a different library or view.

Syntax

```
block_return move_block
[-force]
[-from_block blocks]
[-lib lib]
-to_block   block_name
```

Data Types

```
block_return     Collection containing block or "".
block            Block name in [libName:]blockName[/labelName][.viewName]
 format or
         a collection of one block.
block_name      Name in form [libName:]designName[/labelName][.viewName]
```

Arguments

`-force`

Moves the block to the destination, even if it is opened and unsaved.

Feedback

`-from_block` *blocks*

Specifies the source block name with optional library, label, and view specifications or a collection of blocks. If the library specification is not present, the *current_lib* is used. If the label specification is not present, then the default unnamed label is used. If the view specification is not present, the *design* view is used. By default, the *current_block* is used if this option is not specified.

`-to_block` *block_name*

Specifies the destination block name with optional library and view specifications. If the library, block, or view specifications are not present, the values from the source block are used.

`-lib` *lib*

Specifies the library to which the collection of blocks to be moved to. This option is exclusive to option *-to_block*.

Description

This command moves a source block(s) to the specified destination with the same or different library and block. Note that it is an error to attempt to move a block over itself. The command fails if the following conditions exist:

- The source library is opened in read-only mode
- The destination library is not open or is opened in read-only mode
- The destination block is open and has been modified but not saved and the *-force* option is not used
- An illegal name is given for the source or destination library, block, or view.
- The source block is a library cell block timing view. These views must be built "in place" in the library Manager because of library-level data.
- The destination block view is different than the source block view.

If successful, the destination block(s) can be further modified without any change in open mode. Note that the operation of this command is identical to the *copy_block*, except that the source block is removed (from memory, from the library, and from disk) after the block is successfully moved into its new location.

The command returns the block(s) if successful, or O if not. If an illegal name is given for the source or destination block names, a Tcl error is raised.

When no view is explicitly specified for both source and destination then all available views of source block are moved to destination block and all the moved blocks are returned.

Feedback

Examples

This example moves a block *Top* to *Top2* to rename it. The destination library and view are taken from the original block.

```
prompt> move_block -from_block Top -to_block Top2
{"Lib:Top2.design"}
```

This example moves a block Mid into a new library RefLib1.

```
prompt> move_block -from_block Mid -to_block RefLib1:
{"RefLib1:Mid.design"}
```

- remove_blocks
- reopen_block
- save_block

---

move_block_origin

Moves a block's origin to a new point in its own coordinate space.

Syntax

```
status move_block_origin
block
[-to point]
```

Data Types

```
block          string
point          list
```

Feedback

Arguments

block

Specifies the block to move the origin of. If unspecified, the current block's origin is moved. The syntax to specify *block* is [libName:]blockName[/labelName] [.viewName] format or a collection of one block.

-to *point*

Specifies the point in its own coordinate space to become its new origin. The syntax to specify *point* is {x y}, where x and y are new points in object's coordinates space.

Description

This command moves a block's origin to a new location in its own coordinate space. The new origin becomes (0, 0), and block's contents are shifted accordingly.

Examples

The following example moves the current block's origin to (100, 100), and illustrates the change in coordinates of one of block's member cells:

```
prompt> get_attribute [get_cells bot_0] origin
0.1250 -12.6000

prompt> get_attribute [get_cells bot_0] bbox
{0.1050 -12.6200} {12.6250 -0.1000}

prompt> move_block_origin -to {100 100}

prompt> get_attribute [get_cells bot_0] origin
-99.8750 -112.6000

prompt> get_attribute [get_cells bot_0] bbox
{-99.8950 -112.6200} {-87.3750 -100.1000}
```

See Also

- set_attribute
- get_attribute
- get_blocks
- current_block
- move_objects

Feedback

move_lib

Moves a library and its contents from one place to another.

Syntax

```
lib_return move_lib
[-force]
[-from_lib library]
 -to_lib   lib_name
```

Data Types

```
lib_return     Collection containing target library or "".
library        Name or collection containing the source library.
lib_name       name of the library.
```

Arguments

`-force`

This option is used to overwrite the destination library when the library is open, modified, but not yet saved.

`-from_lib lib_name`

Source library. If not given, the current_lib is used. This can either be a (full-path, relative-path, or simple) name, or a collection of a single library.

`-to_lib lib_name`

Specifies the destination library name.. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after he last '/' becomes the name of the library. It will be an error if the a library, file, or directory of the same name already exists on disk.

Returns

Returns the library if successful, or 0 if not. If an illegal name is given, a TCL error is raised.

Description

This command moves a library from one place to another in the file system. It is largely unnecessary as the LINUX mv(1) command will work also, but it is in our system form completeness. For both *copy_lib* and *move_lib*, care is taken to not read into memory any of the designs that are already in memory, so copying a large library is as efficient as it can be.

Examples

This example moves RefLib1, calling it RefLibA.

Feedback

```
prompt> move_lib -from_lib RefLib1 -to_lib RefLibA
{"RefLibA"}
```

See Also

- create_lib
- open_lib
- save_lib
- close_lib
- copy_lib
- current_lib
- get_libs
- set_ref_libs

---

move_objects

Moves and rotates the specified objects.

Syntax

status *move_objects*

```
[-delta delta]
[-from point]
[-to point]
[-x x]
[-y y]
[-rotate_by angle]
[-group]
[-force]
[-simple]
[object_list]
```

Data Types

```
delta        list of two floats: x and y
point        list of two floats: x and y
x            float
y            float
angle        float
object_list  collection or selection
```

Feedback

Arguments

object_list

Specifies a collection or selection set containing objects to move. If this option is not specified, the global selection set is used.

-delta *point*

Specifies the distance in the x- and y-directions to move the objects from the object's current location. This option is mutually exclusive with the *-to*, *-from*, *-x* and *-y* options.

-from *point*

Specifies the reference point on the object, or the collection of objects to be moved, for the *-to* option. By default, the command uses the lower-left corner of the bounding box of the given object, or collection of objects, as the reference point. This option must be used together with the *-to* option.

-to *point*

Specifies the new location of the reference point for the object or objects. This option is mutually exclusive with the *-delta*, *-x* and *-y* options.

-x *float*

Specifies the x-coordinate for the given object or collection of objects. All objects are moved so that their left edge is placed at the specified x-coordinate. This option is mutually exclusive with the *-delta*, *-from* and *-to* options.

-y *float*

Specifies the y-coordinate for the given object or collection of objects. All objects are moved so that their bottom edge is placed at specified y-coordinate. This option is mutually exclusive with the *-delta*, *-from* and *-to* options.

-rotate_by *angle*

Specifies the rotation angle of the objects.

The valid values are:

```
0, 90, 180, 270,
CW90, CW180, CW270, CCW90, CCW180, CCW270
FLIPX, FLIPY
R0, R90, R180, R270, MX, MXR90, MY, MYR90
```

The rotation value definitions are:

```
CW90     is 90 degrees clockwise
CW180    and CCW180 are 180 degrees
CW270    is 270 degrees clockwise
CCW90    is 90 degrees counterclockwise
```

Feedback

```
CCW270  is 270 degrees counterclockwise
FLIPX   is the reflection about the x-axis
FLIPY   is the reflection about the y-axis
```

The following values are synonymous:

```
0,   R0
90,  CCW90,  R90
180, CCW180, R180
270, CCW270, R270,
FLIPX, MY
FLIPY, MX
```

`-group`

Specifies if rotation should be made around common pivot point. If omitted, the rotation is performed around the object centers.

`-force`

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using *get_edit_setting*.

`-simple`

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using *get_snap_setting*.

Description

This command moves one or more specified objects to a given location skipping all fixed or locked objects. The command keeps pin/terminal on edge of parent block and updates its layer if corresponding edit setting is set. See the *set_edit_setting* command for details.

Snapping is done automatically using the global snap settings.

Examples

The following example moves all selected objects by delta (-100 100).

```
prompt> move_objects -to {-100 100} -from {0 0}
```

The alternative syntax uses collection to specify objects.

```
prompt> move_objects [get_selection] -to {-100 100} -from {0 0}
```

- set_edit_setting
- set_snap_setting
- snap_objects

n

name_format

Specifies the name format for the isolation cells and level shifters.

Syntax

status *name_format*

```
[-isolation_prefix name]
[-isolation_suffix name]
[-level_shift_prefix name]
[-level_shift_suffix name]
```

Data Types

```
name          string
```

Arguments

`-isolation_prefix`

Specifies the prefix to use for the isolation cell names. The default is "".

`-isolation_suffix`

Specifies the suffix to use for the isolation cell names. The default is "_UPF_ISO".

`-level_shift_prefix`

Specifies the prefix to use for the level-shifter cell names. The default is "".

`-level_shift_suffix`

Specifies the suffix to use for the level-shifter cell names. The default is "_UPF_LS".

Feedback

Description

This command specifies the suffix and prefix for the isolation and level-shifter cells. The name of the element that is being isolated or level shifted by the isolation or the level-shifter cell is used in the middle. For example, an isolation cell that isolates a port named *p1* is named *p1_UPF_ISO* by default.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following is an example of the *name_format* command:

```
prompt> name_format -isolation_prefix "MY_ISO" -level_shift_prefix
 "MY_LS"
```

See Also

- set_isolation
- set_level_shifter

O

---

open_attachment

Opens a file handle for the given attachment.

Syntax

status *open_attachment*

```
names
-mode file_mode
[-of_object object]
```

Data Types

```
names      list
file_mode  string
object     collection
```

Arguments

names

List of attachment names to be reported. Supports glob style patterns.

Feedback

`-mode` *`file_mode`*

Specifies the mode for opening the file. All the modes that work with Tcl "open" command are supported.

`-of_object` *`object`*

Specifies the object whose attachments will be opened. By default the current block and current library will be considered in that order as the owner object.

Description

This command opens a file handle for the attachment with the given name and for the specified owner object. The file handle is open in the mode specified. The command should be used in a similar fashion as the Tcl "open" command to open the file handle.

Examples

In the following example the file handle is opened and used for the given attachment.

```
prompt> set fh [open_attachment -of_object [current_block] -mode r
 test_att]
 file23
prompt> read $fh
 ATTACHMENT CONTENTS
```

See Also

- add_attachment
- remove_attachments
- report_attachments

---

open_block

Opens an existing saved block for editing or viewing and sets that block as the current block.

Syntax

```
collection open_block
[-edit | -read | -check]
[-not_as_current]
[-ref_libs_for_edit]
[block_name]
```

Data Types

```
block_name    string
```

Feedback

Arguments

`-edit`

Opens the block in edit (read/write) mode, allowing you to modify and save the block. This is the default mode for opening a block in a design library. To open a block in edit mode, you must have write permission for the directory containing the block and library, and the block must not be already locked for editing by another user.

`-read`

Opens the block in read-only mode, allowing you to view but not modify or save the block.

`-check`

Checks for existence of the block in memory. Returns the block if it is already in memory, or returns an error message otherwise. Mutually exclusive with *-read* and *-edit*.

`-ref_libs_for_edit`

Opens lower-level design libraries (those appearing in the reference library list) in edit mode so that lower-level blocks can be modified. Reference libraries containing lib_cell blocks remain in read-only mode, even when this option is used. This option can only be used when opening a block in edit mode, either by using the default open mode or explicitly with *-edit* option.

`-not_as_current`

An optional argument to open a block without setting it as a current block.

`block`

A collection of one block or name of the block to open, with optional *library*, *label*, and *view* names specified. The default names are the current library, no label, and the design view.

Description

This command opens an existing saved block for editing or viewing and sets that block as the current block. The block is opened in edit mode by default or when the *-edit* option is used. The block is opened in read-only mode when the *-read* option is used. With the *-check* option, the command returns the block as a collection if it is already in memory, or an error message otherwise.

By default, when you open a block in edit mode, when the block is in an open read-only library, the command promotes the library to edit mode so that you can edit the block in the library. To prevent this action and protect the library from being accidentally modified, set the *design.edit_read_only_libs* application option to false.

Feedback

An implementation tool can open library cell blocks in cell libraries only in read-only mode. To edit library cell blocks, use the library manager tool (lm_shell).

The *open_block* command increments the "open count" for a block (unless you are using the *-check* option). The open count can affect the read/write status of the block. For example, if you open a block using *-edit* and the again using *-read*, the read/write status of the block remains in "edit" mode due to the status of the earlier open operation (earlier open count).

Furthermore user may choose to open a block without setting the block as current block by using *-not_as_current* option.

Examples

The following example opens the existing block "Top" from the library "MyDesigns":

```
prompt> open_block -edit MyDesigns:Top
{"MyDesigns:Top.design"}
```

The following example opens the timing view of lib_cell AN2 from the library MyLibCells:

```
prompt> open_block -read MyLibCells:AN2.timing
{"MyLibCells:AN2.timing"}
```

The following example opens the existing block "Top" from the library "MyDesigns" but not set the block as current block.

```
prompt> open_block -edit MyDesigns:Top -not_as_current
{"MyDesigns:Top.design"}
```

---

open_drc_error_data

Opens an error data file so that you can query or modify the error data.

Syntax

```
collection open_drc_error_data
[drc_error_data]
[-file_name file_name]
[-readwrite]
[-readonly]
[-checkonly]
```

Data Types

```
drc_error_data   collection
file_name        string
```

Arguments

drc_error_data

Specifies the attached error data file to open. You can use the file name, such as zroute.err, or a collection that contains the error data file.

To determine the error data files attached to the current block, use the *get_drc_error_data -all* command. You must use the *-all* option to return both the open and unopened error data files.

This argument is mutually exclusive with the *-file_name* option; you must specify one of these arguments.

`-file_name` *file_name*

Specifies the file path of an external error data file to open.

This argument is mutually exclusive with the *drc_error_data* argument; you must specify one of these arguments.

`-readwrite`

Opens the specified external error data file in read/write mode.

When you enable this mode, the tool can modify the contents of the error data file. If you open a file in read/write mode, it stays in that mode even if you later open it in read-only mode.

Feedback

This is the default open mode for external error data files, which are opened with the *-file_name* option.

The tool ignores this option when opening attached error data files and uses the open mode of the block.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

`-readonly`

Opens the specified external error data file in read-only mode. However, if you previously opened the file in read/write mode, the file remains in read/write mode.

When you enable this mode, the tool cannot modify the contents of the error data file.

The tool ignores this option when opening attached error data files and uses the open mode of the block.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

`-checkonly`

Checks if the specified error data file is already open and returns a collection that contains the error data object if the file is open. If the file is not open, it returns an empty string.

The *-readwrite*, *-readonly*, and *-checkonly* options are mutually exclusive; you can specify only one.

Description

The *open_drc_error_data* command opens an error data file so that you can query or modify the error data. The command supports both attached error data files and external error data files.

- Attached error data files are stored in the design library.

  To open an attached error data file, specify its name or a collection that contains the error data file as a command argument.

  When you open an attached error data file, the tool always opens the file using the current block's open mode.

- External error data files are stored on disk.

  To open an external error data file, specify its file path with the *-file_name* option.

Feedback

When you open an external error data file, by default, the tool opens the file in read/write mode. To explicitly specify the open mode, use the *-readwrite* or *-readonly* option. When you use these options, the *-readwrite* option has the highest precedence. If you open the error data the *-readwrite* option and then open it again with the *-readonly* option, the open mode remains read/write.If you first open the error data with the *-readonly* option, and then open it again with the *-readwrite* option, the open mode changes to read/write.

The *open_drc_error_data* command increments the open count for the error data, except when you use the *-checkonly* option. The *open_drc_error_data* commands must be balanced by an equal number of *close_drc_error_data* commands to close the error data object.

The command returns a collection that contains the opened error data file. If no file is opened, the command returns an empty string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example opens the dppinassgn.err error data file attached to the current block and returns a collection that contains the error data file.

```
prompt> open_drc_error_data dppinassgn.err
{dppinassgn.err}
```

The following example opens the external error data file named "./my_design_dppinassgn.err" in read/write mode and returns a collection that contains the error data file.

```
prompt> open_drc_error_data -file_name ./my_design_dppinassgn.err
{my_design_dppinassgn.err}
```

---

open_ems_database

Opens an existing EMS database.

Syntax

```
collection open_ems_database
ems_database_name
```

Data Types

ems_database_name string

Arguments

ems_database_name

Specifies the name of the EMS database. If the specified EMS database does not exist, the command issues an error message.

Description

The *open_ems_database* command opens an existing EMS database and makes it the current, active database.

Examples

The following example returns the currently open EMS database, opens the EMS database named abc.ems, then shows that abc.ems is now the current EMS database.

```
prompt> get_current_ems_database
{def.ems}
prompt> open_ems_database abc.ems
{abc.ems}
prompt> get_current_ems_database
{abc.ems}
```

---

open_fusion_thermal_result

Load thermal database into memory.

Syntax

status *open_fusion_thermal_result*

`[-result result]`

Data Types

result string

Arguments

`-result result`

Specifies the result name.

Description

Load thermal database into memory.

Examples

The following example shows the usage:

```
prompt> open_fusion_thermal_result -result RESULT
```

See Also

- analyze_thermal
- close_fusion_thermal_result

- thermal.heat_transfer_rate
- thermal.hier_block_metal_profile
- thermal.hier_block_power_profile
- thermal.metal_density

Feedback

- thermal.metal_profile
- thermal.percentage_of_max_threshold
- thermal.power_layer
- thermal.power_profile
- thermal.tech_file
- thermal.threshold
- thermal.use_layout

---

open_lib

Open an already-existing library for edit or read access.

Syntax

```
open_return open_lib
[-edit | -read]
[-ref_libs_for_edit]
[-recover]
library_name
```

Data Types

```
open_return    Collection containing the library or "".
library_name   Library name in simple, relative, or absolute path.
```

Arguments

`-edit`

Opens the library in edit mode.

This is the default for design libraries if you do not specify any options with this command.

In an implementation tool, cell libraries can be opened only in read mode. If you try to explicitly open a cell library in edit mode, the command issues a warning message and the library is opened in read mode.

This option is mutually exclusive with the *-read* option and is not available in the library manager.

`-read`

Opens the library is read-only mode.

This is the default open mode for cell libraries in an implementation tool.

Feedback

This option is mutually exclusive with the *-edit* option and is not available in the library manager.

`-ref_libs_for_edit`

Open reference module libraries in edit mode so that lower-level designs can be modified. Lib-cell libraries will still be open in read mode even if this option is used. This option can only be used when opening a design library in edit mode, ether by using the default open mode or explicitly with -edit.

To edit cell libraries, use the edit flow in the library manager (lm_shell).

This option is not available in the library manager.

`-recover`

Recovers the latest auto-saved library of the given library. Auto-saved library will recovered and opened as a new library and won't be merged into the current or original library.

`library_name`

Specifies library to open.

Because library names become directory or file names, they cannot contain the slash ("/") or colon (":") character.

Returns

Returns the library if successful, or 0 if not. If an illegal name is given, a Tcl error is raised.

Description

This command opens a pre-existing library. The library can be in is distributed (file-system hierarchical) form or a single-file form. The library name can be given as a full path name, a relative path name, or a single name. In the last two cases, the search_path is used to determine the full path for the library. When the library is opened, its design catalog is read in, but no designs are read in until they are opened explicitly (through open_block) or implicitly (by being bound to from another design). As a library is being opened through this command, all of the libraries on its ref-lib list are also opened in read-only mode. These reference libraries have their design catalogs read in, but their reference libs are not read in until and unless the reference lib is also explicitly opened. The technology section in the design library, or the technology section of the dedicated technology library in the reference libraries, or the first technology section found in its reference libraries if no technology library is specified, becomes the technology data for the design library. In the library manager,if an aggregate flow is created, this command adds the cell library to an aggregate library. To edit the cell library, use the edit flow in the library manager (lm_shell).

Examples

The following command opens the design library MyDesigns.

Feedback

```
prompt> open_lib MyDesigns
INFO: loading technology data from "MyLibCells"
1
prompt> get_libs
{"MyDesigns"}

prompt> get_libs -all
{"MyDesigns" "RefLib1" "RefLib2" "MyLibCells"}
```

---

open_ml_db

Opens an existing database.

Syntax

string *open_ml_db*

```
-datastore cassandra | serverless
[-server server_path]
database_name
```

Data Types

```
server_path      string
database_name      string
```

Arguments

`-datastore cassandra | serverless`

Specify the datastore.

Feedback

`-server` *server_path*

An optional argument that defines server location for "cassandra" datastore. By default it will use the path from the CERBERUS_HOME environment variable. No effect to "serverless" datastore.

database_name

The name of the database to open. For "serverless" datastore, the "/" in the name indicates the delimiter of directory path.

Description

This command opens a database and connects to it.

This command returns the name of the opened database if successful, or "0" if not, with a TCL error raised.

Examples

The following example opens a database "demo_ml_db" in the cassandra datastore.

```
prompt> open_ml_db -datastore cassandra demo_ml_db

The following example opens a database "ml_db" of serverless datastore in
 the
directory "./demo".

prompt> open_ml_db -datastore serverless ./demo/ml_db
```

See Also

- create_ml_db
- close_ml_db
- remove_ml_db

---

open_rail_result

Opens the rail result data that is generated by the RedHawk Analysis Fusion rail analysis run.

SYNTAX

(ICC2 2D design)

status *open_rail_result*

```
[result_name]
[-voltage_drop static | dynamic | dynamic_vectorless
 | dynamic_vcd | sigma_dvd | sigma_pd | sigma_av]
```

Feedback

```
[-block_instance block_instance_name]
[-top_design top_design_name]
[-back_annotate]
[-num_row num_row]
[-num_col num_col]
```

(3DIC Compiler 2D design)

status *open_rail_result*

```
[result_name]
[-num_row num_row]
[-num_col num_col]
```

(3DIC Compiler 3D design)

status *open_rail_result*

```
                [-inst_name inst_name]
[-num_row num_row]
[-num_col num_col]
```

Data Types

```
result_name              string
block_instance_name      string
top_design_name          string
inst_name                string
num_row                  integer
num_col                  integer
```

Arguments

result_name

Specifies the name of the rail result to open. The default name is "REDHAWK_RESULT".

-voltage_drop *static* | *dynamic* | *dynamic_vectorless* | *dynamic_vcd* | *sigma_dvd* | *sigma_pd* | *sigma_av*

Specifies analysis mode to load a SigmaDvD flow or Eff-VD flow result.

-block_instance *block_instance_name*

Specifies the full path of the block instance whose rail result data is to be shown. When specified, the *open_rail_result* command loads the rail result of the top design, crops the result by the given block instance, and then opens the cropped result. Note that the opened current design is a block design, not top design. This option must be used with the *-top_design* option to specify the name of the top design.

Feedback

`-top_design` *top_design_name*

Specifies the name of the top design and crops the top design's rail result by the *-block_instance* option. The option must be used with *-block_instance* option.

`-back_annotate`

Forces to reconvert RAIL_DATABASE from the RedHawk/RedHawk-SC result. This attempts to recover a previous result after a design change. Instance based results refreshs the geometry. while para-based results do not refresh geometry. Newly created design elements do not have any result.

`-inst_name`

Opens block result from 3d result generated by analyze_3d_rail from 3dic_shell. Must first open block design instead of virtual top before invoking *open_rail_result* using this switch. Application option *rail.database* should still point to 3d result top rail database path. This option can only be used in 3dic_shell.

`-num_row`

Number of rows to load a 2d grid in a 3d result. This option can only be used in the 3dic_shell.

NOTE: Default is 1024

`-num_col`

Specifies the number of columns to load a 2d grid in a 3d result. This option can only be used in the 3dic_shell.

NOTE: Default is 1024

Description

The *open_rail_result* command opens the rail result data that is generated by the *analyze_rail* command. With the rail result data loaded, you can then check the RedHawk Analysis Fusion analysis results by displaying the maps or querying attributes.

The rail results are saved in the RAIL_DATABASE directory inside the RedHawk work directory. To list the available rail results, use the *report_rail_result* command.

current rail result.

You can use the *set_app_options -name rail.database -value _rail_database_path_* command to switch to a different RAIL_DATABASE, but not while a rail result is already open.

If you want to debug voltage drop issues in the block design with only rail analysis result data for the top design, use the *-block_instance* and *-top_design* options to crop the top

Feedback

design's rail result for the specified block instance. You can then display maps or query attributes based on the cropped result for the specified block instance.

Examples

The following example opens the rail result data with default result name.

```
prompt> open_rail_result
1
```

Assume the current design name is CORE and it's instantiated in the top design by instance name u_core_1, the following example opens the top design's rail result on u_core_1 only.

```
prompt> open_rail_result -top_design top -block_instance u_core_1
1
```

The following example force reconverts RAIL_DATABASE from RedHawk/RedHawk-SC result.

```
prompt> open_rail_result ... -back_annotate
1
```

The following example opens block result from 3dic_shell.

```
prompt> open_block logic_die
prompt> set_app_options -name rail.database -value ...
prompt> open_rail_result -inst_name logic_die_inst
1
```

See Also

- analyze_rail
- report_rail_result
- close_rail_result
- set_app_options

---

optimize_ai

Runs the Fusion native AI flow

Syntax

```
status optimize_ai
-slice_name place | compile | clock | route
-scripts user_script
[-baseline_only]
[-dont_launch]
```

Feedback

```
[-dso_shell_pre_script shell_script]
[-dso_shell_post_script shell_script]
[-intent power | timing | leakage]
[-number_of_waves num_waves]
[-number_of_run_slots num_run_slots]
[-relaunch_from relaunch_from]
[-replay_from_slice replay_slice]
[-run_wave wave_num]
[-post_script custom_script]
[-pre_script custom_script]
[-previous_slice previous_slice]
[-force_overwrite]
```

Data Types

user_script	list
shell_script	list
num_waves	integer
num_run_slots	integer
relaunch_from	string
replay_slice	string
wave_num	integer
custom_script	list
previous_slice	string

Arguments

`-slice_name` *slice_name*

Specifies the slice name to run. The slice name can be one of the following: place, compile, clock, or route. For fusion compiler the compile slice name should be used, and place should be used for ICC2.

`-scripts` *user_script*

Specifies the scripts to run. The user_script is a list of one or more scripts to run. If multiple scripts are provided then each script is run sequentially in the order provided, and each script is launched in a separate process.

So, *-scripts {build_clock.tcl clock_opt.tcl}* results in a process being launched that runs the build_clock.tcl script. When that script finishes, a new process is launched to run the script clock_opt.tcl. Therefore it is important that the scripts are written accordingly. For example the build_clock.tcl script could save an NDM block called build_clock, which would then be opened by the clock_opt.tcl script.

`-baseline_only`

Specifies that the baseline flow only should be run. This option is used to run the baseline flow only, without launching any exploration runs. This is useful when flushing through scripts, to make sure there are no errors before launching multiple runs. This will launch 1 run only.

`-dont_launch`

Can be used to just generate the run directories and scripts, without actually launching any jobs.

`-dso_shell_pre_script` *`shell_script`*

Specifies a list of shell scripts to run before the DSO shell is launched. These scripts must end with .sh or .csh, and all scripts require the same extension, so if you use .csh, then all specified scripts need to be .csh scripts. One dso_shell_pre_script is supported per user_script. If you specify multiple user_scripts, for example, *-scripts {build_clock.tcl clock_opt.tcl}*, then you can specify a list of dso_shell_pre_script's *-dso_shell_pre_script {pre_script1.sh pre_script2.sh}*. In this example the *pre_script1.sh* runs before the *build_clock.tcl* script, and the *pre_script2.sh* runs before the *clock_opt.tcl* script. If you are only specifying a single user_script, then you can only specify one dso_shell_pre_script.

`-dso_shell_post_script` *`shell_script`*

Specifies a list of shell scripts to run after the DSO shell has finished. These scripts must end with .sh or .csh, and all scripts require the same extension, so if you use .csh, then all specified scripts need to be .csh scripts. One dso_shell_post_script is supported per user_script. If you specify multiple user_scripts, for example, *-scripts {build_clock.tcl clock_opt.tcl}*, then you can specify a list of dso_shell_post_script's *-dso_shell_post_script {post_script1.sh post_script2.sh}*. In this example the *post_script1.sh* runs after the *build_clock.tcl* script, and the *post_script2.sh* runs after the *clock_opt.tcl* script. If you are only specifying a single user_script, then you can only specify one dso_shell_post_script.

`-intent power | timing | leakage`

Specifies the intent of the run. The intent can be one of the following: *power*, *timing*, or *leakage*. The default is *power*. The intent is used to determine the optimization strategy for the run scripts. For example:

o *-intent power* : optimizes for total power, and run selection is weighted for power improvement. Timing is always a priority so specifying *-intent power* does not ignore timing, however trade offs can be made.

o *-intent timing* : optimizes for timing, and run the selection is weighted for timing improvement.

o *-intent leakage* : optimizes for leakage, and run selection is weighted for leakage improvement. Timing is always a priority so specifying *-intent leakage* does not ignore timing, however trade offs can be made.

Feedback

set_qor_strategy settings should be set in the user_scripts, the intent specified here does not override the settings in the user_scripts, it augments them to improve QOR, focusing on the intent specified.

`-number_of_waves` *`num_waves`*

Specifies the number of waves to run. The number of waves determines how many iterations of the flow are run. The default is 1. The maximum number is 2. Increasing the number of waves increases the flow runtime, with the objective of improving QOR.

`-number_of_run_slots` *`num_run_slots`*

Specifies the number of run slots to use (the number of jobs to run in parallel). The default is 5, or 6 if true_baseline is specified (*set_optimize_ai_options -true_baseline true*). If you want to use fewer run slots (you cannot use more), then the number you specify here is honored explicitly. So if you specify 4, then a maximum of 4 jobs are run in parallel, irrespective of whether *-true_baseline* is true or false.

`-relaunch_from` *`relaunch_from`*

If a script error occurs such that the runs errors out, then you would typically fix the script issue and rerun. However, if you have specified multiple user_scripts, for example, *-scripts {build_clock.tcl route_clock.tcl clock_opt.tcl}* and the script error occurs in *route_clock.tcl* then you might want to rerun from the failed script to save having to rerun any prior scripts that completed without any errors. *-relaunch_from route_clock.tcl* relaunches the run from the script *route_clock.tcl*.

The option only works if the run failed, you cannot use this option to relaunch a successfully completed run.

`-replay_from_slice` *`replay_slice`*

If you have completed a previous run, then you can replay the flow, even if the incoming RTL / design data has changed. To use this feature you first need to specify the location of the previous run via *set_optimize_ai_options -reference_work_dir work_dir*. After this has been provided you than specify the slice from which you want to extract replay information. For example maybe you want to replay the best compile slice, you can simply do

```
prompt> set_optimize_ai_options
 -reference_work_dir /run1/work_fcdso
prompt> optimize_ai -slice compile -scripts compile.tcl
 -replay_from_slice compile
```

This extracts the data required to replay the best run from the compile slice (located in the reference_work_dir) and launches a single replay run (by default this runs in the work_fcdso directory). However, you might want to replay the

Feedback

compile slice that resulted in the best route slice result, remember it's possible the run selection was overridden. In this case you can simply do:

```
prompt> set_optimize_ai_options
 -reference_work_dir /run1/work_fcdso
prompt> optimize_ai -slice compile -scripts compile.tcl
 -replay_from_slice route
```

This looks at the best route slice result, and traces back to the run_id from the compile slice that was used to generate the best route slice result. It is this compile slice from which the replay information is extracted.

If you want to extract replay information from a specific run_id, for example, if you want to extract replay information from run_id a429625 for the route slice then you can do:

```
prompt> set_optimize_ai_options
 -reference_work_dir /run1/work_fcdso
prompt> optimize_ai -slice compile -scripts compile.tcl \\
                       -replay_from_slice {slice:route
 runid:a429625}
```

`-run_wave` *`wave_num`*

If you are running 2 iterations of the flow, for example, *-number_of_waves 2*, then *optimize_ai* first launches wave one (*slice_name*_1), and when this completes the runs are analyzed and the second wave of runs are orchestrated and launched (*slice_name*_2).

However, sometimes you might want to run the waves separately. You can do that by using the *-run_wave* option, for example:

```
prompt> optimize_ai -slice compile -scripts compile.tcl
 -number_of_waves 2 -run_wave 1
```

The previous example tells *optimize_ai* that the you intend to run 2 waves, but want to run the waves separately. Wave 1 is run and when it completes you can then run wave 2 by running

```
prompt> optimize_ai -slice compile -scripts compile.tcl
 -number_of_waves 2 -run_wave 2
```

This can be run either in the same FC session or in a separate session, however, if you do run in a separate session make sure to specify the *set_optimize_ai_options* again.

`-post_script` *`custom_script`*

Specifies a list of custom Tcl scripts to run after the user_script has completed, this can be used, for example, to easily add additional reporting to a flow.

Feedback

`-pre_script` *`custom_script`*

Specifies a list of custom scripts to run before the user_script is executed.

`-previous_slice` *`previous_slice`*

Specified the name of the previous slice. This is used to determine where to look for the best run from the previous slice to use as the source of the current slice. This is optional, for example when you might not have a previous slice, if you are running the compile or place slices.

When you specify *-previous_slice*, the best run (and true_baseline run, if enabled) are brought forward into the current slice. To be specific, the directory specified via the *-design_data_dir* option of *set_optimize_ai_options*, is copied from the best run directory of the previous_slice. This selection is done automatically. However, if you want to override the selection for any reason you can specify a previous slice, and runid, by specifying a list of the form {slice:*slice_name* runid:*run_id*}, for example, to select the run df021d2 from the previous compile slice, you would specify

```
prompt> optimize_ai -slice clock -scripts clock.tcl \\
                    -previous_slice {slice:compile runid:df021d2}
```

Sometimes you want to run experiments, maybe you have a new script that you want to try for your clock runs, however your previous_slice data is located in a different directory. In such cases you ca use the workdir: keyword to specify the directory where the previous slice data is located. For example if the data for your compile run is located in /run1/work_fcdso and you are running in directory /run2, you can specify

```
prompt> optimize_ai -slice clock -scripts clock.tcl \\
                      -previous_slice {workdir:/run1/work_fcdso
 slice:compile}
```

`-force_overwrite`

If an existing slice directory is found, for example, maybe you are rerunning after correcting a script or design data issue, then you either need to manually remove the directory or use the -force_overwrite option to automate the removal.

Description

Runs the Fusion AI optimization flow on the user_scripts. Prior to running this command you must specify some mandatory settings using the *set_optimize_ai_options* command, the mandatory settings are *-design_data_dir*, *-grid_settings* and *-resource_names*.

optimize_ai launches runs in the directory specified via the *set_optimize_ai_options -work_dir directory*. The default name is work_fcdso. So if you were to run

```
prompt> optimize_ai -slice compile -script {scripts/compile.tcl}
```

Then a directory called work_fcdso is created, and inside this directory another directory called compile_1 is created for example *slice_name_wave_num*. The compile_1 directory is where DSO is launched. Once the runs for a slice complete, a directory called best_run is created and a symbolic link is created to the best run for that slice. This is done so that the best run cab be easily accessed.

The following is an example of the textual report generated by *optimize_ai* after a slice has completed. The first column provides a numerical ID for each of the runs, with 'B' being the true_baseline. The RUN_ID is the run ID of the run, and the SCORE is the relative grading of the results.

```
AIFS-Info: Collected 6 new runs in work_fcdso/clock_1

      RUN_ID     SLICE     SCORE        WCV      FCTNS  HOLD_FCTNS
 WTOT_STD_PWR  WLKG_STD_PWR  STDCELL_AREA  CONGESTION   RUNTIME
2    9ae2ed1   clock_1    0.9321      1.024    -0.3138     -0.5799
 0.1733       0.01131         17.46           0    0.0661
4    e1ce6a0   clock_1    0.9357          1      -0.31     -0.5729
 0.1745       0.01163         21.22           0    0.0614
1    b7a96e4   clock_1    0.9449          1     -0.316     -0.5589
 0.1761       0.01239         21.54           0    0.0744
3    26de243   clock_1    0.9936      1.031    -0.3122      -0.575
 0.1815       0.01411         20.24           0    0.0522
B    efdca75   clock_1     1.008      1.015     -0.309     -0.5804
 0.1835       0.01451         18.93           0    0.0744
5    1964132   clock_1     1.009      1.016    -0.3091     -0.5795
 0.1835       0.01451         18.93           0    0.0689

RUN_ID        - The unique run_id for the run.
  SLICE         - The slice for which the run has been run, followed by
 the wave number.
  SCORE         - The Fusion AI score for the run. The lower the score
 the better the run.
  WCV           - The Worst Clock Violation  = (period - slack)/period
 similar to WNS but relative to target clock period
  FCTNS         - TNS = Total Negative Slack for the run
  R2R_FCTNS     - R2R TNS = Register to Register TNS for the run
  HOLD_FCTNS    - Total Negative Hold Slack for the run
  WTOT_PWR      - Total Power for the run
  WTOT_STD_PWR  - Total Standard Cell Power for the run
  WLKG_PWR      - Total Leakage Power for the run
  WLKG_STD_PWR  - Total Standard Cell Leakage Power for the run
  STDCELL_AREA  - Total Standard Cell Area for the run
  CONGESTION    - Congestion for the run (lower is better)
  RUNTIME       - Runtime for the run
```

The SCORE is used by Fusion AI to grade the runs. This is a combination of insight run analysis and metric analysis. The lower the score the better the run. The score is influenced by the specified -intnet, so if you specify -intent power, the score will be weighted towards power.

Feedback

Examples

Example1: The following example shows how to run the *optimize_ai* command for three slices, with the true_baseline being enabled.

```
set_optimize_ai_options \
    -grid_settings { set_lsf_options -name grid_launch -app_profile batch
 -resource_requirement {'rusage[mem=12GB] span[hosts=1]'} -thread_count
 4 } \\
    -resource_names {grid_launch} \\
    -design_data_dir ./data \\
    -true_baseline true

optimize_ai -slice compile -script {scripts/compile/run.tcl}

optimize_ai -slice clock -script {scripts/clock/run.tcl
 scripts/clock_opt/run.tcl} \\
    -previous_slice compile

optimize_ai -slice route -script {scripts/route/run.tcl
 scripts/route_opt/run.tcl} \\
    -previous_slice clock
```

Example2: Run 5x2 for compile slice, and 5x1 for all other slices

```
set_optimize_ai_options \\
    -grid_settings { set_lsf_options -name grid_launch -app_profile batch
 -resource_requirement {'rusage[mem=12GB] span[hosts=1]'} -thread_count
 4 } \\
    -resource_names {grid_launch} \\
    -design_data_dir ./data

optimize_ai -slice compile -script {scripts/compile/run.tcl}
 -number_of_waves 2

optimize_ai -slice clock -script {scripts/clock/run.tcl
 scripts/clock_opt/run.tcl} \\
    -previous_slice compile

optimize_ai -slice route -script {scripts/route/run.tcl
 scripts/route_opt/run.tcl} \\
    -previous_slice clock
```

Example3: Override the run selection from the compile slice when running the clock slice. In this example run df021d2 is chosen as the best run from the compile slice:

```
set_optimize_ai_options \\
    -grid_settings { set_lsf_options -name grid_launch -app_profile batch
 -resource_requirement {'rusage[mem=12GB] span[hosts=1]'} -thread_count
 4 } \\
    -resource_names {grid_launch} \\
    -design_data_dir ./data
```

Feedback

```
optimize_ai -slice compile -script {scripts/compile/run.tcl}
 -number_of_waves 2

optimize_ai -slice clock -script {scripts/clock/run.tcl
 scripts/clock_opt/run.tcl} \\
    -previous_slice {slice:compile runid:df021d2}
```

---

optimize_dft

Performs timing-aware placement based or clock-aware scan reordering.

Syntax

status *optimize_dft*

`[-clock_aware]`

Arguments

`-clock_aware`

Invokes clock-aware scan reordering, which aims to minimize the number of clock buffer crossings in the scan chain for better hold violation reduction along the scan path.

Description

The *optimize_dft* command performs scan chain reordering. By default, it performs timing friendly placement based reordering. It aims to reduce the scan chain wire length, minimize the setup timing violation along scan path, benefit congestion, and improve routability. Prior to using this command you must enable scandef into has been read into the design, and placement has been performed on the design.

When invoked with the *-clock_aware* option, the *optimize_dft* command performs clock-aware scan reordering. The reordering aims to minimize the number of clock driver crossings of the scan cells within the scan chain. Minimizing the number of clock driver crossings can reduce hold time violations in the scan chain. For best results, you should first perform timing friendly placement based scan reordering.

For best results, you should use the *place_opt* and *clock_opt* commands instead of the *optimize_dft* command. The *optimize_dft* command is provided for advanced users who want to have finer control over the placement and clock tree synthesis processes.

Feedback

The standalone *optimize_dft* command does not update extraction or timing data so you must do that.

Moreover, before performing any optimization, you should run the *check_scan_chain* command because only "VALIDATED" scan chains are optimized with the *optimize_dft* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

- place_opt
- clock_opt
- check_scan_chain

---

optimize_rdl_routes

Optimizes the RDL routing patterns.

Syntax

status *optimize_rdl_routes*

```
[-nets collection_of_nets | -nets_in_file nets_file]
[-objects collection_of_objects]
-layer tech_layer_name
[-reserve_power_resources true | false]
```

Data Types

```
collection_of_nets     collection
nets_file              string
collection_of_objects  collection
tech_layer_name        string
```

Arguments

`-nets collection_of_nets`

Specifies the nets to be optimized. By default, all RDL nets are optimized.

`-nets_in_file nets_file`

Specifies the name of a file that contains the list of nets to be optimized.

-nets has higher priority than *-nets_in_file*.

Feedback

`-objects` *`collection_of_objects`*

Specifies the RDL nets (see *-nets*) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option *flip_chip.route.routing_style* is *spanning_tree*, the whole nets of the cells or pins are regarded as involved.

`-layer` *`tech_layer_name`*

Specifies the metal layer on which to optimize the RDL wires. You specify the metal layer by using its technology file layer name.

This option is required.

Use the *create_routing_rule* command to specify the required width and spacing of the thin nets before using this function.

`-reserve_power_resources true | false`

Specifies whether to create additional routing channels for power routing. When this option is true, the command reserves power resources by pushing RDL routing wires to create extra routing channels between the bump cells. After running the command with this option, the amount of 'U' and 'Z' routing shapes might increase. By default, the option is false and the command does not create additional routing channels.

Description

This command improves and enhances the RDL routing patterns by removing and reducing the amount of 'U' and 'Z' routing shapes in the design. In order to get better optimization result, floating or dangling RDL routes will be removed to gain more space for optimizing completed routed RDL paths. To keep the floating or dangling RDL routes, please change 'shape_use' to 'user_route' before executing this command.

RDL nets are nets in flip-chip designs or 3DIC designs which are routed on the redistribution layer. In a flip-chip design, RDL nets connect a bump cell to driver I/O cells. In a 3DIC or interposer design, RDL nets can connect the following elements:

- A micro-bump cell and a micro-bump cell
- A micro-bump cell and a TSV (through silicon via) cell
- A micro-bump cell and driver I/O cell

Micro-bump cells are also called flip-chip pads.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example optimizes the RDL routing patterns on the METAL9 layer.

```
prompt> optimize_rdl_routes -layer METAL9
```

The following example optimizes the RDL routing patterns in NET1 and NET2 nets on the METAL7 layer.

```
prompt> optimize_rdl_routes -layer METAL7 -nets {NET1 NET2}
```

---

optimize_routability

Optimizes the routability of a design.

Syntax

status *optimize_routability*

```
[-drc_rules drc_rules_list]
[-layer_rules layer_list]
[-keepout_width width]
[-flip]
[-route]
[-remove_keepouts]
[-check_drc_rules]
[-one_side_keepout]
```

Data Types

```
drc_rules_list   list
layer_list       list
width            float
```

Arguments

`-drc_rules drc_rules_list`

Specifies the DRC rules to work on. This should be a list consisting of one or more lists of the name of the DRC rule and its corresponding layer. If this option or *-layer_rules* option is not specified, then all DRC rules are considered.

Feedback

`-layer_rules` *layer_list*

Specifies the layer names to work on. If this option or *-drc_rules* is not specified, then all DRC rules are considered.

`-keepout_width` *width*

Specifies the keepout width to use, in microns. The default value is the site width.

`-flip`

Specifies that orientation changes are performed instead of spacing cells apart.

`-route`

Performs *route_eco* command and *check_routes* command. The route option used is *modified_nets_first_then_others.*

`-remove_keepouts`

Removes all keepouts that are inserted by *optimize_routability* command. This can be performed at the end of optimize routability.

`-check_drc_rules`

Prints information about DRC rules. If this option is specified, other options are ignored. The design remains unchanged.

`-one_side_keepout`

Applies keepouts only on one side of the cell.

Description

The *optimize_routability* command helps to improve routability of a design by spacing cells further apart with the use of the keepout margins or by flipping cells. Run *check_routes* command before using this command to ensure that the DRC error information is up-to-date.

Examples

The following example runs the *optimize_routability* command using specified DRC rules.

```
prompt> optimize_routability -drc_rules {{ "Local double pattern cycle"
 "M2" }
{ "Diff net spacing" "{M2  M2}" } { "Diff net via-cut spacing" "{VIA1
 VIA2}" }
```

See Also

- get_drc_errors

Feedback

optimize_routes

Optimizes the routing to improve the routing patterns and increase the yield during manufacturing.

Syntax

status *optimize_routes*

```
[-max_detail_route_iterations num]
[-nets list [-reroute_all_shapes_in_nets true | false]]
```

Data Types

```
num     integer
list    list
```

Arguments

`-max_detail_route_iterations num`

Specifies the number of search and repair loops to run after optimization.

Router runs the specified number of detail route iterations if using *set_app_options -list {route.detail.force_max_number_iterations true}* command.

The default value is 40. The range is 0 to 1000.

`-nets list`

Specifies the nets to optimize.

If you do not specify this option, router selects a group of nets to optimize based on their routing patterns and the value from the *route.detail.optimize_wire_via_effort_level* application option.

`-reroute_all_shapes_in_nets true | false`

Controls whether all shapes on the specified nets are rerouted by the command, regardless of the existing routing patterns.

The option has an effect only when used with the *-nets* option; it is ignored if you do not use the *-nets* option.

The default value is false.

Description

This command performs detail route optimization. It detects nonoptimal routing patterns on signal nets and clock nets and tries to reroute them to improve the yield and minimize the wire length and via count. Router picks the nets to optimize based on their routing patterns and the optimize wire and via effort level, as specified by the *route.detail.optimize_wire_via_effort_level* application option.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example performs three search and repair loops after optimization.

```
prompt> optimize_routes -max_detail_route_iterations 3
1
```

The following example optimize nets N1, N2, and N3 by rerouting all of their shapes.

```
prompt> optimize_routes -nets {N1 N2 N3} \\
        -reroute_all_shapes_in_nets true
```

See Also

- route_detail
- route.detail.optimize_wire_via_effort_level

---

optimize_topology_plans

Optimizes topology plans in the current block for feedthroughs, pins and repeaters. Update the topology plans with Manhattanized edges which can be later used to guide structured bus routing and repeater insertion.

Syntax

status *optimize_topology_plans* [*topology_plan_list*] [*-repeaters_only*] [*-no_route*]

Data Types

topology_plan_list collection

Arguments

topology_plan_list

Specifies a list of topology plans to optimize. If omitted, the optimization is applied for all topology plans defined in current block.

-repeaters_only

Insert virtual register/buffer locations per net estimation rule. The command doesn't add new topology nodes or edges.

Feedback

-no_route

Create feedthroughs and pins based on the plan definition. In order to create feedthroughs in no_route mode, users need to define the topology plan with complete routing topology.

Description

The command *optimize_topology_plans* takes the topology plans as the guidance to route the corresponding bundle nets, honoring the topology plan associated net estimations rules, applicable non-default routing rules, individual, bundle, or block pin constraints (according to this said priority), create feedthroughs and pins.

The actual routing topology is then used to Manhattanize the topology edges.

If the topology plans' net estimation rules also define the buffer or pipeline register spacing distances, then the repeater optimization will be performed by adding topology repeaters along the topology edges according to the corresponding spacing rules. The repeater optimization is MIB, MPH and blockage aware.

The Manhattanized topology edges and the added topology repeaters can later be used for structured bus routing and repeater or pipeline register insertion.

The command returns 1 if successful; 0 otherwise.

Examples

The following example optimize all the topology plans in the current block:

```
prompt> optimize_topology_plans
```

See Also

- check_topology_plans
- create_topology_plan

Feedback

p

pack_macro_group

Pack macros in a macro group.

Syntax

```
status pack_macro_group
list_of_macro_groups
```

Data Types

list_of_macro_groups collection of macro groups

Arguments

`list_of_macro_groups`

Specifies a list of macro groups.

Description

This command is not intended for stand-alone use. It is intended only for use through Macro Placement Assistant GUI.

parallel_execute

Executes a list of read-only commands in parallel.

Syntax

status *parallel_execute*

```
[-commands_only]
[-list_allowed_commands]
[-max_cores count]
[command_list]
```

Data Types

```
count         integer
command_list  string
```

Feedback

Arguments

`-commands_only`

Specifies that all commands listed in the *command_list* argument are specified without a log file. The output of every command is written out after all commands have completed.

`-list_allowed_commands`

Lists all the allowed read-only commands supported by the *parallel_execute* command.

This option cannot be used with any other options or arguments.

`-max_cores` *`count`*

Specifies the maximum number of commands that can be executed concurrently at any given time. You can specify any positive integer greater than or equal to 1.

The default for this option is as specified by the *set_host_options -max_cores* command. If the *set_host_options -max_cores* command was not run, the default is 1.

When the maximum number of cores is 1, the command runs the specified commands sequentially.

If you use the *parallel_execute* command within the *redirect -bg* command, the specified value must be less than the value specified with the *-max_cores* option of the *redirect -bg* command. Otherwise, the maximum number of cores for the *parallel_execute* command is reduced to the maximum number of cores specified for the *redirect -bg* command.

`command_list`

Specifies the list of commands to execute in parallel. Use the following syntax to specify each command to run and the log file for its output:

`{`*`command`*`} log_file`

Each command must be specified on its own line. If the command has no options, the braces {} are optional.

Instead of creating a log file for each command, you can output the results for all of the commands to the console after all the commands complete by using the *-commands_only* option. In this case, do not specify a log file for each command.

Feedback

Description

The *parallel_execute* command provides a mechanism to easily execute a set of read-only commands in parallel on the same machine where the main process is running. The spawned commands access the same in-memory data for the same design. The parent process is blocked until the longest running command completes. To run the commands in parallel in the background, run the *parallel_execute* command with the *redirect -bg* command.

The commands must be independent of each other, must not change the design database, and are not inherently multithreaded, thereby saving time on their sequential execution. User-defined procedures can be executed; however, they must use only supported commands. The commands supported by the *parallel_execute* command are primarily reporting and querying commands. To list the supported commands, use the *-list_allowed_commands* option. Nested *parallel_execute* commands are not allowed.

If you specify unsupported commands, the *parallel_execute* command issues an error message and continues executing the remaining commands.

When you use this command consider the following guidelines:

- Some reporting commands perform a timing update internally if the design timing is not up-to-date. If these commands are executed in parallel, each command runs the timing update independently.

  To reduce runtime and memory usage, run the *update_timing* command before running the *parallel_execute* command.

- The spawned commands cannot pass variables back to the parent process.

  To pass variables from a child process to the parent process, you must write the contents of the variables to a file during the child process, and then read that file in the parent process.

- The *parallel_execute* command implicitly links the design if needed.

The *parallel_execute* command itself does not check out any license keys. The commands specified within *parallel_execute* check out licenses as required. A license key checked out in this way can be reused by all the other commands inside the *parallel_execute*. If the required keys are already checked out when you run the *parallel_execute* command, those keys are reused by the child commands inside *parallel_execute*, and no extra keys are checked out. If a command within *parallel_execute* checks out a license on its own, it checks it back in at the end of its invocation. Thus the status of licenses checked out before and after *parallel_execute* are the same.

Each spawned command is run in a single core. If the *parallel_execute* command fails to spawn a command, it executes the command sequentially after all other spawned commands have completed.

Feedback

In the following cases, the *parallel_execute* command runs the commands sequentially:

- There is only one command inside *parallel_execute*.
- The number of commands to run in parallel is set to 1 with the *-max_cores* option.

In these cases, there is not any parallelization. Single threading is not enforced and the number of licenses checked out is proportional to the *set_host_options -max_cores* value. If a command within *parallel_execute* checks out a license on its own, the license is not checked back in for these special cases.

Examples

The following example lists all allowed read-only commands.

```
prompt> parallel_execute -list_allowed_commands

Allowed read-only commands are:
- cmd1
- cmd2
 ...
```

The following example executes a single command and writes the output to the log file named log1. The command is directly executed, not spawned.

```
prompt> parallel_execute {
? {report_clock_qor -clocks [get_clocks test*]} log1
? }
? ? Only one command specified, running it in serial manner.
Running command : 'report_clock_qor -clocks [get_clocks test*]' > log1

All command runs are done. Below is the status.

Completed 'report_clock_qor -clocks [get_clocks test*]' successfully.
Output is in log 'log1'
```

The following example executes three commands by spawning them and writing out their output. The maximum number of concurrent commands is 5 as set by the *set_host_options* command.

```
prompt> set_host_options -max_cores 5
prompt> parallel_execute -commands_only {
? report_cells
? {report_site_defs -nosplit}
? {report_delay_calculation -from pin1 -to pin2}
? }
Dispatching command : 'report_cells'
Dispatching command : 'report_site_defs -nosplit'
Dispatching command : 'report_delay_calculation -from pin1 -to pin2'
Waiting for all dispatched commands to complete ...
Done.
```

Feedback

```
All command runs are done. Below is the status.

Completed 'get_cells' successfully.
Output given below:

**************************************
Report : cell
 ...

Completed 'report_site_defs -nosplit' successfully.
Output given below:

**************************************
Report : report_site_defs
 ...

Completed 'report_delay_calculation -from pin1 -to pin2' successfully.
Output given below:

**************************************
Report : delay_calculation
 ...
```

The following example is the same as the previous example except that only two commands can run in parallel.

```
prompt> parallel_execute -commands_only -max_cores 2 {
? report_cells
? {report_site_defs -nosplit}
? {report_delay_calculation -from pin1 -to pin2}
? }
```

---

parse_proc_arguments

Parses the arguments passed into a Tcl procedure.

Syntax

string *parse_proc_arguments* -args *arg_list result_array*

```
list arg_list
string result_array
```

Feedback

Arguments

`-args arg_list`

Specified the list of arguments passed in to the Tcl procedure.

result_array

Specifies the name of the array into which the parsed arguments should be stored.

Description

The *parse_proc_arguments* command is used within a Tcl procedure to enable use of the -help option, and to support argument validation. It should typically be the first command called within a procedure. Procedures that use *parse_proc_arguments* will validate the semantics of the procedure arguments and generate the same syntax and semantic error messages as any application command (see the examples that follow).

When a procedure that uses *parse_proc_arguments* is invoked with the -help option, *parse_proc_arguments* will print help information (in the same style as using *help -verbose*) and will then cause the calling procedure to return. Similarly, if there was any type of error with the arguments (missing required arguments, invalid value, and so on), *parse_proc_arguments* will return a Tcl error and the calling procedure will terminate and return.

If you didn't specify -help, and the specified arguments were valid, the array variable *result_array* will contain each of the argument values, subscripted with the argument name. Note that the argument name here is NOT the names of the arguments in the procedure definition, but rather the names of the arguments as defined using the *define_proc_attributes* command.

The *parse_proc_arguments* command cannot be used outside of a procedure.

Examples

The following procedure shows how *parse_proc_arguments* is typically used. The argHandler procedure parses the arguments it receives. If the parse is successful, argHandler prints the options or values actually received.

```
proc argHandler args {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo "  $argname = $results($argname)"
  }
}
define_proc_attributes argHandler -info "argument processor" \\
  -define_args \\
  {{-Oos "oos help" AnOos one_of_string {required value_help {values {a
 b}}}}
   {-Int "int help" AnInt int optional}
```

Feedback

```
   {-Float "float help" AFloat float optional}
   {-Bool "bool help" "" boolean optional}
   {-String "string help" AString string optional}
   {-List "list help" AList list optional}}
  {-IDup int dup AIDup int {optional merge_duplicates}}}
```

Invoking argHandler with the -help option generates the following:

```
prompt> argHandler -help
Usage: argHandler    # argument processor
        -Oos AnOos              (oos help:
                                 Values: a, b)
        [-Int AnInt]            (int help)
        [-Float AFloat]         (float help)
        [-Bool]                 (bool help)
        [-String AString]       (string help)
        [-List AList]           (list help)
```

Invoking argHandler with an invalid option causes the following output (and a Tcl error):

```
prompt> argHandler -Int z
Error: value 'z' for option '-Int' not of type 'integer' (CMD-009)
Error: Required argument '-Oos' was not found (CMD-007)
```

Invoking argHandler with valid arguments generates the following:

```
prompt> argHandler -Int 6 -Oos a
  -Oos = a
  -Int = 6
```

partition_block

Create a partitioned version of the current block based on a physical region.

Syntax

int *partition_block*

```
[-region region]
[-halo alo]
object
```

Data Types

```
region      polyrect
halo        distance
```

Feedback

Arguments

`-region` *region*

A required argument that specifies a rectilinear boundary from which to create a single partition block. Accepts both bbox and bounary coordinate list specifiers. This is a mandatory option.

`-halo` *halo*

An optional argument that specifies a halo or context buffer around each partition region. When given, each partition region extends by the halo distance on each side.

Description

The *partition_block* command creates a single clipped or partitioned block that captures a given region of the current block. The command saves the resulting partition block into a new library. The library has the name <current_lib>_partition_block, and if a library exists with the same name (from previous calls to *partition_block*) then a numerical suffix is appened to create a unique name. The partitioned block keeps the name of its source block.

The command accepts a rectilinear region, and an optional halo region. The effective partition area is the given region, exteneded on all sides by the halo value if specified. The resulting partition block contains the physical objects that intersect the partition area, along with the corresponding pieces of the netlist. A partition block is always a valid design, though not always a complete sub-circuit. The partition operation makes no additional edits to clean up incomplete states such as dangling nets, missing drivers, etc. Rather the partition block aims to be a most accurate copy of only the data present in the given partition region.

Examples

The following command creates a partition block using a bbox region

```
prompt> partition_block -region {{0 0} {10 10}}
```

The following example creates a partition block using a rectilinear region

```
prompt> partition_block -region {{5 5} {5 100} {100 100} {100 95} {10 95}
 {10 5}}
```

The following example creates a partition block with a halo

prompt> *partition_block -region {{0 0} {20 20}} -halo 2*

---

place_eco_cells

Performs coarse placement and legalization on ECO cells in the design.

Syntax

status *place_eco_cells*

```
-cells cell_objects | -unplaced_cells | -eco_changed_cells
[-no_legalize]
[-legalize_only]
[-channel_aware]
[-legalize_mode free_site_only | allow_move_other_cells |
 minimum_physical_impact]
[-displacement_threshold threshold]
[-max_displacement_threshold max_distance]
[-fixed_connection_net_weight weight]
[-honor_user_net_weight]
[-use_virtual_connection]
[-max_fanout max_fanout]
[-ignore_pin_connection pin_name_list]
[-remove_filler_references references]
[-displacement_tolerance_level low | high]
[-moveable_distance distance]
```

Data Types

```
cell_objects    collection
threshold       float
max_distance    float
weight          integer
max_fanout      integer
pin_name_list   list
distance        float
```

Arguments

`-cells cell_objects`

Places the group of specified cells. You must specify one of the *-cells*, *-unplaced_cells* and *-eco_changed_cells* options. These options are mutually exclusive with each other.

Feedback

`-unplaced_cells`

Places all unplaced cells. You must specify one of the *-cells*, *-unplaced_cells* and *-eco_changed_cells* options. These options are mutually exclusive with each other.

`-eco_changed_cells`

Places all the cells with the *eco_change_status* attribute with values *create_cell*, *add_buffer*, *change_link*, *size_cell*, or *add_buffer_on_route*. You must specify one of the *-cells*, *-unplaced_cells* and *-eco_changed_cells* options. These options are mutually exclusive with each other.

`-no_legalize`

Runs placement without legalizing the cells. Use this option when you must run *place_eco_cells* multiple times for different purposes, but legalization needs to be done only one time. By default, this option is off.

`-legalize_only`

Performs only legalization without placement on the user-provided cells, if you have decided the cell locations. This option is used only with the *-cells* or *-eco_changed_cells* option. The *-legalize_only* and *-no_legalize* options are mutually exclusive.

- If you specify the *-legalize_only -cells* option, the command applies to cells that already have locations, that is, the *is_placed* attribute is TRUE. When the option is specified, you need to supply locations for all input cells. If there is an unplaced cell, the command fails with a EPL-020 error.
- If you specify the *-legalize_only -eco_changed_cells* option, the command applies to cells with the *eco_change_status* attribute that has values *create_cell*, *add_buffer*, *change_link*, *size_cell*, or *add_buffer_on_route*, and the *is_placed* attribute as TRUE. The command skips the cells that are not placed with the warning message EPL-021.

  To perform only legalization without placement for the cells which have *is_placed* attribute set to false, you can change the cell status with the *set_attribute $cells physical_status placed* command before running *place_eco_cells*. Note that you need to make sure to supply locations for these cells, otherwise, you might get unexpected results.

`-channel_aware`

Uses the channel area between nonabutted macro for ECO placement. For example, buffer chain or pipeline registers can be placed by using those channel areas to produce a better placement result. By default, this option is off.

Feedback

`-legalize_mode free_site_only | allow_move_other_cells | minimum_physical_impact`

Specifies the legalization mode. The default is *free_site_only*. This option cannot be used with *-no_legalize*. *-legalize_mode minimum_physical_impact* can only be used with *-legalize_only*.

- *free_site_only*: The ECO cells are legalized on free sites without moving other existing cells.
- *allow_move_other_cells*: The ECO cells are legalized on the nearest legal locations with moving other existing cells.
- *minimum_physical_impact*: Combine ECO cell legalization (free sites only and push non-ECO cell away) into a single, minimum physical impact legalization. Legalize ECO cells on free sites without moving other existing cells first. If it succeeds, then do legalization with moving other existing cells for cells that exceeds displacement_threshold. This allows non-ECO cells to be pushed away to make space for ECO cells.

`-displacement_threshold` *`threshold`*

Specify the displacement threshold value. The units are microns and the value cannot be negative. This option cannot be used together with the *-no_legalize* option. This option cannot be used together with *-legalize_mode allow_move_other_cells*. When this option is used in different legalize mode, the behavior is different. The command will not legalize the cells whose legalization displacement will exceed the specified threshold. That is, the tool keeps the locations of those cells before legalization. And the tool reports the total number of the rejected cells due to the specified threshold and creates a collection *epl_legalizer_rejected_cells* to track these rejected cells. If the collection is already there before *place_eco_cells*, it will be reset. For the cells in the epl_legalizer_rejected_cells collection, you can use *legalize_placement* to push the non-ECO cells to make space for the ECO cells.

- *free_site_only*: The command will not legalize the cells whose legalization displacement will exceed the specified threshold. That is, the tool keeps the locations of those cells before legalization. And the tool reports the total number of the rejected cells due to the specified threshold and creates a collection called *epl_legalizer_rejected_cells* to track these rejected cells. If the collection is already there before running *place_eco_cells*, it will be reset. For the cells in the epl_legalizer_rejected_cells collection, you can use the *place_eco_cells -legalize_mode allow_move_other_cells -legalize_only* command to push the non-ECO cells to make space for the ECO cells.

Feedback

- *minimum_physical_impact*: The command first legalizes cells on free sites, but does not legalize the cells whose legalization displacement will exceed the specified threshold. And then collect these cells to do legalization with moving other existing cells again.

`-max_displacement_threshold` *`max_distance`*

Specify the maximum displacement threshold value. The units are microns and the value cannot be negative. This option must be used with the *-displacement_threshold* option. The threshold specified by the *-max_displacement_threshold* option should be greater than or equal to the threshold specified by the *-displacement_threshold* option. When this option is used in different legalize mode, the behavior is different. The command creates a collection called *epl_max_displacement_cells* to track the ECO cells which have a legalization displacement that exceeds the threshold specified by the *-max_displacement_threshold* option. If the collection already exists before this command run, it will be reset. The command also does not legalize the cells since the displacement of these cells also exceeds the threshold specified by the *-displacement_threshold* option. The collection *epl_max_displacement_cells* is a subset of the collection *epl_legalizer_rejected_cells*. For the cells in the collection *epl_max_displacement_cells*, you can decide to reject the ECO changes for these larger displacement ECO cells.

- *free_site_only*: The command creates a collection called *epl_max_displacement_cells* to track the ECO cells which have a legalization displacement that exceeds the threshold specified by the *-max_displacement_threshold* option. If the collection already exists before this command run, it will be reset. The command also does not legalize the cells since the displacement of these cells also exceeds the threshold specified by the *-displacement_threshold* option. The collection *epl_max_displacement_cells* is a subset of the collection *epl_legalizer_rejected_cells*. For the cells in the collection *epl_max_displacement_cells*, you can decide to reject the ECO changes for these larger displacement ECO cells.
- *minimum_physical_impact*: Tool will first legalize eco cells on free sites. If any eco cells has displacement greater than displacement_threshold, then depends on app option eco.placement.optimized_legalization, the behavior is different. If it is set to true (default), tool will try again to legalize those cells with larement displacement by allowing to move existing cells. If eco.placement.optimized_legalization is set to false, and there exists ecos cells whose legalization displacement exceed the specified max threshold, the legalization will failed. And the *epl_legalizer_rejected_cells* and *epl_max_displacement_cells* collections will be created to record cells according to their displacement as if the "on free site" legalization happened.

`-fixed_connection_net_weight` *`weight`*

Specify the net weight for net connected to fixed point, such as the I/O pad/ macro. The value is integer type and should be great than or equal to 2. The option cannot be used with *-legalize_only* and *-use_virtual_connection*.

The weight of net connected to the fixed point is set to the given value, while the weight of other nets is set to default value 1. *place_eco_cells* does coarse placement according to user-specified fixed connection net weight, and places the ECO cell close to the fixed point to which it connects directly. The net weight determines how close the ECO cell is to the fixed point.

The option can support virtual connection-based channel-aware coarse placement when you also specify *-channel_aware*.

`-honor_user_net_weight`

Performs placement based on user specified net weight setting. The option works together with two commands to create and get the user specified net weight: *set_eco_placement_net_weight* and *report_eco_placement_net_weight*.

The option cannot be used with *-legalize_only* and *-fixed_connection_net_weight*. The option can support channel-aware coarse placement when it used with the *-channel_aware* option.

User needs to set net weight by set_eco_placement_net_weight before place_eco_cells -honor_user_net_weight, otherwise, the command will error out.

`-use_virtual_connection`

Performs placement based on user-defined virtual connection. The option works together with a set of commands to create, modify and get the virtual connection: *create_virtual_connection*, *add_pins_to_virtual_connection*, *remove_pins_from_virtual_connection*, *remove_virtual_connections*, *"set_attribute -objects virt_conn_list -name name|weight|pins -value $value"*, *"get_attribute -objects virt_conn_list -name name|weight|pins"* and *get_virtual_connections*.

The option cannot be used with *-legalize_only* and *-fixed_connection_net_weight*. The option can support virtual connection-based channel-aware coarse placement when it used with the *-channel_aware* option.

This option must be used with the *-cells* option. The given cell must have at least one virtual driver and one virtual load. Such input cells are considered to be movable cells and placed by the *place_eco_cells* command. The given cell with only input or output virtual connection or without virtual connection will be considered as fixed cells and skipped to do *place_eco_cells* even if the cell exists in cell list of *-cells* option. The command issues a warning for such cells.

Feedback

If all given cells are skipped, the command errors out with no valid cell to be placed.

`-max_fanout` *`max_fanout`*

Specify the maximum fanout value to use when ignoring high-fanout net connections of the ECO cells being placed. The command ignores any net connected to the ECO cell if its fanout exceeds the maximum fanout specified. Since the placement of an ECO cell depends on its connectivity, the coarse placement result is affected by this option. However, there is no impact on legalization. If this option is used with the *-legalize_only* option, the command fails with a CMD-001 error message. If you do not specify this option, the tool uses a default of 100 for the maximum fanout.

`-ignore_pin_connection` *`pin_name_list`*

Specify the list of pin names, the connections to which should be ignored when placing ECO cells. The pin name must be the reference cell pin name. The pin can be on an ECO cell or on a fixed cell. The command ignores the connection of the specified pins for both eco cells and fixed cells. Since the placement of an ECO cell depends on its connectivity, the coarse placement result is affected by this option. However, there is no impact on legalization. If this option is used with the *-legalize_only* option, the command fails with a CMD-001 error message.

`-remove_filler_references` *`references`*

Specify the references of filler cells which can be ignored during Eco legalization. Unfixed filler cells of the specified references will be ignored and Eco cells can be placed in locations that overlap with these filler cells. And at the end of legalization, those filler cells overlapped with other cells will be removed. Other filler cells that not of the specified references are still treated as normal cells and cannot not be ignored during Eco legalization.

Fixed filler cells are always treated as normal cells and cannot be ignored even if their references are specified.

Since some filler cells may be removed, you may need to reinsert smaller filler cells to fill the space.

This option supports all three legalization modes. This option are mutually exclusive with -no_legalize.

`-displacement_tolerance_level low | high`

To be used with -legalize_mode minimum_physical_impact only. Specifies displacement tolerance level. The default is *low*. Specify users' tolerance level for eco cells displacements. WHen this option is used, minimum_physical_impact will be running with eco.placement.optimized_legalization true.

Feedback

- *low*: default value. Prefer minimum displacement of eco cells and toleartes more movements of existing cells to achieve it.
- *high*: It means the user can tolerate high displacement of eco cells and prefer minimum displacement of existing cells.

`-moveable_distance` *`distance`*

can only be used with -legalize_mode minimum_physical_impact or allow_move_other_cells mode. If this is not specified, all existing cells can be moved. If specified, only cells within this distance from eco cells haven't be legalized can be moved. This distance must be greater than 0.

Description

This command performs coarse placement and legalization on ECO cells in the design. ECO cells are a small number of cells that are passed into the command as a collection, or a small number of unplaced cells as a result of the *eco_netlist* or Tcl editing command runs. They can also be a small number of cells with the *eco_change_status* attribute that has the values *create_cell*, *add_buffer*, *change_link*, *size_cell*, or *add_buffer_on_route*. The attribute is set by the user or as a result of the *eco_netlist* or Tcl editing command runs.

This command legalizes the cells only on unoccupied sites in the neighborhood of the ECO cell location. The output of this command is a legally placed netlist. This command is designed for connectivity-based incremental ECO placement and provides the following features:

Ease of Use

This command places only the ECO cells and leaves other existing cells untouched to minimize the impact to the existing cell placements. It uses only free sites and does not push other cells away. You do not need to set other cells fixed.

The placement and legalization results from this command are user-controllable. You can select which cells for placement with the *-cells* option and legalize the cells with user-specified locations using the *-legalize_only* option.

Runtime

The runtime is far less than for full-chip placement.

QoR

The placement result is connectivity-aware, blockage-aware and macro- aware. After obtaining the initial location from the connectivity, the command adjusts the location to avoid the blockage or macro if needed.

Feedback

In general, the following cells are not considered as ECO cells. If they are specified, the command ignores them and issues an EPL-003 warning message:

- Hierarchical cell
- Fixed cell
- Macro cell
- Filler cell
- I/O pad cell
- Spare cell
- Physical only cell
- Cell without a signal net connection. Cells that connect only to tie nets are more like spare cells.

Using with the eco_change_status Attribute

By default, running the *place_eco_cells* command with or without the *-legalize_only* option resets the *eco_change_status* attribute to *eco_legalized*. However, when you run the command with the *-no_legalize* option, the *eco_change_status* attribute is reset to *eco_placed* for the eco_changed cells. For non eco_changed cells, the *eco_change_status* attribute remains the same. This reset operation is only needed when you legalize the ECO changed cells.

Legalization displacement report

During legalization, the tool reports legalization displacement summary as below.

```
****************************************
  Report : ECO Legalize Displacement
  Design : CORE
****************************************
avg cell displacement:    2.590 um ( 0.60 row height)
max cell displacement:    3.500 um ( 0.81 row height)
std deviation:            0.997 um ( 0.23 row height)
number of cell moved:         2 cells (out of 3 cells)
```

Flow usage about user specified net weight based coarse placement

```
open_block CORE
set_eco_placement_net_weight -nets $nets1 weight 2
set_eco_placement_net_weight -nets $nets2 weight 3

/* $net1 with weight 2, $net2 with weight 3, the others with default
 weight 1 */
place_eco_cells -cells $cellList -honor_user_net_weight

report_eco_placement_net_weight -output $file_name
```

Feedback

```
close_block
open_block CORE

/* load net weight setting file to memory */
source $file_name

/* change weight for $nets1 */
set_eco_placement_net_weight -nets $nets1 -weight 3

/* $net1 with weight 3, $net2 with weight 3, the others with default
 weight 1 */
place_eco_cells -honor_user_net_weight

/* reset all net weight */
set_eco_placement_net_weight -reset
```

Flow usage about virtual connection based coarse placement

- Step 1: Prepare the script to define virtual connection / netlist for target ECO cells. See the man page for *create_virtual_connection*. The target cell must have at least one virtual connection on both input and output pins.
- Step 2: Source the predefined script. The tool loads into memory the virtual connection based on the script.

  (for example, *source my_virtual_connection.tcl*)
- Step 3: Choose the target ECO cells on which to do coarse placement based on the virtual connection. The *num_of_virtual_connection* attribute records number of virtual connections to the ECO cell. The *create_virtual_connection*, *add_pins_to_virtual_connection*, *remove_pins_from_virtual_connection*, *remove_virtual_connections* and *"set_attribute -objects virt_conn_list -name name|weight|pins -value $value"* commands update the attribute value.

  (for example, *set theCells [get_cells -filter num_of_virtual_connection != 0 -hierarchical]*)
- Step 4: The *place_eco_cells* command builds the connection network and does coarse placement based on pure virtual connection. The command also does legalization. The command will not mix the virtual connection with real connection when building connectivity.

  (for example, *place_eco_cells -cells $cells -use_virtual_connection place_eco_cells -cells $cells -use_virtual_connection -no_legalize*)
- Step 5: Manually clean up the in-memory virtual connection data after cells are placed. The tool will clean up the in-memory virtual connection data automatically when the tool

Feedback

quits. When the tool is restarted, you must source the predefined script again to load the virtual connection data before running the *place_eco_cells* command.

(for example, *remove_virtual_connections -all*)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show how to run the *place_eco_cells* command with different cell specifications.

```
prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2}

prompt> place_eco_cells -unplaced_cells

prompt> place_eco_cells -eco_changed_cells
```

The following examples show how to use the *-no_legalize* option.

```
prompt> place_eco_cells -unplaced_cells -no_legalize

prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2}
 -no_legalize

prompt> place_eco_cells -eco_changed_cells -no_legalize
```

The following examples show how to use the *-legalize_only* option.

```
prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2}
 -legalize_only

prompt> place_eco_cells -eco_changed_cells -legalize_only
```

The following examples show how to use the *-channel_aware* option.

```
prompt> place_eco_cells -channel_aware -cells {STACK_BLK/NEW1
 STACK_BLK/NEW2}
```

The following examples show how to use the *-legalize_mode* option.

```
prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2}
 -legalize_mode free_site_only

prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2} \\
   -legalize_mode allow_move_other_cells

prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2} \\
   -legalize_mode allow_move_other_cells -legalize_only
```

Feedback

```
prompt> place_eco_cells -cells {STACK_BLK/NEW1 STACK_BLK/NEW2} \\
   -legalize_mode minimum_physical_impact -legalize_only
```

The following examples show how to use the *-displacement_threshold* option.

The cells for which the legalization displacement exceeds the specified threshold 10 micron are not legalized. The tool keeps the cell location before legalization and the cells are not moved.

```
prompt> place_eco_cells -cells $eco_cells -legalize_only
 -displacement_threshold 10

Example output:

Total 5 cells are not legalized since the legalization displacement
 exceeds
the specified threshold (e.g. > 10.000 um or 2 row height)
```

The cells for which the legalization displacement exceeds the specified threshold of 8.5 microns are not legalized. The tool keeps the cell location before legalization and the cells are moved to the location after coarse placement by *place_eco_cells*.

```
prompt> place_eco_cells -cells $eco_cells -displacement_threshold 8.5
```

The following examples show the large displacement report.

```
prompt> set legalize_displace_print_count_limit 20
prompt> set legalize_print_displacement_threshold 3
prompt> place_eco_cells -cells $eco_cells

Example output:

 Large displacement cells:
  Cell: CNTL_BLK/NEW2 (NAND2X1.FRAM)
    Input location: (0.000 0.000)
    Legal location: (1.680 12.960)
    Displacement: 13.068 um, e.g. 3.03 row height.
  Cell: CNTL_BLK/NEW3 (NAND2X1.FRAM)
    Input location: (0.000 0.000)
    Legal location: (3.360 12.960)
    Displacement: 13.388 um, e.g. 3.10 row height.

Total 2 cells has large displacement (e.g. > 12.960 um or 3 row height)
```

The following examples uses the *-max_displacement_threshold* option. The cells which legalization displacement exceeds the specified threshold 10 micron are not legalized. The tool creates two collections: epl_legalizer_rejected_cells and epl_max_displacement_cells.

```
prompt> place_eco_cells -cells $eco_cells -legalize_only \\
   -displacement_threshold 10 -max_displacement_threshold 20

Example output:
```

```
Total 5 cells are not legalized since the legalization displacement
 exceeds
the specified threshold (e.g. > 10.000 um or 2 row height)

Total 3 cells are physical-unfriendly ECO cells which displacement
 exceeds
the user specified threshold distance (e.g. > 20.000 um or 4 row height)
```

The following examples use the *-displacement_threshold* option with *-legalize_mode minimum_physical_impact*.

The cells for which legalization displacement exceeds the specified threshold 10 micron in "on free site" legalization will be legalized again with pushing non-ECO cells.

```
prompt> place_eco_cells -cells $eco_cells -legalize_only \\
   -legalize_mode minimum_physical_impact -displacement_threshold 10

Example output:

****************************************
  Report : ECO Legalize Displacement
  Design : CORE
****************************************
avg cell displacement:    2.590 um ( 0.60 row height)
max cell displacement:    3.500 um ( 0.81 row height)
std deviation:            0.997 um ( 0.23 row height)
number of cell moved:         2 cells (out of 3 cells)
```

The following examples use the *-max_displacement_threshold* option with *-legalize_mode minimum_physical_impact*.

The legalization fails if cells whose legalization displacement exceeds the specified max threshold 10 micron in "on free site" legalization are present.

```
prompt> place_eco_cells -cells $eco_cells -legalize_only \\
   -legalize_mode minimum_physical_impact \\
   -displacement_threshold 5 -max_displacement_threshold 10

Example output:

Error: minimum physical impact legalization failed due to physical
 unfriendly cells
```

The following examples use the *-fixed_connection_net_weight* option.

```
prompt> place_eco_cells -cells $cells -fixed_connection_net_weight 10
prompt> place_eco_cells -cells $cells -fixed_connection_net_weight 10
 -no_legalize
```

The following examples use the *-fixed_connection_net_weight* option with *-channel_aware*.

Feedback

```
prompt> place_eco_cells -cells $cells -fixed_connection_net_weight 5 \\
   -channel_aware
prompt> place_eco_cells -cells $cells -fixed_connection_net_weight 5 \\
   -no_legalize -channel_aware
```

The following examples show how to use the *-honor_user_net_weight* option.

```
prompt> place_eco_cells -cells $cells -honor_user_net_weight
prompt> place_eco_cells -cells $cells -honor_user_net_weight -no_legalize
```

The following examples use the *-honor_user_net_weight* option with *-channel_aware*.

```
prompt> place_eco_cells -cells $cells -honor_user_net_weight
 -channel_aware
prompt> place_eco_cells -cells $cells -honor_user_net_weight -no_legalize
 -channel_aware
```

The following examples show how to use the *-use_virtual_connection* option.

```
prompt> place_eco_cells -cells $cells -use_virtual_connection
prompt> place_eco_cells -cells $cells -use_virtual_connection
 -no_legalize
```

The following examples use the *-use_virtual_connection* option with *-channel_aware*.

```
prompt> place_eco_cells -cells $cells -use_virtual_connection
 -channel_aware
prompt> place_eco_cells -cells $cells -use_virtual_connection
 -no_legalize -channel_aware
```

The following examples show how to use the *-max_fanout* option.

```
prompt> place_eco_cells -unplaced_cells -no_legalize -max_fanout 500

prompt> place_eco_cells -unplaced_cells -max_fanout 500
```

The following examples show how to use the *-ignore_pin_connection* option.

```
prompt> place_eco_cells -unplaced_cells -no_legalize
 -ignore_pin_connection {CP}

prompt> place_eco_cells -unplaced_cells -ignore_pin_connection {CP A}
```

The following examples show how to use the *-remove_filler_references* option.

```
prompt> set libCells [get_lib_cells {lib1/FILL1 lib1/FILL2}]
prompt> place_eco_cells $ecoCells -remove_filler_references $libCells
```

The following example shows how to use the *-remove_filler_references* option in minimum_physical_impact legalization mode.

Feedback

```
prompt> place_eco_cells $ecoCells -legalize_mode minimum_physical_impact
 \\
    -remove_filler_references {FILL1 FILL2}
```

---

place_freeze_silicon

Places new engineering change order (ECO) cells by swapping out the spare cells. This command is typically used in the freeze silicon ECO flow.

Syntax

status *place_freeze_silicon*

```
[-cells cell_objects]
[-lib_cells_for_filler_recovery lib_cells]
[-no_spare_cell_swapping]
[-map_spare_cells_only]
```

Feedback

```
[-write_map_file map_file_name]
[-min_filler_distance distance]
```

Data Types

cell_objects	collection
lib_cells	collection
map_file_name	string
distance	distance

Arguments

`-cells` *cell_objects*

Specifies the ECO cells on which to do spare cell mapping. The given cells must have the is_fs_eco_add attribute as true and the eco_change_status attribute as one of the following:

- create_cell
- add_buffer
- add_buffer_on_route
- change_link
- size_cell

If this option is not used, the command does spare cell mapping for cells with the same is_fs_eco_add and eco_change_status attribute settings as the ECO cells.

`-lib_cells_for_filler_recovery` *lib_cells*

Specifies the programmable spare cell (PSC) filler library cells to recover unused space of fillers. When ECO cells are mapped to PSC fillers, there may be some unused white space between ECO cells, and these space need to be recovered as new PSC fillers. The command will only use the specified library cells to create new PSC fillers. If this option is not specified, the command will use all available PSC filler library cells in the reference libraries.

`-no_spare_cell_swapping`

Move eco cells to targeted spare cell locations without swapping spare cell (called trial map). This option is used to preview the mapping result and do analysis and remap eco cells if needed. The tool first runs a fast placement of the eco cells and then places each eco cell at its closest matching spare cell but doesn not do spare cell swapping. For any trial mapped cell pair (eco cell, spare cell), they are placed at the same location and the attribute *fs_mapped_cell_name* is used to record the mapping relationship. For eco cell, the attribute value is the trial mapped spare cell name and vice versa.

Feedback

The option can be used with the option *-cells*, *-map_spare_cells_only* and *-write_map_file*. This option also supports programmable spare cells.

`-map_spare_cells_only`

Perform spare cell mapping based on existing eco cell locations without fast placement for the eco cells. The tool just places each eco cell at its closest matching spare cell and swaps out spare cells. The option is used when you want to use the spare cells in the neighborhood of the given eco cells to do swapping. The option can be used after you apply -no_spare_cell_swapping and confirm that the eco cell locations are acceptable, or after you manually adjust the eco cell locations. The option can be used with the option *-cells* and *-no_spare_cell_swapping*. The option cannot be used with *-write_map_file* unless *-no_spare_cell_swapping* is also turned on. This option also supports programmable spare cells.

`-write_map_file` *`map_file_name`*

Writes out eco cell and spare cell mapping file, which is used with *map_freeze_silicon* command. This option alone will not trigger eco cell placement or spare cell mapping, and just writes out the mapping pairs (eco cell, spare cell) according to the attribute *fs_mapped_cell_name*. The command writes the mapping pair to the mapping file only when the eco cell and spare cell have the same location. If you manually move the eco cell after *-no_spare_cell_swapping*, the command disables the mapping pair and omits the pair from the mapping file. The option can be used with the option *-cells* and *-no_spare_cell_swapping*. The option cannot be used with *-map_spare_cells_only* unless *-no_spare_cell_swapping* is also turned on. This option also supports programmable spare cells.

`-min_filler_distance` *`distance`*

Specify the minimum distance between eco cells after mapping to PSC fillers. The unit of distance is micron, and this distance will be adjusted internally to be an integral multiple of the unit width of PSC fillers. If not specified, the default value is 0 and means no limitation on the spacing. This option only support eco cells with PSC type.

Description

The *place_freeze_silicon* command automatically places cell instances that were added during an ECO operation. The command does not move cells that are placed previously. Only new cells added by an ECO are placed.

By default, the tool maps new ECO cells with existing spare cells of the same reference library cell or maps them with existing programmable spare cells of the same PSC type.

The tool first runs a fast coarse placement for the ECO cells. Next, the tool finds spare cells nearby the ECO cells and then do matching between ECO cells and spare cells. The

Feedback

matching engine will match each ECO cell to its target spare cell as close as possible. Finally, the tool places each ECO cell to the location of its matched spare cell and swaps out the spare cell, and these cells swapped out will be deleted from database.

You can use an ECO routing command to complete the routing. The freeze silicon capability can be used to implement metal-only ECO changes on an existing layout.

If there are not enough spare cells, the command issues error message.

If there are programmable spare cell mapping rules set by command *set_programmable_spare_cell_mapping_rule*, the *place_freeze_silicon* will also honor these mapping rules and execute the specified mapping between eco cells and programmable spare cells. User can review the current mapping rules by using command *report_programmable_spare_cell_mapping_rule*. The mapping rules also can be removed by using command *remove_programmable_spare_cell_mapping_rule*. If you want that *place_freeze_silicon* does not honor any mapping rule, please remove all the mapping rules first.

The command behavior is the same, regardless of the design.eco_freeze_silicon_mode application option setting.

The option *-no_spare_cell_swapping* and *-map_spare_cells_only* allow user to analyze QoR before committing the spare cell mapping. And provide flexibility for user to manage spare cell mapping for the desired QoR. The user-driven freeze silicon QoR tuning flow is as follows. Additional iterations might be needed between step 3 and step 4.

1. Apply ECO changes.
2. Analyze eco cells and spare cells by *check_freeze_silicon* command.
3. Trial map eco cells to spare cells.
4. Do analysis and remap eco cells.
5. Map eco cells to spare cells.
6. PG and ECO Route.

For routability, you can mark spare cells in congested area as fs_dont_use before *place_freeze_silicon*, which prevents these spare cells from being used and might avoid a routing detour.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example maps the user-specified ECO cells, specified with the *-cells* option, to the near spare cells of the same reference library cell. Finally, the command swaps out the spare cells.

Feedback

```
prompt> place_freeze_silicon \\
   -cells [get_cells *eco_cell*]
```

The following example automatically maps all the newly added ECO cells to the near spare cells of the same reference library cell or the programmable spare cells (PSC) of the same PSC type. Finally, the tool swaps out the spare cells. The unused space from the PSC cells will be recovered by the same PSC-type library cells specified by *-cells* option.

```
prompt> place_freeze_silicon \\
        -lib_cells_for_filler_recovery {FILL1 FILL2}
```

The following 3 examples shows the usage of trial map eco cells to spare cells. You can preview the mapping result with *-no_spare_cell_swapping* and do analysis.

```
prompt> place_freeze_silicon -no_spare_cell_swapping \\
   -write_map_file my_map_file -cells $sorted_eco_cells
prompt> place_freeze_silicon -no_spare_cell_swapping \\
   -cells $sorted_eco_cells
prompt> place_freeze_silicon -no_spare_cell_swapping
```

The following 2 examples shows the usage of mapping eco cells to spare cells.

```
Manual spare cell mapping:
prompt> place_freeze_silicon -write_map_file my_map_file
prompt> map_freeze_silicon -map_file my_map_file

Batch mode mapping:
prompt> place_freeze_silicon -map_spare_cells_only
```

The following 2 examples shows the usage of *-no_spare_cell_swapping* and *-map_spare_cells_only*. When the option *-map_spare_cells_only* is used with *-no_spare_cell_swapping*, the *place_freeze_silicon* command will not run fast placement and not do spare cell swapping, just place each eco cell at its closest matching spare cell.

```
prompt> place_freeze_silicon -cells $sorted_eco_cells \\
   -no_spare_cell_swapping -map_spare_cells_only
prompt> place_freeze_silicon -cells $sorted_eco_cells \\
   -no_spare_cell_swapping -map_spare_cells_only -write_map_file
 my_map_file
```

The following example shows analysis and remap eco cells.

```
prompt> place_freeze_silicon -no_spare_cell_swapping \\
   -cells $sorted_eco_cells
```

Overlay congestion map and spare cells on GUI. Mark spare cells in congested area fs_dont_use.

```
prompt> set sC [get_selection]
prompt> set sp [filter_collection $sC "is_spare_cell == true" ]
prompt> set_attribute $sp fs_dont_use true
```

Feedback

```
prompt> place_freeze_silicon -no_spare_cell_swapping -cells
 $sorted_eco_cells
```

Evaluate the new trial mapping result and swap spare cell if the result is better.

```
prompt> place_freeze_silicon -map_spare_cells_only
```

Another example:

```
prompt> place_freeze_silicon -cells $sorted_eco_cells
 -no_spare_cell_swapping
```

Move eco cells to more feasible locations based on visual analysis.

```
prompt> place_freeze_silicon -cells $modified_eco_cells
 -map_spare_cells_only
```

The following example automatically maps the specified ECO cells with PSC type to the near programmable spare cells (PSC) of the same PSC type. And the size of space between the mapped eco cells will be larger than the specified distance 0.5.

```
prompt> place_freeze_silicon -cells $psc_eco_cells -min_filler_distance
 0.5
```

Feedback

place_group_repeaters

Performs on route placement of interconnect repeaters.

Syntax

status *place_group_repeaters*

```
-cells cell_list | -repeater_groups group_id_list
[-lib_cell_input pin_name]
[-lib_cell_output pin_name]
[-max_distance_for_incomplete_route distance]
[-first_distance distance]
[-last_distance distance]
[-blockage_aware]
[-horizontal_repeater_spacing spacing]
[-vertical_repeater_spacing spacing]
[-layer_cutting_distance layer_scale_list]
[-verbose]
[-check_prerequisite]
```

Data Types

cell_list	collection
group_id_list	list
pin_name	string
distance	float
spacing	integer
layer_scale_list	list

Arguments

`-cells` *cell_list*

Specifies list of repeaters to be placed in the repeater paths. The two options *-cells* and *-repeater_groups* are mutually exclusive, and one of them is required.

`-repeater_groups` *group_id_list*

Specifies list of repeater group IDs. The two options *-cells* and *-repeater_groups* are mutually exclusive, and one of them is required.

`-lib_cell_input` *pin_name*

Specifies the pin name when the library cell has multiple input pins. The default is D.

`-lib_cell_output` *pin_name*

Specifies the pin name when the library cell has multiple output pins. The default is Q.

Feedback

`-max_distance_for_incomplete_route` *distance*

Specifies the maximum gap or distance from driver pin to route, or from load to route. The input value must be greater than 0.

`-first_distance` *distance*

Specifies the distance between the driver and the first repeater. The default is 0.

`-last_distance` *distance*

Specifies the distance between the load and the last repeater. The default is 0.

`-blockage_aware`

Specified with distance-based options. The cells are automatically grouped and assigned cutlines. The computed cell location does not overlap with placement blockages, macros, or lower layer routes.

`-horizontal_repeater_spacing` *spacing*

Specifies the horizontal spacing between two adjacent repeaters in the horizontal direction in terms of number of site width. For example, if the width of repeater is 9 cell site, then the minimum horizontal spacing is 9. If you specify it to be less than 9, the tool automatically extends the spacing to 9. In this example, to achieve the checkerboard pattern, the horizontal spacing must be 9,13,17,21....

`-vertical_repeater_spacing` *spacing*

Specifies the vertical spacing between repeaters in the vertical direction in terms of number of site height. When cell is single site height, the minimum vertical spacing is 1 site height. In this example, to achieve a checkerboard pattern, the vertical spacing should be 1,5,9.... When you specify vertical spacing as 4, the tool automatically rounds it to 5. For a double site height library cell, to achieve a checkerboard pattern, you can specify 2,6,10....

`-layer_cutting_distance` *layer_scale_list*

Specifies the layer cutting distance list. Using this option, you can define input routes and output routes to cell center distances. Specify the option by using the following format: {{layer1 cutting_distance_in_1 cutting_distance_out_1} {layer2 cutting_distance_in_2 cutting_distance_out_2} ...}

`-verbose`

Shows each repeater path information including path driver, cells and loads.

`-check_prerequisite`

Performs a prerequisite check of the design. This is optional.

Feedback

Description

When *-check_prerequisite* is specified, this command will not place any repeaters. Only a prerequisite check of repeaters, supernet drivers, supernet loads, and supernet routes will be done.

When *-check_prerequisite* is not specified, this command performs on route placement of interconnect repeaters.

```
• Supports rule-based repeater placement with distance
(two pin supernets) and cutline (multiple fanout supernets).
• Performs smart self-organized (checkerboard) repeater placement based
 on your intent.
• Cuts routes and assign routes to associated repeater output net
after repeaters are placed.
• Supports generic repeater (not limited to register, buffer, or
 inverters).
```

For *place_group_repeater -cells*, the command applies distance-based repeater placement.

For *place_group_repeater -repeater_groups*, the command applies cutline-based repeater placement. Before running the *place_group_repeater* command, define the repeater groups, register path connections (virtual connection) for each set of repeater groups, and cutline for each repeater group by using the *set_repeater_group* command.

To define register path connections (virtual connection), specify the driver group, path drivers, or path loads for each repeater group, and specify the cells in sequence. The cell connection between groups depends on the cell order within the group.

For example, cell[0] in group 1 and cell[0] in its driver group 2 belong to one register path.

```
• For the first group, specify -path_drivers;
• For the middle groups, specify -driver_group_id;
• For the last group, specify -driver_group_id and -path_loads;
```

For *-repeater_groups* option, by default, this command depends on the group virtual connection to build cell connectivity. Each input group must have driver group (or path driver) and load group (or path load); otherwise, the command generates an error. If you need to depend on the real connection between cells, set the *eco.placement.eco_enable_virtual_connection* application option to false.

Examples

The following examples show the usages of command.

The following examples show the usages of *-cells* option.

```
prompt> place_group_repeaters -cells $ecoCells -lib_cell_input D
-lib_cell_output Q -max_distance_for_incomplete_route 3.0
```

Feedback

```
prompt> place_group_repeaters -cells $ecoCells -lib_cell_input D
 -lib_cell_output
Q -first_distance 20 -last_distance 50 -blockage_aware
```

The following examples show the usages of *-repeater_groups* option based on real connection.

```
prompt> set_repeater_group -group_id 1 -cells [get_cells {eco_cell_3
 eco_cell_7}]
-cutline {{720 366} {720 386}}
prompt> set_repeater_group -group_id 2 -cells [get_cells {eco_cell_2
 eco_cell_6}]
-cutline {{920 366} {920 386}}
prompt> set_repeater_group -group_id 3 -cells [get_cells {eco_cell_1
 eco_cell_5}]
-cutline {{1230 330} {1230 350}}
prompt> set_repeater_group -group_id 4 -cells [get_cells {eco_cell_0
 eco_cell_4}]
-cutline {{1430 330} {1430 350}}
prompt> set_app_options -name eco.placement.eco_enable_virtual_connection
 -value false
prompt> place_group_repeaters -repeater_groups {1 2 3 4} -lib_cell_input
 D
-lib_cell_output Q
```

The following examples show the usages of *-repeater_groups* option based on the user-defined virtual connection.

```
prompt> set_repeater_group -group_id 1 -cells $buf_group_1 -cutline {{250
  90} {250 105}}
-path_drivers $driver_pins
prompt> set_repeater_group -group_id 2 -cells $buf_group_2 -cutline {{190
 130} {205 130}}
-driver_group_id 1
prompt> set_repeater_group -group_id 3 -cells $buf_group_3 -cutline {{165
 155} {165 175}}
-driver_group_id 2
prompt> set_repeater_group -group_id 4 -cells $buf_group_4 -cutline {{110
 155} {110 175}}
-driver_group_id 3 -path_loads $load_pins_group_4
prompt> set_repeater_group -group_id 5 -cells $buf_group_5 -cutline {{135
 220} {150 220}}
-driver_group_id 3 -path_loads $load_pins_group_5
prompt> place_group_repeaters -repeater_groups {1 2 3 4 5} -verbose
```

The following examples show the usages of *-check_prerequisite* option.

```
prompt> place_group_repeaters -cells $cells -check_prerequisite
prompt> place_group_repeaters -repeater_groups {1 2 3}
 -check_prerequisite
```

Feedback

---

place_io

Places I/O driver cell instances.

Syntax

status *place_io*

```
[-io_guide io_guide_list]
[-rule rule_name]
[-matching_types matching_type_list]
[-pad_assignment_file filename]
[-include_unassigned_pads]
[-incremental]
[-skip_bump_assignment]
[-bump_assignment_only]
[-match_terminals_to_bumps]
```

Data Types

io_guide_list	list
rule_name	string
matching_type_list	list
filename	string

Arguments

`-io_guide` *io_guide_list*

Specifies the I/O guides in which to place I/O driver cell instances. Only drivers assigned to the specified I/O guides will be placed. Other drivers will be ignored and remain in their original locations. If no driver cells are assigned to the specified I/O guides, the command will do nothing. If this option is not specified, the command will place I/O drivers in all I/O guides as well as drivers not assigned to any I/O guide.

`-rule` *rule_name*

Specifies a single routing spacing rule for pathlines. If no rule is specified, the *place_io* command retrieves or creates a rule that satisfies the rules set for all RDL nets. If no rule is set on any RDL nets, the spacing rule is derived from the technology file. This option is used only for flip-chip designs.

Feedback

`-matching_types` *`matching_type_list`*

Specifies the matching types used during I/O placement. If this option is specified, only I/O driver cell instances specified in the matching types will be placed. Other drivers will be ignored and remain in their original locations. If this option is not specified, the command uses all existing matching types and places drivers not part of any matching type as well.

This option is only used for flip-chip designs since matching types describe relationship between bumps and pad pins. There exist two special types of matching types. The first type contains only bumps. These bumps are excluded from bump assignment and are not connected to any pad pins unless they have been connected to bumps in the original netlist by 2-pin nets. The second type of matching types does not contain any bump. The pads in such type of matching types will excluded from I/O placement. They remain at their current position and are not processed during bump assignment. Their RDL pins will not be connected to any bumps unless they have been connected to bumps in the original netlist by 2-pin nets. If a matching type contains both bumps and pad pins, the *place_io* command assigns bumps to pad pins according to the uniquify number. Excessive bumps or pad pins will remain unassigned.

When this option is selected, logical connectivity of pads that are not part of any specified matching types is not changed unless such pads are connected to bumps contained in the specified matching types. Under such a situation, the pads are disconnected from the bumps.

The creation of matching types enables bump assignment for macros whose design_type attributes are set as macro, not as pad or flip_chip_driver. Normally, because macro cell instances are not considered as I/O cells, no bumps are assigned to their RDL pins. To perform bump assignment for a macro, you must create a matching type that contains the RDL macro pins and bumps to be assigned to these pins. With such a matching type created, the *place_io* command assigns the bumps in the matching type to the pins in the matching type, with the ratio defined by the matching type uniquify number. User can also simply include the macro instance in the matching type. It is equivalent to include all macro RDL pins in the matching type. If user wants the bump to be connected to a specific macro pin terminal, the terminal must be included in the matching type.

When a pin has multiple terminals, only one is connected to the bump assigned. To force the tool to connect all, you must create a matching type with all terminals and the bump. In addition, the uniquify number of the matching type need to be set to the ratio of terminals to bumps.

`-pad_assignment_file` *`filename`*

Specifies allowable I/O guides for one or more I/O pads. Without such constraints, pads not assigned to I/O guides are placed within an I/O guide

Feedback

determined by the *place_io* command. You can limit the I/O guide candidates to a subset of all I/O guides.

The format of the constraint file is as follows. Each line contains one or more pad names followed by a list of I/O guide names. I/O guides not in the list cannot be used to place the pads in the line. If more than one pad is specified, they must be placed in a pair of curly braces. No curly braces are needed for I/O guides. Each line must end with a semicolon.

```
{pad1 pad2} guide1 guide2;
pad3 guide1 guide3 guide0;
```

`-include_unassigned_pads`

Assigns any unassigned or unconstrained I/O driver cells to an I/O guide and places the cells. If this option is not specified, the command does not place the unassigned or unconstrained drivers, unless you omit both the *-io_guide* and *-matching_types* options.

`-incremental`

Places I/O driver cells according to their spacing and offset attributes, only for nonflip-chip designs with no I/O constraints. The *place_io* command does not consider I/O guide dimension or bump cell distribution. I/O constraints are ignored with this option.

`-skip_bump_assignment`

If this option is used, the tool places IO pads only without performing bump assignment. This option and option "-bump_assignment_only" are mutually exclusive.

`-bump_assignment_only`

If this option is used, the tool does only bump assignment. No pad placement is done and I/O driver cells are not moved. The tool assigns bumps to I/O driver cells based on current locations of I/O driver cells. All the signal I/O constraints and power I/O constraints will be ignored in this mode. This option does not work with *-pad_assignment_file* option. This option and option "-skip_bump_assignment" are mutually exclusive.

`-match_terminals_to_bumps`

Matches each terminal of a pin to a bump cell. This option only works for pin terminals that fit the following requirements:

1. The label of the pin terminal must be "bump".
2. There is no one-to-one logical connection between the pin and a bump.

Feedback

If a pin has multiple terminals fitting these requirements, the tool assigns multiple bumps to the pin. For a pin that does not meet these requirements, the tool assigns bumps to the pin in the default way.

By default, the tool picks only one terminal of a pin that has the "bump" label and assigns one bump to the pin during I/O placement.

Description

This command places I/O driver cell instances in I/O guides. By default, I/O driver cell instances that are not assigned to an I/O guide are automatically assigned to available I/O guides and placed. All bumps are considered.

If any pad has a fixed status, it is not moved. In addition, you can also set signal I/O constraints to specify pad orders, pad locations, and space between pads. It is your responsibility not to introduce any constraint conflicts. For example, if the space between two fixed pads is described in a signal I/O constraint, the value must be equal to the actual space between the two fixed pads.

The orientation of a pad is determined by the orientation of its reference cell and the I/O guide which the pad is placed in. Specifically, if the pad is placed in an I/O guide with side set to bottom, its orientation is the same as that of the reference cell. If the pad is placed in I/O guides with different side values, the pad will be rotated in the same way as that of I/O guide with respect to a bottom guide. You can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, pad orientations will be changed accordingly. For example, if users set the reference_orientation to MY, a pad placed in a bottom guide will be y-axis flipped. The following command sets the reference_orientation to R270 for all pads whose ref_block attribute is the same as that of *pad1*. As a result, those pads will be rotated by 270 degrees clockwise.

This command ignores non-IO cells. This may cause an overlap between non-IO cells and IO pads. In case, such an overlap needs to be avoided the user can create matching types including all and only such non IO cells. The command will then treat all such non IO cells as regular IO pads and fix their position.

This command will delete all the unfixed fillers in the design.

```
prompt> set_attribute -name reference_orientation \\
   [ get_attribute -name ref_block [get_cells pad1]] -value R270
```

You can flip a pad along the direction perpendicular to the I/O guide of the pad. Specifically, you can set the is_flipped attribute as follows. This attribute can only be set on I/O cells placed during I/O placement.

```
prompt> set_attribute -name is_flipped -value true PAD1
```

Feedback

Examples

The following example places I/O drivers.

```
prompt> place_io
```

---

place_macro_ml

Apply machine learning to guide macro placer to achieve better results of congestion, tns, wns, wirelength, thermal and power for post-floorplan/optimization. The command uses distributed proceesing to explore lots of floorplans and then select the best floorplan by applying machine learning.

Syntax

status *place_macro_ml*

```
[-mode optimization_target]
[-effort optimization_effort]
[-style macro_placement_style]
[-host_options host_options]
[-work_directory directory_name]
[-on_edge_ratio on_edge_ratio]
[-incremental]
[-exploration_file exploration_file]
[-floorplan_file floorplan_file]
```

Data Types

```
optimization_target   string
optimization_effort   string
macro_placement_style   string
host_options   string
directory_name   string
on_edge_ratio   float
exploration_file   string
floorplan_file   string
```

Feedback

Arguments

`-mode` *`optimization_target`*

Specify optimization objective. Valid values are *congestion*, *tns*, *both*, *power*, *wirelength*, *wns*, *thermal*, and *all*. When *congestion* is specified, the command optimizes overall routing congestion. When *tns* is specified, the command optimizes TNS. When *both* is specified, the command optimizes both overall congestion and TNS. When *power* is specified, the command optimizes power consumption. When *wirelength* is specified, the command optimizes total wirelength. When *wns* is specified, the command optimizes WNS. When *thermal* is specified, the command optimizes thermal. When *all* is specified, the command optimizes congestion, TNS, and power consumption. Note that the option supports a list of optimization targets, meaning that multiple targets can be in the list. The default is *both*.

`-effort` *`optimization_effort`*

Specify optimization effort. Valid values are *low*, *medium* and *high*. For hierarchical designs, only effort medium is supported. The default is *medium*.

`-style` *`macro_placement_style`*

Specify macro placement style. Valid values are *on_edge*, *hybrid*, *freeform*, and *auto*. When the specified style is “auto”, the function explores both hybrid and freeform macro placement styles to optimize the design. For hierarchical designs, only style on_edge is supported. The default is *on_edge*.

`-host_options` *`host_options`*

Specify the host_options for distributed processing. This is a required option.

`-work_directory` *`directory_name`*

Specify the name of working directory for ML macro placement. The default is ./mlmp_dir.

`-on_edge_ratio` *`on_edge_ratio`*

To specify the ratio of macros that should be identified as on edge macros over all the available macros. This option is only for styles hybrid and auto. If the option is not set for hybrid or auto styles, the tool determines this value automatically. To know the value used by the tool, search for the text "On_edge ratio:" in the tool log file. To visualize what macros will be regarded as on edge macros for the specified value of on edge ratio option, use the identify_on_edge_macros -ratio command. This command identifies and highlights specific on edge macros (on the GUI) that are impacted by the macro placement depending on the ratio specified. This command can act as a guidance for you to get the best results for your design based on your requirements.

Feedback

`-incremental`

When the option is specified, the function uses incremental freeform engine as underlying engine to optimize designs. Only minor changes are made from existing macro placement when optimizing the design.

`-exploration_file` *`exploration_file`*

The option is used to specify customized exploration file. Users can specify customized app_options setting in the file such that the command will explore all the combinations in the file. Only freeform style is supported with the option.

`-floorplan_file` *`floorplan_file`*

The option is used to specify existing floorplan file. The command uses all the floorplans specified in the file associated with explored floorplan for ML prediction. The option supports styles on_edge and hybrid, not freeform and auto.

Description

This command applies machine learning to guide macro placer to achieve better results of congestion, TNS, and power for post-floorplan/optimization. The command uses distributed processing to explore lots of floorplans and then select the best floorplan using machine learning.

The following existing objects are removed in the command. PG routes, user routes, global routes. placement blockages. (can keep it using the app_options plan.macro.ml_keep_existing_placement_blockages) routing blockages. (can keep it using the app_options plan.macro.ml_keep_existing_routing_blockages) unlocked switch cells. unlocked cap and well tap cells.

Examples

The following example performs ML-based on_edge macro placement with medium effort to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp
```

The following example performs ML-based on_edge macro placement with medium effort to reduce both congestion and TNS using local machine.

```
prompt> set_host_options -name mlmp -max_cores 4 -submit_command "sh"
prompt> place_macro_ml -host_options mlmp
```

The following example performs ML-based hybrid macro placement with medium effort to reduce both congestion and TNS.

Feedback

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style hybrid
```

The following example performs ML-based auto-style macro placement with medium effort to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style auto
```

The following example performs ML-based freeform macro placement with medium effort to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style freeform
```

The following example performs ML-based hybrid macro placement with on_edge ratio 0.4 to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style hybrid -on_edge_ratio
 0.4
```

The following example performs ML-based on_edge macro placement with low effort to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -effort low
```

The following example performs ML-based hybrid macro placement with medium effort to reduce congestion, TNS, and power.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style hybrid -mode all
```

The following example performs ML-based on_edge macro placement with medium effort to reduce congestion.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -mode congestion
```

The following example specifies working directory named "ml_dir".

Feedback

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -work_directory "ml_dir"
```

The following example performs incremental ML-based macro placement to reduce both congestion and TNS.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -incremental
```

The following example performs auto style ML-based macro placement to reduce both wirelength and power.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -style "auto" -mode {wirelength
 power}
```

The following example performs ML-based macro placement with the customized exploration file.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -exploration_file
 explore_file.tcl

Below is an example of the exploration file.

plan.place.auto_create_blockages {soft partial}
plan.macro.auto_buffer_channels {true false}
plan.macro.group_shaping_effort {medium low}
```

The following example performs ML-based macro placement to reduce maxium temperature.

```
prompt> set_host_options -name mlmp -submit_command "qsub -P bnormal -l
 mem_free=30G" -max_cores 8
prompt> place_macro_ml -host_options mlmp -mode {thermal}
```

---

place_opt

Place and optimize the current design.

Syntax

place_opt

```
[-list_only]
[-from startStage]
[-to endStage]
```

Data Types

```
startStage   string
endStage     string
```

Arguments

`-list_only`

Prints out the major stages that constitute the default flow for the *place_opt* command.

These stages are: *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

This option cannot be used with the *-from* or *-to* options.

`-from startStage`

Specifies the starting stage for the *place_opt* command. Valid values are *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

The default is *initial_place*.

If you specify both the *-to* and *-from* options, the *startStage* stage cannot be preceded by the *endStage* stage in the order specified by the *-list_only* option.

`-to endStage`

Specifies the final stage for the *place_opt* command. Valid values are *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

The default is *final_opto*.

If you specify both the *-to* and *-from* options, the *startStage* stage cannot be preceded by the *endStage* stage in the order specified by the *-list_only* option.

Feedback

Description

The default behavior of this command (1) places the current design, (2) optimizes the placed design for timing, electrical DRC violations, area, power, and routability, (3) performs incremental placement to optimize timing and routability, (4) further optimizes the placed design, and (5) legalizes the design placement at the end.

Examples

The following example places and optimizes the current design and ends up with an optimized design with a legalized placement:

```
prompt> place_opt
```

The following example takes in a placed design as its input and optimizes it for timing, electrical DRC violations, power, area, and routability, without rerunning placement on it, and ends up with an optimized design with a legalized placement:

```
prompt> place_opt -from final_opto
```

See Also

- clock_opt

---

place_pins

Places pins on blocks within the current design or on the current block.

Syntax

status *place_pins*

```
[-cells cells]
[-nets nets]
[-pins pins]
[-ports ports]
[-exclude_nets nets]
[-nets_to_exclude_from_routing nets]
[-self]
[-legalize]
[-use_existing_routing]
```

Data Types

cells	collection
nets	collection
pins	collection
ports	collection

Feedback

Arguments

`-cells` *cells*

Specifies the blocks for pin assignment. Only the nets connected to the specified cells are routed during global routing and only pins on selected blocks are placed. By default, the command performs pin assignment on all blocks.

`-nets` *nets*

Specifies the nets for pin assignment. Only the specified nets are routed during global routing stage and only block pins connected to the selected nets are placed. By default, the command performs pin assignment on all nets.

`-pins` *pins*

Specifies the pins for pin assignment. Only the specified pins are placed when this option is used. The tool routes the nets that are connected to the specified pins but the tool skips feedthrough creation on those nets. So no feedthrough nets or pins are created or placed. By default, the command performs pin assignment on all block pins.

`-ports` *ports*

Specifies the top-level ports for pin assignment. The command places only the terminals associated with the specified ports. By default, the tool performs pin assignment on all block pins.

`-exclude_nets` *nets*

Specifies the nets that are excluded for pin assignment and feedthrough creation. All nets, except the excluded nets, are routed and pins are placed based on the routed nets. All the pins including feedthrough pins are placed except the pins that connected to those specified nets.

`-nets_to_exclude_from_routing` *nets*

Specifies the nets that are excluded from routing during pin placement. By default, the tool tries to route all the nets that are used for pin placement. This option can be useful if some nets are preferred to skip routing to get quick pin placement results on them. When this option is specified, the *place_pins* command performs pin placement based on net connectivity to minimize wire length. This option cannot be used with the option *-use_existing_routing* , since the routing is skipped when using that particular option.

`-self`

Performs pin placement on the top-level design. By default, pin placement is performed on blocks within the current top-level design.

Feedback

`-legalize`

Performs only pin legalization. The command runs in incremental mode (the value of app option *plan.pins.incremental* is ignored) and legalizes pin overlaps, pin shorts with pre-routes and off-track pins. Routing of nets is skipped, this can be used to quickly legalize existing pin placement. With this option pins that are already legal are not moved and pin shapes are not created for this pins/ports that do not already have shapes associated. That is only existing pins are legalized if needed. Existing pin shapes are considered legal if they are on edge, on track, do not have any overlaps and do not violate any technology related spacing constraints (like layer minimum spacing). Note that the app option to synthesize abutted pins is ignored during the legalize mode of the command.

This option cannot be used with the *-use_existing_routing* or the *-nets_to_exclude_from_routing* options.

`-use_existing_routing`

Uses existing global routing when placing pins. When this option is specified, the command *place_pins* expects that the nets of the relevant pins are routed by proper global routing commands already, for example, *route_global -virtual_flat* or *route_group -global_planning true*. These routing results will be removed after *place_pins* completes.

When this option is specified and no routing exists for a net, the locations of the relevant pins might not be optimal. The command *place_pins* will not try to route those nets. It will not calculate the flyline based location either.

Note that when running global route before *place_pins -use_existing_routing*, if the block pins already exist in the design, then the global router will route to those pre-existing pins. As a result, if pins are then placed by using these existing routing, their locations might have little or no changes.

Note that this option cannot be used with the *-pins* option.

Description

This command places pins on blocks within the current design, or the top ports of the current design, based on the command line options specified by user. If user does not specify the types of pins to be placed, it places pins for all the editable blocks without fixed physical pins within the current design.

The command first performs global routing, then places pins in legal locations on wire tracks based on the global routing results. The *place_pins* command does not use

Feedback

reserved tracks for pin placement. Depending on the type of pins to be placed, the wire tracks used are:

- For the top ports, *place_pins* uses wire tracks defined at the top.
- For the block pins, *place_pins* uses wire tracks defined inside the corresponding blocks. If the corresponding block does not have any wire tracks defined, then *place_pins* will use the wire tracks defined at the top.

Pin placement also honors pin constraints set by the *create_topological_constraints*, *set_individual_pin_constraints*, *set_bundle_pin_constraints*, and *create_block_pin_constraint* commands. The constraints set by those commands are therefore referred to as topological pin constraints, individual pin constraints, bundle pin constraints, and block pin constraints, respectively. These four types of pin constraints can also be defined in a pin constraints file, which can be read in by command *read_pin_constraints*.

If multiple pin constraints are applied to the same pins, normally the constraints are applied with the following priority:

- topological pin constraints
- individual pin constraints
- bundle pin constraints
- block pin constraints

However, for bundle pin constraints, if the option *-keep_pins_together* is set true, then *place_pins* will try to honor it whenever possible. In some cases, it might have to relax the individual pin constraints requested layer or spacing.

Certain types of pin constraints, e.g. spacing, location, layer, or pin length, can be specified as hard constraints by command *create_block_pin_constraint*. When these constraints are hard, *place_pins* honors the applicable value and skip all DRC rule checks, even if it means possible DRC violations. For example, if location is hard and one pin is constrained at a location inside pin blockage, or will be shorted to another pin, this pin will be placed at the location regardless. Or if length is hard and one pin is constrained by a pin length that is shorter than minimum length, or this value violates min area rule, the pin will still be of the specified length regardless these violations.

A pin guide or a routing corridor can be created to refrain certain pins within the defined region. Alternatively, a pin blockage can be created to forbid certain pins with in the defined region.

If pin constraints are so restrictive that *place_pins* cannot honor all of them, one or more constraints might be relaxed to place the constrained pins, provided they are not hard constraints. Depending on the type of constraint a pin has, the sequence of constraints relaxation can be slightly different.

Feedback

If the pin has the side and offset constraints, the constraints relaxation sequence is the following:

- If the pin has a non-zero range constraint such as offset range, pin guide, routing corridor, etc, then relax the spacing. Otherwise, relax the offset.
- Relax both offset and spacing.
- Ignore the edge abutment.

If the pin does not have the side and offset constraints, the constraint relaxation sequence is the following:

- Relax spacing.
- Ignore edge abutment but honor spacing.

If the preceding constraints relax sequence cannot find a solution to place the pin, the command tries additional relaxation sequence as follows:

- Relax offset but honor others.
- Relax layer but honor others.
- Relax spacing but honor others.
- Relax offset, layer and spacing.

During constraint relaxation, if any of the constraints are hard constraints, the corresponding relaxation is skipped.

The pin width, length and spacing can be affected by other factors in addition to the pin, bundle or block pin constraints, if they are not specified as hard constraints.

In particular, the pin width is decided by the applicable pin constraints applied to them according to the priority sequence above, with the following exceptions:

- if the pin is placed on a wire track with non-zero track width, then the pin width is the same as the track width. If the track width is less than the default width of the layer, the width is then promoted to the default width. All other width related pin constraints are ignored.
- if the pin has no width-related pin constraints, but its net has a non-default routing rule requiring a width on the layer, then the pin width is same as the non-default rule specified width
- if the pin has no width-related pin constraints and no non-default routing rule, then the pin width is the same as the maximum of the default width and min-width rule defined by the technology file

Feedback

The pin length is decided as the maximum of the pin length constraints (if applicable/ present) and the following:

- the pin width
- the min-length rule defined in the technology file on the layer if it is applicable
- the pin-length required to satisfy the min-area rule if there is a min-area rule defined in the technology file on the layer. Note that width based min-area rules are also supported, the maximum of the min-area rule and width-based min area rule will be applied if both are present.
- lastly, if the layer has the mask constraints defined, the pin length is promoted to 10X routing pitches

Note that the length of the pins after being determined as the maximum of the above mentioned constraints/values, is rounded up to the nearest multiple of the grid size (if grid is present). This is to ensure that pins are created on the manufacturing grid. The depth is rounded to nearest multiple of grid size that is greater than constrained depth.

If there is no individual or bundle pin spacing constraints, then the pin spacing is decided by the following:

- if its net has a non-default routing rule requiring a spacing distance on the layer, then the pin spacing to the nearest pin honors the specified distance
- if its net does not have a non-default routing rule or the non-default routing rule does not have a spacing distance requirement on the layer, then the pin spacing is decided by the command *create_block_pin_constraint*

The *set_editability* command can enable or disable this command for blocks or levels of physical hierarchy. The *place_pins* command has no effect on the blocks that are disabled by *set_editability*.

If feedthrough creation is allowed, this command might create feedthrough nets and ports, depending on the global routing results. If feedthroughs are created, the design netlist is modified. The newly-created feedthroughs are automatically updated with multivoltage (MV) constraints if the design uses UPF.

If feedthroughs pins/nets are created, by default, newly created feedthrough ports and nets are named "net_name__FEEDTHRU_#" in *place_pins*, where net_name is the name of the original net that connected this feedthrough port or feedthrough net, and "#" is an index number. The names of newly-created feedthroughs pins/nets can be controlled by following application options:

```
plan.pins.new_port_name_tag
plan.pins.new_port_name_tag_style
```

Use the following application option to control the split-net naming convention:

```
set_app_options -name plan.pins.new_split_nets_use_block_names -value
 true
```

When this application option is true, the tool inserts the feedthrough master block names into the feedthrough net name. The inserted string starts with master name of the driving block, then a sequence of all the load blocks master names separated by double underscore characters. By default, this application option is false by default and block names are not inserted into the feedthrough net name.

For example, if you are using suffix name tag style (default), the feedthrough net name is:

BaseNetName + "__" + BlockBasedSubString + "__" + NameTag + __ IndexNumber

For prefix name tag style:

NameTag + "_" + IndexNumber + "__" + BaseNetName + "__" + BlockBasedSubString

Note that this only applies to split nets that connect one block to one or more other blocks. It DOES NOT apply to any split net that has a top port connection in the block in which the split net belongs.

You can disable pin placement on an a previously-placed pin by setting the physical_status to "fixed" for the terminal of this pin. The following command sets this "fixed" status on terminal of pin block/A and pin placement skips placing this pin.

```
prompt> set_attribute [get_terminals -of_objects [get_pins block/A]]
 physical_status fixed
```

By default, pin placement tries to generate the global route and place pins so that block pins can be aligned for nets connecting two pins. To direct the tool to apply more effort to achieve better pin placement, use the *plan.pins.reserved_channel_threshold* application option.

By default, clock nets are excluded from feedthrough creation. To enable feedthrough creation on clock nets, set the *plan.pins.exclude_clocks_from_feedthroughs* application option to false.

When *-self* option is specified, the tool still places pins for the ports that are not marked as power/ground type but connected to power/ground net. When *-self* option is not specified and block pins are connected to top level power/ground net but the block port type are not power/ground, the tool still places pins for those block ports.

Users can use app options to control pin placement behavior. Specifically, pin placement related app options start with plan.pins. The following are current app options related to place_pins. For more details, use report_app_options plan.pins* to list those app options and their current settings.

Feedback

```
plan.pins.allow_pins_in_narrow_macro_channels
 plan.pins.exclude_clocks_from_feedthroughs
 plan.pins.exclude_inout_nets_from_feedthroughs
 plan.pins.incremental
 plan.pins.layer_range
 plan.pins.new_port_name_tag
 plan.pins.new_port_name_tag_style
 plan.pins.new_split_nets_use_block_names
 plan.pins.pin_range
 plan.pins.reserved_channel_threshold
 plan.pins.retain_bus_name
 plan.pins.synthesize_abutted_pins
 plan.pins.ignore_pin_spacing_constraint_to_pg
 plan.pins.treat_pg_as_shield
 plan.pins.enable_span_rules
```

If there are mask constraints defined on the tracks and if *place_pins* creates any pins on the mask constraints defined tracks, the mask constraints will also be set on the pins as the following:

- The mask constraint set on the pin is from one of the values set on the tracks. *place_pins* will not use any other values not seen on the current tracks.
- *place_pins* first checks the pins nearest usable tracks. A usable track is the track that is not occupied by this pin, and if there is a layer shape on this track with minimum width, it does not trigger the minimum spacing or any mask constraint spacing violation. The nearest usable tracks are those usable tracks on this pins left and right (or top and bottom) that are nearest.
- Then *place_pins* negates the mask constraints values on those nearest usable tracks. If there are common values between the negated mask constraints values on the left (or bottom) nearest usable track and the right (or top) nearest usable track, *place_pins* picks one value and applied it to this pin.
- If there are no common values between the negated mask constraints on the left (or bottom) nearest usable track and the right (or top) nearest usable track, *place_pins* chooses the mask constraint on the center track that this pin occupies and apply it to this pin. And a warning message shall be issued to the user that no applicable mask constraints values could be found.

This command returns 1 on success, 0 otherwise.

Examples

The following command places pins on all blocks within the current design.

```
prompt> place_pins
```

The following commands enable four cores for pin placement and perform pin placement on all blocks within the current design.

Feedback

```
prompt> set_host_options -max_cores 4
prompt> place_pins
```

---

pop_up_objects

Transfers physical, logical, and netlist objects from the block level to the top level.

Syntax

string *pop_up_objects*

```
[-cells block_instance_collection]
object_collection
```

Data Types

```
block_instance_collection collection
object_collection        collection
```

Arguments

`-cells block_instance_collection`

Specifies the block instances from which to pop-up objects. By default, all block instances are processed.

`object_collection`

Specifies the block-level objects to pop-up. The objects include nets, routing objects (paths, wires, vias and terminals), routing guides, placement blockages, pin guides, pin blockages buffers, physical only cell instances (that is, any cell whose related hierarchical blocks functionalities are not affected by the pop-up), bump regions, site rows, site arrays, or the owner hardmacro cells of the marker layer shapes, edit groups, and bump regions(see the *set_pop_up_object_options* command for the options that you can set for

Feedback

the *pop_up_objects* command). For example, if *net_collection* is included with *object_collection*, the *pop_up_objects* command pops up routing objects associated with the specified nets. Note that via matrix is always popped up with its owner net. So, if and only if you specify the owner net in the *net_collection*, the via matrix can be popped up.

The *object_collection* option is required for the *pop_up_objects* command.

Description

This command transfers objects from the block level to the top level.

If the *set_pop_up_object_options -pins_as_terminals true* is used and the *pop_up_objects* command is executed, the top-level terminals that match exactly the block pin shapes (block terminals) are created. If and only if the top level has a logical port associated with the top-level net that connects to the block pins. Only block terminals or block level nets can be specified as the objects to be popped up. If other objects are used (that is, block route shapes), no terminals are created.

If a block-level net is specified for pop-up, then all routing objects are popped up. To pop-up only specific routes (shapes or vias) of a block net, create a collection of the required objects and pass them to the *pop_up_objects* command.

If the specified net for pop-up is inside of a block that has multiple instances of multiply instantiated blocks (MIB), then if any of the instances do not have net connection for the port related to the net, then no routing is popped up for that instance.

If routing blockages or placement blockages in a block are the result of pushing down cells or routing as blockages, then these blockages cannot be popped back to the top. They will have the "copied-down" shadow status, and no objects with this shadow status may be popped back to the top. For example, if you set block_action as create_blockage for the cells while pushing down, the push_down_objects command creates a placement blockage in the child block, which cannot be popped up.

If a site row or a site array is specified for pop up, it will be copied to top level, and all wire tracks in its owning block will also be copied. If block action is remove, the specified row/array will be deleted. If top action is specified to merge, all original site rows/arrays and wire tracks on top level will be curved out by the boundary of the owning block.

Attributes are copied from the corresponding block-level object for all objects created at the parent level.

Examples

The following example pops up the power and ground net routing objects.

```
prompt> set_pop_up_object_options -object_type pg_routing
 -pins_as_terminals
prompt> set pg_nets [get_nets {blockA/VDD blockA/VSS}]
prompt> pop_up_objects $pg_nets
```

Feedback

The following example pops up cell instances from blockA.

```
prompt> set pop_cells [get_cells {blockA/U1 blockA/U2}]
prompt> pop_up_objects $pop_cells
```

The following example pops up signal routing objects (using an alternate way of specifying block-level objects for pop-up, that is, by specifying an entire net rather than an object collection):

```
prompt> set_pop_up_object_options -object_type signal_routing
 -pins_as_terminals
prompt> set pop_nets [get_nets blockA/netA]
prompt> pop_up_objects $pop_nets
```

See Also

- remove_pop_up_object_options
- report_pop_up_object_options
- set_pop_up_object_options

---

pre_extract

Perform pre-extraction process on a given block.

Syntax

string *pre_extract*

```
[-block block]
[-label label]
```

Data Types

block	string
label	string

Arguments

`-block` *block*

Specifies the block (design) to be pre-extracted. The default is the current block.

`-label` *label*

Specifies the label the resulting pre-extracted block will use. The default is "pre_extraction".

Feedback

Description

This command performs pre-extraction processing on the given block. If successful a new block of the same name under the given label is produced. The pre-extraction block contains shapes and vias pre-extracted according to technology rules. Extraction tools and engines are able to do higher-precision RC analysis on pre-extraction blocks.

Examples

The following example pre-extracts the current block:

```
prompt> pre_extract
```

The following example pre-extracts the "MY_TOP" block (design), using the "PRE_EXTRACT_1" label:

```
prompt> pre_extract -block MY_TOP -label PRE_EXTRACT_1
```

---

preplace_group_repeaters

Places interconnect repeaters without routes

Syntax

```
status preplace_group_repeaters
-repeater_group_locations repeater_group_location_list
```

Data Types

```
repeater_group_location_list                list
```

Arguments

`-repeater_group_locations` *repeater_group_location_list*

Specifies the list of repeater group placing information. The format of *repeater_group_location_list* is { {cell_collection, layer, location, potential routing direction, placing order} ...} or { {group_id, layer, location, potential routing direction, placing order} ...}. When using *group_id* attribute, you must define repeater group ID before applying this command. When *group_id* is specified, the command sorts the cells in a group, based on the driver pin physical location. The location is a point location for placing the cell collection or the group. The routing direction can be specified as north, south, east, west. The placing order can be specified as ascending or descending, default is ascending. The ascending means placing the cells in a group from the lowest track to highest track or from left-most available track to right-most track.

Feedback

Description

This command places the group repeaters before the routing. This command places the group repeaters either in an ascending or descending order, default is ascending. The ascending order means that the command places the cells in a group from the lowest or left-most available track to the highest or right-most track.

A FAA-Base-Beta license is required to run this command.

Examples

The following examples show the usages of command when using cell collections.

```
prompt> preplace_group_repeaters \\
-repeater_group_locations { { $cellGroup1, M2, {720 363.5}, north,
 descending} \\
{$cellGroup2, M2, {920 363.5}, east, ascending}\\
{$cellGroup3, M2, {1230 328.5}, east, ascending} {$cellGroup4, M2, {1430
 328.5}}, east}
```

The following examples show the usages of this command when using group IDs.

```
prompt> preplace_group_repeaters \\
-repeater_group_locations { { 1,M2, {720 363.5}, south, ascending} \\
{2, M2, {920 363.5},west,  ascending} {3, M2, {1230 328.5}, south,
 ascending}\\
{4, M2, {1430 328.5}, west, descending}}
```

---

preview_dft

Runs DFT Architect Only.

Syntax

```
status preview_dft
[-estimate_chains_with_max_length]
```

Arguments

`-estimate_chains_with_max_length`

Enables estimation-only flow and prints the required number of chains per test mode in each DFT partition based on user-specified max_length and other scan/

Feedback

wrapper related mixing constraints. Scan architecting is not run when this option is enabled, so detailed scan chain content is not printed due to which estimation is much faster than the regular preview_dft.

Description

Previews, but does not implement, scan chains, DFT signals connections and the on-chip clocking control logic to be added to the current design.

Examples

```
prompt> set_dft_signal -type ScanEnable -port SE
prompt> set_dft_signal -type TestMode -port TM
prompt> set_dft_signal -type ScanDataIn -port si*
prompt> set_dft_signal -type ScanDataOut -port so*
prompt> create_test_protocol
prompt> set_scan_configuration -chain_count 2
prompt> set_scan_compression_configuration -chain_count 20 -input 6
 -output 6
prompt> preview_dft
preview_dft

---

print_message_info

Prints information about diagnostic messages that have occurred or have been limited.

Syntax

string *print_message_info*

```
[-ids id_list]
[-summary]
```

Data Types

```
id_list      list
```

Feedback

Arguments

`-ids` *id_list*

Specifies a list of message identifiers to report. Each entry can be a specific message or a glob-style pattern that matches one or more messages. If this option is omitted and no other options are given, then all messages that have occurred or have been limited are reported.

`-summary`

Generates a summary of error, warning, and informational messages that have occurred so far.

Description

The *print_message_info* command enables you to print summary information about error, warning, and informational messages that have occurred or have been limited with the *set_message_info* command. For example, if the following message is generated, information about it is recorded:

Error: unknown command 'wrong_command' (CMD-005)

It is useful to be able to summarize all recorded information about generated diagnostic messages. Much of this can be done using the *get_message_info* command, but you need to know a specific message ID. By default, *print_message_info* summarizes all of the information. It provides a single line for each message that has occurred or has been limited, and one summary line that shows the total number of errors, warnings, and informational messages that have occurred so far. If an *id_list* is given, then only messages matching those patterns are displayed. If *-summary* is given, then a summary is displayed.

Using a pattern in the *id_list* is intended to show a specific message prefix, for example, "CMD*". Note that this does not show all messages with that prefix. It shows only the messages that have occurred or have been limited.

Examples

The following example uses *print_message_info* to show a few specific messages:

```
prompt> print_message_info -ids [list "CMD*" APP-99]

Id               Limit    Occurrences   Suppressed
-------------------------------------------------------
CMD-005              0              7            2
APP-99               1              0            0
```

At the end of the session, you might want to generate some information about a set of interesting messages, such as how many times each occurred (which includes

Feedback

suppressions), how many times each was suppressed, and whether a limit was set for any of them. The following example uses *print_message_info* to get this information:

```
prompt> print_message_info

Id                Limit    Occurrences   Suppressed
-------------------------------------------------------
CMD-005               0             12            0
APP-027             100            150           50
APP-99                0              1            0

Diagnostics summary: 12 errors, 150 warnings, 1 informational
```

Note that the suppressed count is not necessarily the difference between the limit and the occurrences, since the limit can be dynamically changed with the *set_message_info* command.

---

print_suppressed_messages

Displays an alphabetical list of message IDs that are currently suppressed.

Syntax

string *print_suppressed_messages*

Arguments

The print_suppressed_messages command has no arguments.

Description

The *print_suppressed_messages* command displays all messages that are suppressed using the *suppress_message* command. The messages are listed in alphabetical order. You can suppress informational, warning and error messages. The result of *print_suppressed_messages* is always an empty string.

Feedback

Examples

The following example shows the output from the print_suppressed_messages command:

```
prompt> print_suppressed_messages
No messages are suppressed

prompt> suppress_message {XYZ-001 CMD-029 UI-1}

prompt> print_suppressed_messages
The following 3 messages are suppressed:
CMD-029, UI-1, XYZ-001

Display the message IDs with suppressed patterns.

prompt> suppress_message {CMD-005 CMD-010} -pattern pin1
Information: Filtering out any 'CMD-005' tagged output containing pattern
 'pin1' (MSG-3446)
Information: Filtering out any 'CMD-010' tagged output containing pattern
 'pin1' (MSG-3446)

prompt> suppress_message CMD-005 -pattern pin2

prompt> suppress_message {NDMUI-001 CMD-001}

prompt> print_suppressed_messages
The following 4 messages are suppressed:
CMD-001, CMD-005 (with patterns { {pin1}  {pin2} }), CMD-010 (with
 pattern {pin1}), NDMUI-001
```

- suppress_message
- unsuppress_message

---

printenv

Prints the value of environment variables.

Syntax

string *printenv*

```
[variable_name]
```

Data Types

```
variable_name      string
```

Feedback

Arguments

variable_name

Specifies the name of a single environment variable to print.

Description

The *printenv* command prints the values of the environment variables inherited from the parent process or set from within the application with the *setenv* command. When no arguments are specified, all environment variables are listed. When a single *variable_name* is specified, if that variable exists, its value is printed. There is no useful return value from *printenv*.

To retrieve the value of a single environment variable, use the *getenv* command.

Examples

The following examples show the output from the *printenv* command:

```
prompt> printenv SHELL
/bin/csh

prompt> printenv EDITOR
emacs
```

See Also

- getenv
- setenv

---

printvar

Prints the values of one or more variables.

Syntax

string *printvar*

```
[pattern]
[-user_defined | -application]
```

Data Types

```
pattern      string
```

Feedback

Arguments

pattern

Prints variable names that match *pattern*. The optional *pattern* argument can include the wildcard characters * (asterisk) and ? (question mark). If not specified, all variables are printed.

-user_defined

Shows only user-defined variables. This option is mutually exclusive with the *-application* option.

-application

Shows only application variables. This option is mutually exclusive with the *-user_defined* option.

Description

The *printvar* command prints the values of one or more variables. If the *pattern* argument is not specified, the command prints out the values of application and user-defined variables. The *-user_defined* option limits the variables to those that you have defined. The *-application* option limits the variables to those created by the application. The two options are mutually exclusive and cannot be used together.

Some variables are suppressed from the output of *printvar*. For example, the Tcl environment variable array *env* is not shown. To see the environment variables, use the *printenv* command. Also, the Tcl variable *errorInfo* is not shown. To see the error stack, use the *error_info* command.

Examples

The following command prints the values of all of the variables:

```
prompt> printvar
```

The following command prints the values of all application variables that match the pattern *sh*a**:

```
prompt> printvar -application sh*a*
sh_arch                  = "sparcOS5"
sh_command_abbrev_mode   = "Anywhere"
sh_enable_page_mode      = "false"
sh_new_variable_message  = "false"
sh_new_variable_message_in_proc = "false"
sh_source_uses_search_path = "false"
```

The following command prints the value of the *search_path* variable:

```
prompt> printvar search_path
search_path              = ".  /designs/newcpu/v1.6  /lib/cmos"
```

Feedback

The following command prints the values of the user-defined variables:

```
prompt> printvar -user_defined
a                    = "6"
designDir            = "/u/designs"
```

---

proc_args

Displays the formal parameters of a procedure.

Syntax

string *proc_args*

proc_name

Data Types

proc_name string

Arguments

proc_name

Specifies the name of the procedure.

Description

The *proc_args* command is used to display the names of the formal parameters of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command *info* with the *args* argument.

Examples

This example shows the output of *proc_args* for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }

prompt> proc_args plus
a b

prompt> info args plus
```

Feedback

```
a b

prompt>
```

See Also

- proc_body

---

proc_body

Displays the body of a procedure.

Syntax

string *proc_body*

```
        proc_name
```

Data Types

```
proc_name       string
```

Arguments

proc_name

Specifies the name of the procedure.

Description

The *proc_body* command is used to display the body (contents) of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command *info* with the *body* argument.

Examples

This example shows the output of *proc_body* for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }

prompt> proc_body plus
 return [expr $a  + $ b]

prompt> info body plus
 return [expr $a  + $ b]

prompt>
```

Feedback

- proc_args

---

promote_clock_data

Loads specific clock data from a lower-level of hierarchy at the top level.

Syntax

integer *promote_clock_data*

```
[-cells block_instance_names]
[-auto_clock connected | local | all]
[-balance_points]
[-mesh_annotations]
[-port_latency]
[-latency_offset]
[-clocks top_clock_names]
[-force]
```

Data Types

block_instance_names	list
top_clock_names	string

Arguments

`-cells` *block_instance_names*

Specifies a list of names of the block instances from which to load specific clock data.

If this option is not specified, the data is promoted from all block instances in bottom-up order of their respective physical hierarchy level.

`-auto_clock connected | local | all`

Associates clocks at the block-level with clocks at the top-level. Before promoting balance points, it is necessary to associate clocks at the block-level with clocks at the top-level. For example, your top-level clock might be called "SYS_CLK", and the same clock in the block might be called "CLK". You can set the association between block clock and top clock by using the *set_block_to_top_map* command, or by using *promote_clock_data -auto_clock* and specifying the same rule. See the *set_block_to_top_map* man page for more details.

Feedback

You can select one of three rules for auto clock mapping:

- *connected* - The "connected" rule associates block-level clocks with top-level clocks under the following conditions: If a block clock has its source at a block port (a boundary clock), it can be associated to a top-level clock that propagates to that port. If a block clock has its source on an internal pin sources (a local clock), the top-level clock source must be declared at the same pin.
- *local* - The "local" rule maps connected clocks. In addition, if a block clock has its source on an internal pin sources (a local clock) and has no associated top-level clock, a new top-level clock is created with the same waveform as the block-level clock. The new top-level clock is associated with the local block-level clock.
- *all* - The "all" rule maps clocks as in the "local" rule. In addition, if a block clock has its source at a block port (a boundary clock) and no top-level clock propagates to that port, a new top-level clock is created with the same waveform as the block-level clock. The new top-level clock is associated with the local block-level clock. The top-level boundary clock allows timing analysis to be done, but it is not necessarily correct for signoff. You should consider removing or replacing this clock before signoff.

Note that if two block-level clocks are declared at the same boundary port, the "all" rule cannot resolve both of them. This is because it does not automatically declare two conflicting clocks in the top-level block. You must manually declare two top-level clocks, with the appropriate waveforms. After the top clocks exist, *-auto_clock* mapping can associate them with the block clocks.

`-balance_points`

Promotes balance points set by the *set_clock_balance_points* command.

This option is mutually exclusive with *-mesh_annotations*, *-port_latency* and *-latency_offset* options.

`-mesh_annotations`

Promotes the annotations set by the *set_annotated_delay* and *set_annotated_transition* commands.

This option is mutually exclusive with *-balance_points*, *-port_latency* and *-latency_offset* options.

`-port_latency`

Promotes latency inside the blocks and sets as balance points on the clock input pins of the block.

Feedback

This option is mutually exclusive with *-balance_points*, *-mesh_annotations* and *-latency_offset* options.

`-latency_offset`

Promotes offset latency at clock network sink and clock pins of integrated clock gating cells.

This option is mutually exclusive with *-balance_points*, *-mesh_annotations* and *-port_latency* options.

`-clocks`

Promotes only the given top-level clocks. Promotes all top-level clocks across modes whose clock names match with the clock list specified. Any clock independent exceptions present are also promoted.

`-force`

Allows the tool to promote constraints for clocks or modes or corners, which are mapped correctly skipping the unmapped clocks or modes or corners. Without this option, even if there is a mapping error or warning for single clock or active mode or active corner at the top-level,the constraints of other mapped clocks or active modes or active corners are also not promoted.

Description

The *promote_clock_data* command applies specific clock data from lower levels of physical hierarchy to the top level. The data include mesh annotations set using *set_annotated_delay* and *set_annotated_transition* commands, clock tree synthesis balance points set using *set_clock_balance_points* command, latency inside the blocks at the clock input pins and offset latency at clock network sink and clock pins of integrated clock gating cells. This promoted data is added to any data that are already applied to the top-level design.

You should use this command when:

- The annotations and balance points of a lower level block have changed locally and you want to see these data during top-level analysis.
- You have changed the design view of your lower-level block from "abstract" to "design", and your current data only cover the abstract part of the block.
- You need the latency inside the concurrent clock and data done blocks to be visible to the top-level.

The *promote_clock_data* command includes analysis of your block's current configuration, where a configuration is defined by the view type ("design" or "abstract") that you have linked for your block's subblocks. It is possible that your current block configuration is bigger than the configuration of your block at the time balance points and annotations were saved on disk. That is, the balance points and annotations on disk might only cover

Feedback

a portion of the instances and nets in your current block. This happens when your balance points and annotations on disk cover only an "abstract" view and your current design contains a full "design" view. In this case, *promote_clock_data* detects the problem and prints an error message.

When multiple instances from different levels of physical hierarchy are specified using *-cells* option, the data is promoted from the block instances in bottom-up order of their respective physical hierarchy level.

This command returns 1 on success, 0 otherwise.

Examples

The following example promotes mesh annotations from block instance "block1".

```
prompt> promote_clock_data -cells block1 -mesh_annotations
```

The following promotes balance points from all physical hierarchies.

```
prompt> promote_clock_data -balance_points
```

---

propagate_3d_connections

Derives logical connections for bumps in a 3DIC design.

Syntax

status *propagate_3d_connections*

```
[-nets net_list]
[-check_only]
[-no_port_punching]
[-set_terminals_for_updated_ports]
[-port_naming_style naming_style]
[-net_naming_style naming_style]
```

Feedback

Data Types

net_list	list
naming_style	string

Arguments

`-nets` *net_list*

Specifies the nets for logical connection propagation. By default, all top-level nets in the design are propagated.

`-check_only`

Check only physical and logical connectivity, do not perform propagation. By default, the command propagates logical connections.

`-no_port_punching`

Do not allow port punching.

`-set_terminals_for_updated_ports`

Set terminals for updated ports.

`-port_naming_style` *naming_style*

Specify the naming style of new created ports. The option string contains the desired format of the new ports. The possible keywords are:

- *%s*: the original name • *%d*: integer to uniquify the port • *%layer*: the layer of the port will be created on • *%contactdie*: the die of the port goes to

The value can also include a desired fixed string. The string that begins with %s but doesn't match the keywords will be ignored. If the value doesn't include any valid keyword, the option won't work. If %d is not specified and the new name is not unique, a underscore and uniquifying integer will be added.

`-net_naming_style` *naming_style*

Specify the naming style of new created nets. The option string contains the desired format of the new nets. The possible keywords are:

- *%s*: the original name • *%d*: integer to uniquify the net • *%layerpair*: the layers of the ports on the nets • *%diepair*: the two dies of the net connect to, the format is topdie_botdie

The value can also include a desired fixed string. The string that begins with %s but doesn't match the keywords will be ignored. If the value doesn't include any valid keyword, the option won't work. If %d is not specified and the new name is not unique, a underscore and uniquifying integer will be added.

Feedback

Description

This command creates logical connection based on bump-pair physical alignment information with top level nets. Hierarchy bumps are supported.

Examples

The following example derives the logical connection of bumps on the net VDD with I/O port.

```
prompt> propagate_3d_connections -nets VDD
```

See Also

- create_3d_mirror_bumps
- set_cell_location

---

propagate_3d_esd

Propagates the Electrostatic Discharge sources to all bumps on a 3DIC design.

Syntax

status *propagate_3d_esd*

Description

This command propagates the Electrostatic Discharge (ESD) sources in a 3DIC design. The ESD sources are propagated through the logical connectivity to all bumps based on the scope of the ESD source. Because propagation is based on the logical connectivity, the inter-die logical nets must be created prior to running this command (see *derive_3d_nets_from_bumps*).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example propagates the ESD sources in the current design.

```
prompt> propagate_3d_esd
```

See Also

- set_3d_esd_source
- report_3d_esd

Feedback

propagate_3d_matching_types

Propagates matching types of bumps, pins and tsv by tracing nets and bump contacts.

Syntax

status *propagate_3d_matching_types*

```
[-from source_chip_list]
[-to target_chip_list]
[-matching_types matching_type_list]
[-check_only]
[-force]
```

Data Types

source_chip_list	list
target_chip_list	list
matching_type_list	list

Arguments

`-from` *source_chip_list*

Specifies the source chips whose matching types are to be propagated. By default, all chip's matching types will be propagated.

`-to` *target_chip_list*

Specifies the target chips that the specified matching types will be propagated to. By default, all chips will be propagated to.

`-matching_types` *matching_type_list*

Specifies the matching types in the source chip to be propagated. By default, all matching types will be propagated.

`-check_only`

Performs a check for matching type propagation, but do not modify the design. By default, the command propagates the matching types and modifies the design.

`-force`

Assigns new matching types for all related objects. Related objects are objects in the target chip that have connections to the specified matching types in the source chip.

The *-force* option treats all related objects in the target chip as if they don't have matching types.

Feedback

Description

This command propagates matching types for bumps, pins and tsv by tracing nets and bump contacts. The matching type specifies which bump cells are to be connected to which I/O driver pins. The *create_matching_type* command defines a matching type constraint, and the *assign_3d_interchip_nets* command uses matching types of cells and terminals to do net assignment. This command propagates matching types of cells, pins and terminals to other pins by tracing nets and contacted bumps. Normally, two bumps that are center-aligned, are treated as "contacted" bumps. Moreover, if you set the application option *plan.3dic.bump_alignment_threshold*, two bumps with centers that are less than this value are considered to be "contacted". Note that the new matching types are assigned to the pins of objects.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

In the following example, "P1" in chip1 and "SOC/BUMP7" in chip2 have been set matching types "PG" and "SIGNAL". The *-force* option lets "PG" override the "SIGNAL" matching type.

```
prompt> propagate_3d_matching_types -from chip1 -to chip2 -matching_types
 {PG} -force
Information: propagate matching type { 'PG' } from chip chip1 to target
 chip chip2.
```

In the following example, matching types "SIGNAL" and "PG" have been set to "SIIP/P1" and "i_bump_1" in chip1, these two matching types will propagate to the pins of "SIIP/P2" and "i_bump_2" in chip2. "default" means no matching type has not been set. Because *-matching_types* is not used, both "PG" and "SIGNAL" matching types will be propagated.

```
prompt> propagate_3d_matching_types -from chip1 -to chip2
Information: propagate matching type { 'SIGNAL' } from chip chip1 to
 target chip chip2.
Information: propagate matching type { 'PG' } from chip chip1 to target
 chip chip2.
```

See Also

- assign_3d_interchip_nets
- create_matching_type
- report_matching_types

Feedback

propagate_pin_mask_constraint

Propagates the multiple-patterning mask constraint from one pin to its abutted pin on the same layer that does not have the multiple-patterning mask constraint.

Syntax

status *propagate_pin_mask_constraint*

Arguments

This command has no arguments.

Description

This command propagates the multiple-patterning mask constraint from one pin to its abutted pin on the same layer that does not have multiple-patterning mask constraint.

The abutted pins can be either two block pins or a block pin and a hard macro pin. If one of the pins is a hard macro pin, it must be the pin that has the multiple-patterning mask constraint.

If neither abutted pin has a multiple-patterning mask constraint, this command does not try to set the constraint on either pin.

The *set_editability* can enable/disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled by *set_editability*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example propagates the multiple-patterning mask constraint on abutted pins.

```
prompt> propagate_pin_mask_constraint
1
```

- check_pin_placement
- set_editability

Feedback

propagate_pin_mask_to_via_metal

Syntax

```
status propagate_pin_mask_to_via_metal
[-block block]
```

Data Types

block	string or collection

Arguments

`-block` *block*

Specify the name of the block to be processed.

Description

A via consists of three layers: upper-metal enclosure, via cut, and lower-metal enclosure. When the router drops a via on a pin, the lower-metal enclosure layer of the via is the same as the pin layer.

In a double-patterning technology, each pin-shape instance has an attribute mask_constraint, which identifies the mask to which the shape belongs, such as mask_one or mask_two. Each via instance also has attributes to identify the mask to which each of its three layers belongs.

For stream-out of design data in GDSII format, if a via's lower-metal mask attribute (lower_mask_constraint) is set to no_mask, the tool can automatically propagate the mask identity from an M1 pin-shape to the M1 layer of the via above the pin, overriding the no_mask attribute setting. To do this, use the '-propagate_pin_mask_to_via_metal' option of the write_gds command.

Some applications need the mask identity propagated to the via M1 layers to be reflected in the database. This command can be used for that purpose.

By default, this command operates on the current design. After the command is run, the M1 layer of each via instance is annotated to indicate the same mask information as the M1 pin-shape object under the via. To preserve the modified design data, save the design with the save_block command.

To operate on a design other than the current design, use the -block option.

Feedback

Examples

The following command modifies the vias in the current block by updating the lower_mask_constraint with the mask_constraint attribute of the pin-shape on which the via is incident:

```
prompt> propagate_pin_mask_to_via_metal
1
```

The following command modifies the vias in the block 'blockB' by updating the lower_mask_constraint with the mask_constraint attribute of the pin-shape on which the via is incident:

```
prompt> propagate_pin_mask_to_via_metal -block blockB
1
```

---

propagate_switching_activity

Forces the propagation of power-switching activity information.

Syntax

status *propagate_switching_activity*

```
[-scenarios scenario_list]
[-modes mode_list]
[-corners corner_list]
```

Data Types

scenario_list	list
mode_list	list
corner_list	list

Arguments

`-scenarios` *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through *-modes* and *-corners* options. Activity propagation is done separately for each scenario. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, propagation is done for the current scenario in the design.

Feedback

`-modes` *`mode_list`*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering on modes will occur.

`-corners` *`corner_list`*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering on corners will occur.

Description

Use this command to force propagation of the power switching activity information.

During the propagation of the switching activity, the information annotated using the read_saif, set_switching_activity commands is used to estimate the activity on unannotated nets. All commands that need switching activity information on all design objects use the switching activity propagation mechanism automatically.

The mechanism to propagate switching activity uses the static probability and toggle rate information you annotate to estimate the static probability and toggle rate information on unannotated design objects. The mechanism used by the tool is based on a stochastic simulation method, which is that random activity based on the annotated switching activity is generated on the annotated design objects, and this activity is propagated across the design using a zero-delay simulator. This is repeated a few thousand times, depending on the effort level specified through power.propagation_effort app option.

Once propagated, activity is retained until a design changes causes the activity to be invalidated. If you wish to be informed of this, you can un-suppress the messages POW-001 and POW-051 with the *unsuppress_message* command. These messages are suppressed by default.

Feedback

propagate_topology_plans

Propagates topology plans across multiply-instantiated block (MIB) instances that are in the current design.

Syntax

collection *propagate_topology_plans*

```
[topology_plan_list]
[-no_overwrite]
```

Data Types

```
topology_plan_list  collection
```

Arguments

topology_plan_list

Specifies a list of topology plans to propagate. The list can contain topology plan names, patterns, or collections. A collection can be specified by using the *get_topology_plans* command.

`-no_overwrite`

Do not overwrite any existing topology plans

Description

The *propagate_topology_plans* command propagates topology plans across MIB instances that are in the current design. If *topology_plan_list* is specified, those topology plans are propagated. If it is not specified, then all topology plans in the current block are propagated. Upon successful propagation, this command returns a collection of topology plans created during the propagation.

A topology plan is propagated if it satisfies the following conditions:

- The topology plan is associated with a bundle that consists of supernets.
- The supernets of the bundle have similar connectivity, that is, they have the drivers and loads on the same blocks. In addition, all the driver and loads blocks are MIB cells.

By propagation, the *propagate_topology_plans* command does the following:

- Find all the bundles that have the same bundle width, the same MIB driver pins, and the same MIB load pins as the bundle associated with the topology plan to be propagated from, that is, the source bundle. These are the potential bundles that the topology plan is to be propagated to.
- Check the MIB instances relative placement of the bundles obtained from the previous step and compare it to the MIB instances relative placement of the source bundle. If

Feedback

the MIB instances relative placement of the bundle is similar to the source bundle, then the topology plan is propagated to it from the source bundle. The bundle to which the topology plan is propagated to is the destination bundle.

- If the destination bundle is already assigned to the topology plan, the plan is overwritten unless the *-no_overwrite* option is specified.
- Create the topology nodes and edges for the destination bundle in the same manner as those on the source topology plan of the source bundle. If the source topology plan has net estimation rules on the plan or the edges, duplicate them on the new topology plan. If the source topology plan or its nodes or edges have any user-defined attributes, duplicate them on the new topology plan as well.

Examples

The following example propagates the current topology plan across MIB instances.

```
prompt> propagate_topology_plans [current_topology_plan]
prompt> propagate_topology_plans [current_topology_plan] -no_overwrite
prompt> propagate_topology_plans [get_topology_plans A2B]
```

- optimize_topology_plans
- report_topology_plans

---

push_down_clock_trunks

Pushes down top-level clock trunk cells. The cells are pushed into blocks which have been enabled for feedthrough creation. This command is needed only in CTP-Pushdown flavor.

Syntax

status *push_down_clock_trunks*

`[-clock clocks]`

Data Types

clocks collection

Arguments

`-clock clocks`

Specifies a list of clocks for which the clock trunk cells must be pushed down. By default, all top-level clock cells are pushed down.

Feedback

Description

During clock trunk planning, feedthroughs can be planned by creating clock buffers and physically placing them on the top of a block. Initially, clock buffers created in this way belong to the top level. When planning is complete, the top-level clock buffers must be pushed down into blocks, and feedthroughs must be created. After push down, any remaining unplaced block ports, in particular the newly created ports from the feedthroughs, must be placed.

This command pushes down the clock buffers, creates feedthroughs, and places the newly created block ports. This command is typically used at the end of an automatic or manual clock trunk planning session.

Cells are only pushed down into blocks which have been enabled for feedthrough creation with the *create_block_pin_constraint -allow_feedthroughs* command.

This command is needed only in CTP-Pushdown flavor where blocks are in readonly mode.

Examples

The following example pushes down clock cells on top of blocks for all clocks.

```
prompt> push_down_clock_trunks
```

See Also

- gui_load_clock_trunk_planning

---

push_down_objects

Pushes top-level objects into blocks.

Syntax

string *push_down_objects*

```
[-cells block_instance_collection]
object_collection
```

Data Types

```
block_instance_collection collection
object_collection         collection
```

Feedback

Arguments

`-cells` *`block_instance_collection`*

Specifies which block instances to push down objects into. By default, all blocks are processed.

`object_collection`

Specifies the object collection to be pushed down. The objects include nets, routing objects (paths, vias and terminals), routing guides, routing corridors, blockages (placement, shaping, routing), cell rows (wire tracks indirectly when rows are specified), charging stations (non-primary voltage areas and their associated single-rail repeater cells), edit groups, bump regions and grids. Note that the *get_shapes* command only returns a collection of paths; the command does not return vias. To include vias, use the *get_vias* command.

For example, if *net_collection* is included with object_collection, this command pushes down routing objects associated with the specified nets. Note that via matrix is always pushed down with its owner net. So if and only if user specify the owner net in the *net_collection*, the via matrix can be pushed down.

The *object_collection* is required for this command.

The following descriptions describe actions that the command performs on the object at the top level and block level. The actions for each object are specified by using the *set_push_down_object_options* command.

The supported objects that can be pushed down into blocks are *pg_routing*, *signal_routing*, *routing_guide*, *routing_corridor*, *blockage* (placement, shaping, routing), *pin_guide*, *pin_blockage*, *site_rows*, *cells*, *charging_station*, *edit_group*, *bump_region* and *grid*. Each object is described below.

- *pg_routing*

  The *pg_routing* objects include paths, vias and terminals that connect to power and ground nets. If a net connects to these objects at the top level, but does not exist in the block, the command creates a child net in the block. If a top-level terminal overlaps with the block and connects to a top-level power and ground net, this command copies the terminal into the block as a block pin with the same shape as the terminal. When terminals are pushed down into blocks as block terminals, they remain in the top cell. They are never removed, regardless of the top_action.

  If the net that is being pushed into a block has a connection to a block, then that port determines what net in the block that the created routing is assigned to in the block. For instance, if the net being pushed is VDD0 and connects to block A/VDD, then the routing in the block is created for net VDD in the block.

Feedback

If the net that is being pushed into a block has a nondefault routing rule (NDR), then that NDR will be created for the new net in the child block.

If the design has MIB instances and PG straps crossing MIB instances, the MIB instances are checked for correct horizontal and vertical alignment of the MIB instances. If misalignment is detected, all PG routing into blocks is suppressed. This can be overriden using the *set_push_down_object_options -object_type pg_routing -ignore_misalignment true*.

The valid top actions for routing objects are *keep* and *remove*, and the valid block actions for routing objects are *copy*, *create_pin_shape*, or both options at the same time. The default top action for *pg_routing* is *remove* and the default block action for *pg_routing* is *create_pin_shape*.

For the routing object type,

If you specify *set_push_down_object_options -top_action keep*, the top-level routing object is untouched after running *push_down_objects*.

If you specify *set_push_down_object_options -top_action remove*, the *push_down_objects* command removes the overlapping section of the top-level route object that overlapped with the block boundary. If paths are collinear with the block boundaries, the paths are not removed from the top.

If you specify *set_push_down_object_options -block_action copy*, (mutually exclusive with *create_blockage*), the *push_down_objects* command copies into the block the overlapping section of the top-level object that overlapped with the block. The newly created block-level routing object is connected to its corresponding block net. A block port and net is created if necessary.

If you specify *set_push_down_object_options -block_action create_blockage*, (mutually exclusive with *copy*), the *push_down_objects* command copies into the block as a routing blockage the overlapping section of the top-level object that overlapped with the block boundary. The newly created block-level routing blockage is not associated with any net, and the netlist is unaffected in both the top and block. The original top-level routing object is retained in the top block without regard to the *-top_action* option setting.

If you specify *set_push_down_object_options -block_action create_pin_shape*, the *push_down_objects* command creates pin shapes where the routing object touches the block boundary. However, if the *object_collection* contains only vias and nothing else, then by specifying *set_push_down_object_options -block_action create_pin_shape*, pins will be created for all vias that touches and within the block boundary. A port is created if necessary. If paths are collinear with the block boundaries, the pin

Feedback

shapes are created collinear for the length of the collinear path. All terminals created in blocks are created with fixed status.

Note that pins are created based only upon either top-level terminal overlap with a block or wire overlap with a block (normally at block boundary crossings). Pins are not created from other net-connected shapes such as rectangles (with or without "macro_pin_connect" attributes). Such shapes do get pushed down into the block, but pins are not created derived from these shapes. Also, such shapes that do get pushed into a block are cut by the amount of overlap with the block, and whatever is left in the top is replaced with rectangles with the overlapped part removed.

In the unusual case where the source of the pin creation from collinear overlap is a wire that looks like it is a horizontal wire with its end overlapping perpendicularly over a block edge, but in fact the wire is technically the other type (horizontal-looking but x endpoint are the same x value, or vertical-looking by y endpoints are the same y value), then the pins that result from this scenario will be created as if the wires really are as they appear, overlapping perpendicularly. The wire is still a collinear wire and will not be modified in the top, but the pins will be cut inside the block like a normal perpendicular overlap produces, and any wires created inside the block from the overlap will be created like normal perpendicular overlap as well.

If you specify *set_push_down_object_options -block_action {copy create_pin_shape}*, the *push_down_objects* command creates a copy of the routing object in the block and creates pin shapes where the routing objects touch the block boundaries.

If you specify *set_push_down_object_options -block_action center_pin_from_wire*, the *push_down_objects* command creates a center pin from the wire shapes (paths) passed into the command using [get_shapes]. This block action must be used with great caution, as it will create a center pin for EVERY path shape passed into the command. You must be sure you use this block_action ONLY with a limited number of explicitly specified path shapes. This block action can ONLY work with block action *create_pin_shape*.

If you specify *set_push_down_object_options -routing_overlap_check*, the *push_down_objects* command performs additional checks. If you combine the routing overlap check with *set_push_down_object_options -top_action remove* and *set_push_down_object_options -block_action copy* or *set_push_down_object_options -block_action {copy create_pin_shape}*, the *push_down_objects* command checks for overlaps between objects of the same types (wires against wires, vias against vias). If an overlap exists in the design, the command errors out without pushing down the overlapped object. Since command *push_down_objects* does limited overlap

Feedback

checking, you must use more specific DRC checks to prevent DRC violations and shorts. This checking is only done against existing real physical metal objects like wires and vias. It does not check for routing blockages. This applies to both PG routing and signal routing.

By default, when pins (terminals in blocks) are created after push-down of a signal or of PG routing, they are created as squares. The length of the created pin (the distance from the edge that touches a boundary to the opposite pin edge) is the same as the wire width (for the wire that was used to create the pin). However, the pin length can be extended to a length that is longer than the wire width under either of these two conditions: 1) A minLength rule exists for the layer of the pin (where the minLength is larger than the wire width) or 2) a length determined by the minArea rule, where the calculated length is larger than the wire width or the minLength rule.

If the minLength pin length results in the pin extending further into the block than the routing extends, this introduces the possibility of spacing/short violations with objects in the child block. For this reason, the command attempts to only create the pin from PG strap overlap by starting at the end of the strap where it extends into the block, and measuring outward enough to meet minLength/minArea requirements. This can result in the PG pin extending outside the block a small amount. But the amount that it extends should not exceed the top-level PG routing, so that should not result in pin are that is not already covered by top-level PG routing. The best way to avoid this scenario is to try to make sure that all PG straps overlap a block enough to meet minLength/minArea pin rules. And try to avoid placing objects in the block close enough to the block boundary to have spacing/short violations with the pushed-down PG pin.

For pg_routing, the *set_push_down_object_options* command supports two options to help avoid DRC violations in the block: *-collinear_margin* and *-pin_meet_fatwire_rule*. You must also include the *-object_type pg_routing* option.

The *-collinear_margin* option specifies a distance within which the closest edge of a PG route parallel to (but not overlapping) the block boundary is considered a collinear PG route. A normal collinear PG strap is one that runs parallel to an edge, but overlaps it so that one edge is inside the boundary and the other edge is outside the boundary. Normally, PG straps which run parallel, but do not overlap the boundary, are not treated as collinear straps. Collinear straps are only created in the child block as copies of the original top-level strap, and the original strap is left untouched in the top. With this option, the command will include non-overlapping PG straps and include them as copies in the child block so that their DRC effect can be observed in the block. These will appear outside of the block boundary in the child reference block.

Feedback

By default, this option is -1, and the command only considers overlapping parallel PG straps as collinear straps.

If the value of the *-collinear_margin* option is 0 (as in microns), only non-overlapping parallel straps that exactly abut a boundary edge will be pushed into the block as a collinear strap. If the value is greater than zero, any PG strap parallel to a block edge will be copied into the block as a collinear strap if the closest edge of the strap is within the distance specified in the option.

Note that this expanded margin for collinear routing only captures wires and vias that fall inside the expanded instance margin. It does not capture non-routing shapes such as rectangles and polygons, because such shapes are not considered collinear.

The *-pin_meet_fatwire_rule* Boolean option is false by default. If this option is true, the command ensures that the size of the PG pin is big enough to trigger fat-wire spacing rules within the block. To do this, the command creates a pin that is as long (in the direction perpendicular to the edge) as it is wide. This length is created inside the boundary if it can safely be done. But if the strap which was the basis for the pin only overlapped the block less than that length, then the pin can protrude outside the boundary.

The *-create_pg_feedthrough* Boolean option is false by default. If this option is true, the command will create PG feedthrough for pg terminals and cells.

If you specify *set_push_down_object_options -location_based_terminal_naming*, the location and layer information will be embedded in terminals names, the names are composed as follow:

BaseNetName + "__" + PinShapeCenter_X + "_" + PinShapeCenter_Y + "_" + LayerName

- *signal_routing*

  The *signal_routing* objects include paths, vias and terminals that connect to signal nets. Signal nets specified can be in any physical level of the physical hierarchy. If a net connects to these objects in the block in which the net resides, but does not exist in a block instance that the net overlaps, the command creates a child net in the overlapped block.

  If the net that is being pushed into a block does have a connection to a block, then that port will determine what net in the block that the created routing is assigned to in the block. For instance, if the net being pushed is FOO and connects to block A/FOO, then the routing in the block is created for net FOO in the block.

  If the net that is being pushed into a block has a nondefault routing rule (NDR), then that NDR will be created for the new net in the child block.

Feedback

The valid top actions for signal routing objects are *keep* and *remove*, and the valid block actions for routing objects are *copy*, *create_pin_shape*, or both options at the same time. The default top action for *signal_routing* is *remove* and the default block action for *signal_routing* is *create_pin_shape*.

If you specify *set_push_down_object_options -routing_overlap_check*, the *push_down_objects* command performs additional checks. If you combine the routing overlap check with *set_push_down_object_options -top_action remove* and *set_push_down_object_options -block_action copy* or *set_push_down_object_options -block_action {copy create_pin_shape}*, the *push_down_objects* command checks for overlaps between objects of the same types (wires against wires, vias against vias). If an overlap exists in the design, the command errors out without pushing down the overlapped object. Since command *push_down_objects* does limited overlap checking, you must use more specific DRC checks to prevent DRC violations and shorts. This checking is only done against existing real physical metal objects like wires and vias. It does not check for routing blockages. This applies to both PG routing and signal routing.

For the signal routing object type, if you specify *set_push_down_object_options -top_action keep*, the top-level signal routing object is untouched after running *push_down_objects*. No ports are created for the blocks into which the routing is pushed, and the routing objects in the blocks are created without connection to any net. Because no ports are created, no pins are created at the boundary if the *top_action* is *keep*. *set_push_down_object_options -block_action create_pin_shapes* should not be used in combination with *set_push_down_object_options -top_action keep*. Note that multiple push-downs of routing objects with *top_action keep* results in multiple copies of the routing created within the blocks.

If you specify *set_push_down_object_options -top_action remove*, the *push_down_objects* command removes the overlapping section of the top-level signal routing object that overlapped the block boundary. If the paths are collinear with the block boundaries, the net is skipped.

If you specify *set_push_down_object_options -block_action copy*, (mutually exclusive with *create_blockage*), the *push_down_objects* command creates a copy of the part that original top-level object overlapped with the block boundary. In addition, the newly created block-level routing object is connected to its corresponding block net. A block port and net are created if necessary.

If you specify *set_push_down_object_options -block_action create_blockage*, (mutually exclusive with *copy*), the *push_down_objects* command copies into the block as a routing blockage the overlapping section of the top-level object that overlapped with the block boundary. The newly

Feedback

created block-level routing blockage is not associated with any net, and the netlist is unaffected in both the top and block. The original top-level routing object is retained in the top block without regard to the *-top_action* option setting.

If you specify *set_push_down_object_options -block_action create_pin_shape*, the *push_down_objects* command creates pin shapes where the routing object touches the block boundary. A port is created if necessary. If you specify *set_push_down_object_options -block_action {copy create_pin_shape}*, the *push_down_objects* command creates a copy of the routing object in the block and creates pin shapes where the routing objects touch the block boundaries.

The command assesses the routing and determines whether feedthrough ports are a potential necessity. By default, feedthroughs are not created unless the command detects pin constraints for the net that indicate that the command is free to allow feedthroughs on the net. If so, and the routing requires a feedthrough port on the block, the feedthrough ports are created automatically. These feedthrough ports are automatically updated for multi-voltage (MV) boundary conditions if the design has UPF constraints.

In the default configuration for allowing feedthroughs for signal nets (false by default), the command creates an extra terminal on the block for each secondary and more crossings of the block boundary. These are essentially EEQ (electrically equivalent) pins.

If feedthroughs are allowed, and feedthrough pins are created which result from a terminal overlap with a block, the pin which is derived from that terminal will not have user attributes copied from that terminal, as it normally would if the pin were not a feedthrough pin (a pre-existing logical connection).

To control whether feedthroughs are allowed on a net, set a pin constraint by using the *set_individual_pin_constraints -net netname -allow_feedthroughs true* command. This is absolutely necessary if you intend to push down routing into a block and to create feedthroughs. If you don't allow feedthroughs by using the *set_individual_pin_constraints* command, only one port will be created for a net that crosses a block multiple times for nets with no preexisting logical connections. That port direction will be INOUT, and multiple EQ pins will be created in the block for that port. In the top level, the one port will be assigned to original top-level net that crossed the block. Such a behavior is almost always NOT intended. Ensure that you use the *set_individual_pin_constraints -net netname -allow_feedthroughs true* command if you are pushing down routing into a block that the net is not connected to logically, and you expect a feedthrough (multiple ports) to be created.

Feedback

By default, if feedthroughs are created and new "split" nets are generated as a result of the original net being broken into pieces, the command composes split net names based on the top-level net name. These split net names can be customized using the *plan.pins.new_port_name_tag* and *plan.pins.new_port_name_tag_style* application options. The plan.pins.new_split_nets_use_block_names application option also controls the naming convention.

Note that if a signal is being pushed down for feedthrough creation, and some routing terminates with connections to leaf cells that are on top of blocks that part of the routing can be pushed into, the command will refuse such a net, because the command requires that such leaf cells be included for push-down in such a scenario.

```
set_app_options -name plan.pins.new_split_nets_use_block_names
 -value true
```

If the *plan.pins.new_split_nets_use_block_names* application option is set to true, the command embeds information about the blocks that are involved in the generated split net into these split net names. The master names of these blocks is embedded into a substring of the new net name. This substring starts with the master name of the driving block, followed by a sequence of all the load blocks master names, separated by double underscore characters. This option is false by default.

The names are composed as follows:

If Suffix name tag style (default):

BaseNetName + "__" + BlockBasedSubString + "__" + NameTag + __ IndexNumber

If Prefix name tag style:

NameTag + "_" + IndexNumber + "__" + BaseNetName + "__" + BlockBasedSubString

Note that this only applies to split nets that connect one block to one or more other blocks. It WILL NOT apply to any split net that has a top port connection in the block in which the split net belongs.

Routing objects which have no net associated with them are pushed down into the block with no net association in the block. Because there is no net association, there is no need to create new ports on the block. Any remaining top-level segments of the routing object continue to have no net association.

The command creates block pins for terminals which overlap a block, even if the net has no routing. All terminals created in blocks are created

Feedback

with fixed status. When terminals are pushed down into blocks as block terminals, they remain in the top cell. They are never removed, regardless of the top_action. If a net has preexisting connections to a block and those preexisting connections have preexisting physical pins, but the routing does not touch those pins, such pins will be deleted unless they have a fixed status.

Attributes are copied from the corresponding top-cell object for all objects created in child blocks.

Wire-stubs are supported in signal routing push-down, but only supports scenarios where the routing crosses a given block instance one time. If it crosses a block, exits, and then recrosses the block (either by looping back or if the block is rectilinear in such a way that the block gets crossed more than one time), then the tool issues an error message and the net is rejected for push-down. This is because such a routing might require multiple child block nets, but for wire-stubs the tool assumes that all routing in a block belongs to one child net.

By default, when pins (terminals in blocks) are created as a result of push-down of a signal or PG routing, they are created as squares. The length of the created pin (the distance from the edge that touches a boundary to the opposite pin edge) is the same as the wire width for the wire that was used to create the pin. However, the pin length might be extended to a length that is longer than the wire width under either of these two conditions: 1) a minLength rule exists for the layer of the pin (where the minLength is larger than the wire width) or 2) a length determined by the minArea rule where the calculated length is larger than the wire width or the minLength rule.

Abutted Pin Synthesis Support

The command supports an option for validating designs with routing pushed into abutting multiply instantiated blocks (MIBs). After the command pushes down all routing and terminals, the command determines if any newly-created MIB pins abut another block edge. If the MIB pins abut a block edit, the tool examines the relationship of the abutting pin with the adjacent block and creates a corresponding pin on the adjacent block. If there is a previously existing logical connection between the new pin (which is a single pin with no abutted pin initially), the tool creates an abutting physical pin to abut the previously single pin. If no logical connection exists with the adjacent block, then either a new pin with a dangling net will be created in the adjacent block (in the event that the single pin is an output pin), or if the single pin is an input pin, then a tie-low net will be used in the adjacent block and an abutting pin will be created.

If the new pin resulting from the *push_down_objects* command on an MIB block is a feedthrough pin, and it abuts with another newly-created

Feedback

MIB feedthrough pin, then a new net will be created to stitch the two MIB feedthrough pins together.

This feature can be activated by setting the *plan.pins.synthesize_abutted_pins* application option to true.

Note that abutted pin synthesis only supports pin propagation for connections created as a result of feedthrough push-down, which will result in a single physical pin per logical connection. Multiple physical pins for the particular block port are not supported in abutted pin synthesis. Such pins are referred to as EEQ (Electrically Equivalent) pins, and these normally result from pushing down PG routing which cross the block boundary at multiple locations, but which only uses one block port for all the crossings.

- *routing_guide* and *blockage*

  If the *routing_guide* or *blockage* (placement, shaping, routing) objects are included in *object_collection*, and the routing guides or blockages overlap the block boundaries, the overlapping section of the top-level object is pushed down into the block. New routing guides or blockages are created based on the nonoverlapping sections and the tool removes the original top routing guides or blockages.

  The valid actions for routing guides and blockages (placement, shaping, routing) are:

  ```
  set_push_down_object_options -top_action keep
  set_push_down_object_options -top_action remove
  set_push_down_object_options -block_action copy
  ```

  The default actions for the routing guide and blockage objects are:

  ```
  set_push_down_object_options -top_action remove
  set_push_down_object_options -block_action copy
  ```

  If *set_push_down_object_options -top_action remove* and *set_push_down_object_options -block_action copy* are specified, the tool pushes the overlapping section of the routing guides or blockages down into the block. The top original routing guides and blockages are removed and new routing guides and blockages are created based on the nonoverlapping sections.

  If *set_push_down_object_options -top_action keep* and *set_push_down_object_options -block_action copy* are specified, the overlapping sections are copied into the block and the original top-level physical objects are untouched.

- *pin_guide* and *pin_blockage*

Feedback

If the *pin_guide* or *pin_blockage* objects are included in *object_collection*, and the pin guides or pin blockages overlap the block boundaries, and the associated pin guide or pin blockages objects have connections to the block, and the block is the parent of the pin guide, the whole pin guide or pin blockage is pushed down into the block. New pin guides or pin blockages are created based on the boundaries of the original top pin guides or pin blockages.

For pin blockages specifically, the blockage will be pushed into the overlapped block if the blockage has NO associations at all. If, the blockage does have associations, but not to the current overlapped block, then it is not pushed into the block. So in effect, NO ASSOCIATIONS is equivalent to association with all blocks.

The valid actions for pin guides and pin blockages are:

```
set_push_down_object_options -top_action keep
set_push_down_object_options -top_action remove
set_push_down_object_options -block_action copy
```

The default actions for the pin guide and pin blockage are:

```
set_push_down_object_options -top_action keep
set_push_down_object_options -block_action copy
```

If *set_push_down_object_options -top_action remove* and *set_push_down_object_options -block_action copy* are specified, the pin guides or pin blockages are pushed down into the block and the top original pin guide and pin blockage are removed.

If *set_push_down_object_options -top_action keep* and *set_push_down_object_options -block_action copy* are specified, the pin guides or pin blockages are copied into the block and the original top-level physical objects are untouched.

- *site_rows*

  If standalone *site rows* (those not part of a site array) are included in the *object_collection*, those standalone site rows that overlap block boundaries are copied into the block. Along with the site rows, wire tracks are automatically pushed down when site rows are pushed down. All wire tracks over the blocks are pushed down. If there are standalone site rows being pushed into the block, the preexisting site rows are erased and site rows are created.

  If there are wire tracks being pushed into the block, all preexisting wire tracks with the "copied_down" shadow status in the block are erased and new wire

Feedback

tracks are created. Wire tracks are not removed from the top block during this site row and wire track push-down.

Note that if MIB block instances are present and are misaligned, then this will be detected by the command. If all block instances are considered for push-down (the default... meaning the -cells option is not used) then site rows will not be pushed into any blocks. This can be worked around by either setting the *-ignore_misalignment* option in *set_push_down_object_options* to true:

Or, you can push down into specific non-MIB instances using the *-cells* option. For non-MIB instances, the use of *-cells* will disregard any MIB misalignment.

Or just fix the MIB misalignment issue and run site row push-down again.

The are no top or block actions for site rows.

- *site_arrays*

  If *site arrays* are included in the *object_collection*, site arrays that overlap block boundaries are copied into the block. Along with the site arrays, wire tracks which are non-derived (they don't belong to any site array in the parent block) are automatically pushed down when site arrays are pushed down. All non-derived wire tracks over the blocks are pushed down. If there are preexisting wire tracks in the block, the preexisting non-derived wire tracks with the copied-down shadow status or site arrays of the same name are erased and new wire tracks and site arrays are created. Wire tracks are not removed from the top site during this site array and wire track push-down. The exception to this rule is that if wire tracks exist in the top block that belong to a site array that is pushed down, then some, or all of such site-array-owned tracks will be removed from the top. If a default site array is specified for push-down into a block, any existing default site array (along with any preexisting non-site-array standalone site rows) in the block is deleted before push-down, and replaced with the new pushed-down default site array. Default site arrays are never removed from the top after push-down. Nondefault site arrays are removed automatically from the top block if the site array boundary is completely enclosed within the block instance boundary, but kept otherwise.

  Note that if user-created wire tracks exist in a block that a site array is pushed into, these will not automatically be deleted during wire track push-down associated with site-array push-down. The command will ONLY pre-delete wire tracks which have the "copied_down" shadow status.

  There are no top or block actions for site arrays.

- *cells*

Feedback

If *cells* are included in the *object_collection*, cell instances that overlap block boundaries are copied into the block that is overlapped. Cells specified for push-down can reside in any physical level of the top-design's physical hierarchy. When multiple cells are pushed down, any nets that connect to only these cells are automatically pushed down into the block also. Any routing associated with these internal nets is automatically pushed down also. The same is true for any cells that have a preexisting connection to the block, and that net does not connect to any other cell besides one (or more) being pushed down. This is a mandatory action because the top-level net is removed from the top-level cell. This action is not controlled by any option which can be set with the *set_push_down_object_options* command.

If the cells being pushed into the specified block are connected to PG nets, then the command will connect the cells in the block to the child-level PG nets that are connected to the block in the top. If, for some reason, these PG nets are not connected to the block in the top, the command will create new PG ports and nets and connect the cells in the block to these new ports/nets. The ports and nets will have a name appendage added to the name of the PG nets in the top. For example, VSS in the top will be created in the block as VSS__PUSHDOWN.

By default, a block port becomes obsolete if all cells connected to the that port have been pushed into the block. The command deletes the obsolete port and issues an informational message (limited to 10 by default) when removing the port. To force the tool to retain obsolete ports, specify the block_action retain_obsolete_ports, by using the *set_push_down_object_options* command. If this option is specified, the command will retain these ports as floating ports on the block.

If multiply instantiated block (MIB) instances exist and cells are specified for push-down into more than one of these instances, the command will push down cells into each instance separately, if the cells are at different locations over the block relative to the block's origin.

The command has special support for cells which identically overlap different MIB instances. This means that each instance has the same pattern of cell overlap, (such as a chain of repeaters where each chain is overlapping each instance identically and each cell in the chain is the exact same type as a counterpart cell in a chain overlapping another MIB instance). When this is detected by the command, the command pushes the chain into one of the instances, and then essentially reuses that chain for the other instances, and just connects the new port instances for the other MIB instances.

If a cell being pushed down overlaps more than one block (if the *-blocks* option is used, then if more than one of the specified blocks), then the command reports the partial overlap with all of the blocks that the cell

Feedback

overlaps, and it chooses a block to push down into based upon which block has the most area overlap with the push-down cell. If the area of overlap with multiple blocks is equal for multiple blocks, then the command chooses the block whose boundary contains the push-down cell's origin (assuming the origin lies on top of a pushable block). If the push-down cell's origin is not within the boundary of a pushable block instance, then the command chooses the block whose origin is closest to the cell's origin.

The valid actions for cells are *set_push_down_object_options -top_action remove* and *set_push_down_object_options -top_action keep* (for physical-only cell pushdown ONLY) and *set_push_down_object_options -block_action copy* | *create_blockage*.

If you specify *set_push_down_object_options -block_action copy*, (mutually exclusive with *create_blockage*), the command *push_down_objects* creates a copy of the top-level cell instance in the block. Block ports and nets are created if necessary.

If you specify *set_push_down_object_options -block_action create_blockage*, (mutually exclusive with *copy*), the *push_down_objects* creates a placement blockage in the block. The netlist is unaffected in both the top and block. The original top-level cell instance is retained in the top block without regard to the -top_action option setting.

If you specify *set_push_down_object_options -object_type cells -allow_multi_rail_cells true*, (only allowed in combination with the *cells* object type), the *push_down_objects* will allow the push-down of MV type cells with multi-rails and no UPF strategy. Without this object-type-specific option, the command will issue an error message and prevent the push-down of cells of this type.

If you specify *set_push_down_object_options -object_type cells -top_action keep*, the command will ONLY push-down physical-only cells, and disregard all other cell type during that push-down session. The physical-only cells created in the blocks will be created with the "copied-down" shadow status, and no nets or ports will be created in the block. The physical-only cells in the top will be untouched.

If you specify *-create_pg_feedthrough* the command will create PG feedthrough for pg terminals and cells.

- *routing_corridor*

  If *routing corridors* are included in the *object_collection*, routing corridors that overlap block boundaries are copied into the block. All nets which are associated with the top-block routing corridor being pushed down are searched for in the block and if a block-level net is found to be connected to the top-level net, then the block-level counterpart gets associated with the

Feedback

new routing corridor in the block. If no block-level nets can be found in the block which map to those in the parent block (by port connection), then the routing corridor in the block will still be created, but with no net associations. If a routing corridor exists in the block with the same name as the one being copied down, and it possesses the copied-down shadow status, it is removed and replaced with the one being copied down.

- *charging_station*

  If *charging_stations* (also referred to as gas stations, which are non-primary voltage areas in MV designs which have associated single-rail repeater cells) are included in the *object_collection*, the command examines the regions of the top-level charging station, and the cells it owns, and determines if the command can legally propagate the voltage area and its cells to the deepest block (in terms of physical hierarchy depth) that the voltage area overlaps. The voltage area must completely fit into that block, and that block must already have UPF supply nets that are equivalent to those associated with the charging station in the top. If the command concludes that it can successfully accommodate the UPF requirements, and the cells are found to be only single-rail repeater buffers or inverters, then the command will create a new charging station in the target block (the deepest overlapped block) and then push the repeater cells down a physical level at a time, propagating all signal ports and nets as it pushes the repeater cells down to the destination target block. It then associates the new cells with the new voltage area and applies all necessary UPF connections and constraints to the new cells and all new ports created on the way down.

  The new charging station will receive all user attributes that existed on the top-level charging station (Voltage Area) and the new repeater cells will also receive copies of user attributes from the top-level repeater cells.

  The charging station is removed from the top if all of its regions were pushed down into the destination block. If only some of the charging station's regions were pushed down, then only those regions are removed from the top block.

  All new charging stations and associated repeater cells are given the appropriate shadow status (pushed-down or copied-down).

  The only valid top action for charging_station objects is *remove*, and the only valid block action for charging_station objects is *copy*. These are also the default top and block actions for *charging_station* objects.

- *edit_group*

  If *edit groups* are included in the *object_collection*, and the edit groups are fully covered by block boundaries, all members of the edit groups and themselves are pushed into the blocks with the orignal value of attribute is_locked. Meanwhile, a suffix "__PUSHDOWN" will be added to the newly

Feedback

created edit groups, and all members are pushed down in their respective ways as mentioned above.

Push down only support PG routings(except terminals), cells, routing blockages, placement blockages, shaping blockages, pin blockages, routing guides, pin guides as edit group members. If an edit group contains other types of objects, it won't be pushed down. Nested edit group is not supported. The only supported top action is *remove*, block action is *copy*.

In MPH scenario, if an edit group contains pin guide/blockage, it can only be pushed into 1st child level. If an edit group fully overlaps the cell boundary in level-1, and partially overlaps the cell boundary in level-2, it will be pushed down into level-1, and stay in level-1 as a complete edit group.

- *bump_region*

  If *bump_regions* are included in the *object_collection*, the region will be cut by its overlapping block boundaries, and the boundary, pattern offset, orientation, pitches, and staggers of new regions will be re-calculated to make the pseudo bumps look the same from top level as before. After push down, new top regions are anchored to same anchor objects and locations, the original associated net/port matrix will be kept for the new created top regions and be mapped to connected child nets/ports for new child regions. The associated pseudo TSVs will also be mapped to new bump regions.

  The top action can be *keep*/*remove*, and block action is forced to *copy*. If top action is set to *keep*, new region will be with shadow status copied_down, otherwise the attribute is set to pushed_down.

  If multiple to-be-created regions would overlap each other and have different attributes, they won’t be pushed down, and a warning message will be reported.

- *grid*

  If *grids* are included in the *object_collection*, they will be copied into specified child blocks.

Description

This command transfers objects from the top level to the block level. It will continue pushing down objects to the deepest physical depth as controlled by the command *set_editability* .

The *set_editability* command can enable or disable the *push_down_objects* command for blocks or levels of physical hierarchy. The *push_down_objects* command has no effect on the blocks that are disabled by *set_editability*. It will refrain from pushing further into a block if that block has been marked disabled.

Feedback

By default, the name marker suffix "__PUSHDOWN" is appended to new cells, ports, and nets created by this command after push-down of routing and cells. You can override this name marker by using the *plan.pins.new_port_name_tag* and/or *plan.pins.new_cell_name_tag* application options as follows:

```
set_app_options -name plan.pins.new_cell_name_tag -value "MYLABEL"
set_app_options -name plan.pins.new_port_name_tag -value "MYTAG"
```

By default, the tool appends the name marker at the end port or net name. Use the *plan.pins.new_port_name_tag_style* application option to put the name marker at the front of the port name as a prefix.

```
set_app_options -name plan.pins.new_port_name_tag_style -value "prefix"
```

Note that this command invokes some setup commands, such as linking blocks and initializing UPF, before it begins to push down objects. For large designs, this can take from a second to minutes. For this reason, it is advisable to run this command on multiple nets instead of one net at a time.

Note that if buses are to be pushed down into blocks as feedthroughs, it is important that all nets of the bus are pushed down in the same call to the *push_down_objects* command, so that the feedthrough ports can be correctly defined as bus ports on the blocks that the bus feeds through. If a net of a bus is pushed down on bit at a time, bus port creation will not be correctly defined for the feedthroughs resulting from bus net push-down.

Examples

The following example pushes down the routing objects of power and ground nets.

```
prompt> push_down_objects [get_nets {VDD VSS}]
```

The following example pushes down the routing all paths.

```
prompt> push_down_objects [get_shapes]
```

The following example pushes down the routing all paths and vias.

```
prompt> change_selection [get_shapes]
prompt> change_selection [add_to_collection [get_selection] [get_vias]]
prompt> push_down_objects [get_selection]
```

The following example pushes down all placement blockages.

```
prompt> push_down_objects [get_placement_blockages]
```

The following example pushes down all routing blockages.

```
prompt> push_down_objects [get_routing_blockages]
```

The following example pushes down all routing guides into block A.

```
prompt> push_down_objects [get_routing_guides] -blocks [get_cells A]
```

Feedback

The following example pushes down the buffer BUF1 into block A

```
prompt> push_down_objects [get_cells BUF1] -blocks [get_cells A]
```

The following example pushes down all standalone site rows.

```
prompt> push_down_objects [get_site_rows -filter "is_derived==false"]
```

The following example pushes down all site arrays.

```
prompt> push_down_objects [get_site_arrays]
```

The following example pushes down all site routing corridors.

```
prompt> push_down_objects [get_routing_corridors]
```

The following example pushes down a charging station (or gas station), and all repeater cells belonging to that voltage area that overlap blocks.

```
prompt> push_down_objects [get_voltage_areas cs_00]
```

The following example pushes down edit groups

```
prompt> push_down_objects [get_edit_groups]
```

The following example pushes down bump regions

```
prompt> push_down_objects [get_bump_regions]
```

The following example pushes down a grid

```
prompt> push_down_objects [get_grids grid_1]
```

---

push_rdl_routes

Moves routed redistribution layer (RDL) wires either in a specified direction or away from the specified nets.

Syntax

status *push_rdl_routes*

```
[-nets collection_of_nets | -nets_in_file nets_file]
[-objects collection_of_objects]
-layer tech_layer_name
[-mode net | neighbor]
[-direction up | down | left | right]
[-sweep_range sweep_range]
[-bounding_box { {llx lly} {urx ury} }]
```

Data Types

collection_of_nets	collection
nets_file	string
tech_layer_name	string
sweep_range	integer
llx	float
lly	float
urx	float
ury	float
collection_of_objects	collection

Arguments

`-nets` *collection_of_nets*

Specifies the RDL nets to be pushed when using the *-mode net* option. For the *-mode neighbor* option, the *-nets* option specifies the net to push routed wires away from.

Feedback

`-nets_in_file` *`file_name`*

Specifies the name of the file that contains the RDL nets to be pushed when using the *-mode net* option.

The *-nets_in_file* and *-mode neighbor* options are mutually exclusive.

-nets has higher priority than *-nets_in_file*.

`-objects` *`collection_of_objects`*

Specifies the RDL nets (see *-nets*) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If the app option *flip_chip.route.routing_style* is *spanning_tree*, the whole nets of the cells or pins are regarded as involved.

You must specify one of these options: *-nets*, *-nets_in_file*, or *-objects*.

`-layer` *`tech_layer_name`*

Specifies the metal layer on which to push the specified RDL wires. You can specify only one metal layer. Specify the metal layer by using its technology file layer name.

This option is required.

`-mode net | neighbor`

Specify the mode used to move RDL nets. If you do not specify this option the command uses *-mode net* by default.

In the net push mode, the command pushes the RDL nets in the direction specified by the *-direction* option. A wire is pushed until it is totally blocked by a routing obstruction (a metal blockage or wire) or it meets the bounding box of the target routed net. When a wire is blocked, the tool splits the wire and tries to push parts of the wire. For example, assume that a vertical wire A is being pushed to the right, as shown in Figure 1, but blockage B partially blocks the path. When the tool finishes pushing the wire, wire A is split into 3 parts: vertical segment A1, horizontal segment C, and vertical segment A2, as shown in Figure 2.

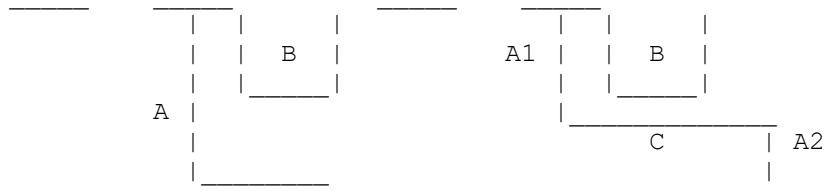

Figure 1

Figure 2

When pushing wires, the tool respects the spacing requirements defined by the *set_app_options {flip_chip.route.layer_bump_spacings list}* command.

In the neighbor push mode, the command pushes the nearest 2xN nets away from a specific net, where N is specified by the *-sweep_range N* option. You can specify only one net at a time.

`-direction up | down | left | right`

Specifies the direction in which to push the RDL nets.

This option must always be used with the *-mode net* option but never with the *-mode neighbor* option. If you do not specify the direction together with the *-mode net* option, the tool does not push any wires.

`-sweep_range` *`sweep_range`*

Specifies the sweep range value used together with the *-mode neighbor* option. The range should be from 1 to 40. Values outside the expected range result in an error. The default is 10.

`-bounding_box` *`{ {llx lly} {urx ury} }`*

Specifies a window within which to limit the push operation. For example, assume that you push net A up and you specify a window W as shown in Figure 3. After the push operation, net A is pushed but is kept within window W, as shown in Figure 4.

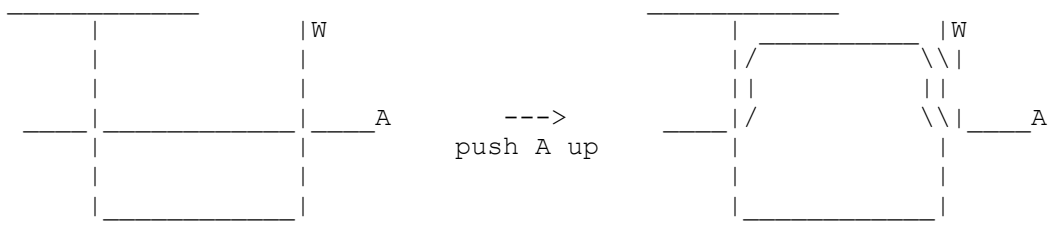

Figure 3 Figure 4

You must also specify the *-mode net* option when you specify the *-bounding_box* option.

The unit for this option is microns.

Description

This command moves routed RDL wires and supports several types of push operations.

When you push an RDL wire by using the *push_rdl_routes* command, the tool moves the wire in the specified direction until the wire is blocked by an obstacle. The command respects the spacing requirements defined by the *create_routing_rule -spacings*

Feedback

command. The RDL wires remain on their original metal layer and the connectivity is not changed.

RDL nets are nets in flip-chip designs or 3DIC designs which are routed on the redistribution layer. In a flip-chip design, RDL nets connect a bump cell to driver I/O cells. In a 3DIC or interposer design, RDL nets can connect the following elements:

- A micro-bump cell and a micro-bump cell
- A micro-bump cell and a TSV (through silicon via) cell
- A micro-bump cell and driver I/O cell

Micro-bump cells are also called flip-chip pads.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following command pushes the NET1 and NET2 rdl nets on the METAL7 metal layer in the upward direction.

```
prompt> push_rdl_routes -layer METAL7 -mode net \\
   -nets {NET1 NET2} -direction up
```

The following command pushes 40 neighboring nets (20 on each side) away from the NET3 RDL net on the METAL9 layer.

```
prompt> push_rdl_routes -layer METAL9 -mode neighbor \\
   -nets NET3 -sweep_range 20
```

---

py_eval

Evaluate python code. This is an optional feature, not all applications support Python.

Feedback

Syntax

string *py_eval* -file *<path>*

[-verbose] [-locals *dict*] *code*

```
string <path>
string code
string  dict
```

Arguments

`-file <path>`

Evaluate python code in the specified file. This option cannot be specified with code.

`-locals dict`

Use the supplied dictionary value as the Python locals value. When specified the Python code evaluates as if it is an unnamed function definition. When this option is specified you must use the Python "global" keyword to indicate that a variable name refers to a global, rather than a local variable. This option allows you to "pass" data from Tcl into your Python script directly.

code

Evaluate python statements embed within a Tcl script. This option cannot be specified with -file.

`-verbose`

Echo commands and display results during evaluation. This option is only legal when combined with -file.

Description

This command evaluates Python code in the application. The Python language uses the "snps" module to control tool behavior. That module is implicitly imported into the Python global name space.

When this command is run from within Python (i.e. cmd.py_eval(...)) the specified code (or file) is evaluated in the current module namespace. When evaluated from Tcl the code is evaluated in global namesspace.

Feedback

The Python snps module

Synopsys applications add a module called "snps" into the embedded Python interpreter. The snps module defines classes an objects that are used to interact with application builtin commands. Please see the following man pages for more details:

snps.cmd

Python object that provides access to application commands.

snps.collection

Python class that provides access to Synopsys collection values.

snps.value

Python class that provides access to application command return values.

snps.redirct

Python class used to redirect application output.

The Python interactive console

When the app_var sh_language is set to "python", the interactive language of the application is Python instead of Tcl. In this mode all input must be a valid Python expression or statement. When the input language is Python, the prompt will include "-py" to indicate this. The following example shows how to change the input language from Tcl, into Python, and then back again. Notice the changes to the prompt display:

```
fc_shell> set_app_var sh_language python
fc_shell-py> cmd.set_app_var('sh_language', 'tcl')
fc_shell>
```

The interactive Python console has a few extensions compared to the plain Python interpreter:

history()

This command prints the interactive command history and is an alias for the cmd.history() command. The tool keeps a separate history for interactive Python and Tcl. In Python mode you may evaluate commands from the history using the traditional "!" syntax.

source(fileName)

This command is an alias for the cmd.py_eval(file=fileName) command.

Examples

Evaluate the Python file in the global namespace.

```
prompt> py_eval -file pyFile.py
```

Feedback

Find pyfile.py in the Python sys.path. Creates a new module (and namespace). If code in pyFile.py depends on features of the snps module, those must be imported manually into the module namespace.

```
prompt> py_eval {import pyFile.py}
```

The return value of the py_eval can be set by assigning to the cmd.result property. In the following example the Tcl variable "x" holds the value "10".

```
prompt> set x [py_eval {cmd.result = 10}]
```

q

query_cell_instances

Finds all instances of a given library cell or module within the active scope. This is a UPF query command.

Syntax

list *query_cell_instances*

```
cell_name
[-domain domain_name]
```

Data Types

```
cell_name           string
domain_name         string
```

Arguments

cell_name

Specifies the name of the library cell or module to find in the active scope. The command reports all instances of the specified cell or module.

-domain *domain_name*

Limits the search to the instances in the specified power domain.

Feedback

Description

The *query_cell_instances* command finds all instances of a mapped cell within the active scope. It returns a list of the found instances.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports all instances of the AND2 library cell in the I_REG_FILE/PD_ALU power domain.

```
prompt> query_cell_instances -domain I_REG_FILE/PD_ALU AND2
I_ALU/C132 I_ALU/C133 I_ALU/C134 I_ALU/C135 I_ALU/C136
```

See Also

- get_cells
- query_cell_mapped

---

query_cell_mapped

Identifies the library cell or module mapped to a given instance. This is a UPF query command.

Syntax

string *query_cell_mapped*

```
        instance_name
```

Data Types

```
instance_name          string
```

Arguments

instance_name

Specifies the name of the instance to query.

Feedback

Description

The *query_cell_mapped* command identifies the library cell or module that is mapped to a given instance. It returns the cell name.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports the library cell mapped to instance I_ALU/C132.

```
prompt> query_cell_mapped I_ALU/C132
AND2
```

See Also

- get_cells
- query_cell_instances

---

query_map_power_switch

Returns information about the previous mapping of a library cell to a power switch in the active scope. This is a UPF query command.

Syntax

```
list query_map_power_switch
switch_name
[-detailed]
```

Data Types

switch_name	string

Arguments

switch_name

Specifies the name of the power switch. The command returns the full *map_power_switch* command previously used to map a library cell to the power switch.

-detailed

Returns the *map_power_switch* command information in the form of a Tcl list of keyword and value pairs.

Feedback

Description

The *query_map_power_switch* command returns the full *map_power_switch* command previously used to map library cells to a specified power switch. The *-detailed* option returns the same information in the form of a Tcl list of keyword and value pairs. If you specify an asterisk for the switch name, the command returns the mapping information for all power switches. It returns a warning message for each switch that is not yet mapped.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show how to report the *map_power_switch* command previously used to map a library cell to power switch SW1.

```
prompt> query_power_switch *
{SW1 SW2 }

prompt> query_map_power_switch SW1
map_power_switch SW1 -domain TOP -lib_cells {STN_SWITCH_Y2_PM }

prompt> query_map_power_switch SW1 -detailed
{switch_name SW1} {domain TOP} {lib_cells {STN_SWITCH_Y2_PM }}

prompt> query_map_power_switch SW2
Warning: Can't find map_power_switch constraint for power switch SW2.
 (UPF-299)
```

See Also

- map_power_switch
- query_power_switch

---

query_net_ports

Finds all the ports that are logically connected to a given net. This is a UPF query command.

Syntax

list *query_net_ports*

```
net_name
[-transitive true | false]
[-leaf]
```

Feedback

Data Types

net_name string

Arguments

net_name

Specifies the net. The command finds all ports connected to that net.

-transitive true | false

Specifies whether to search the only the current level of hierarchy (*false*, the default behavior) or both the current level and hierarchical descendants below the current level (*true*).

-leaf

Returns only the leaf-cell ports connected to the specified net. By default, both hierarchical and leaf-level cell ports are reported.

Description

The *query_net_ports* command returns the ports that are logically connected to the specified net. It returns a list of the port names. If no ports are connected to the specified net, it returns the null string.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports the ports connected to net I[30] at the current level of hierarchy.

```
prompt> query_net_ports I[30]
I[30] I_LAT/Inst_1[30]
```

The following example reports the ports connected to net I[30] at the current level of hierarchy and in descendants below the current level.

```
prompt> query_net_ports I[30] -transitive true
I_LAT/Inst_1_reg[30]/Q I[30] I_LAT/Inst_1[30]
```

The following example reports the ports of leaf-level cells connected to net I[30] at the current level of hierarchy and in descendants below the current level.

```
prompt> query_net_ports I[30] -transitive true -leaf
I_LAT/Inst_1_reg[30]/Q
```

Feedback

- get_nets
- get_ports
- query_port_net

---

query_objects

Searches for and displays objects in the database.

Syntax

string *query_objects*

```
[-verbose]
[-truncate elem_count]
[-class class_name]
object_spec
```

Data Types

class_name	string
elem_count	int
object_spec	list

Arguments

`-verbose`

Displays the class of each object found.

By default, the command lists only the name of each object. When you use this option, the command lists prefixes the name of each object with its class, as shown in the EXAMPLES section.

`-truncate elem_count`

Truncates the display to *elem_count* elements.

By default, the command displays up to 100 elements. To change the number of elements displayed by the command, use this option. To see all elements, set the *elem_count* value to 0.

`-class class_name`

Specifies the class used to search for objects when an element in the *object_spec* argument is not a collection. Valid classes are application-specific.

Feedback

If you do not specify this option, the command displays only those elements in the *object_spec* argument that are collections and displays an error message for any other elements, as shown in the EXAMPLES section.

object_spec

Specifies the objects to find and display. Each element in the list is either a collection or a pattern.

- When you specify a collection, the command displays the contents of the collection.
- When you specify a pattern, the command searches the database for objects of the class specified in the *-class* option. If you do not specify the *-class* option, the command issues an error message for the pattern.

Description

The *query_objects* command finds and displays objects in the application's runtime database. The command does not have a meaningful return value; it displays the objects found and returns an empty string.

To control the number of elements displayed, use the *-truncate* option. If the display is truncated, the command prints an ellipsis (...) as the last element. If the default truncation occurs, the command displays a message that shows the total number of elements that would have displayed, as shown in the EXAMPLES section.

Although the output from the *query_objects* command looks similar to the output from any command that creates a collection, the *query_objects* command always returns an empty string.

The *query_objects* command displays the output in either a Legacy format or in a Tcl compatible format. The default output format varies by tool but you can control the format yourself by setting the *query_objects_format* variable. For example, to force Tcl-compatible output use this command:

```
prompt> set_app_var query_objects_format Tcl
Tcl
```

The EXAMPLES section shows output in both the Legacy and Tcl formats.

Examples

These following examples show the basic usage of the *query_objects* command in both Legacy and Tcl format.

```
prompt> set_app_var query_objects_format Legacy
Legacy
prompt> query_objects [get_cells o*]
{"or1", "or2", "or3"}
prompt> query_objects -class cell U*
```

Feedback

```
{"U1", "U2"}
prompt> query_objects -verbose -class cell \\
?   [list U* [get_nets n1]]
{"cell:U1", "cell:U2", "net:n1"}
prompt> set_app_var query_objects_format Tcl
Tcl
prompt> query_objects [get_cells o*]
{or1 or2 or3}
pt_shell> query_objects -class cell U*
{U1 U2}
pt_shell> query_objects -verbose -class cell \\
?   [list U* [get_nets n1]]
{{cell U1} {cell U2} {net n1}}
```

When you omit the *-class* option, only those elements of the *object_spec* argument that are collections generate output. The other elements generate error messages.

```
prompt> query_objects [list U* [get_nets n1] n*]
Error: No such collection 'U*' (SEL-001)
Error: No such collection 'n*' (SEL-001)
{"n1"}
```

When the output is truncated, the command prints an the ellipsis at the end of the display. For the following example, assume the default truncation is 5 (it is actually 100).

```
prompt> query_objects [get_cells o*] -truncate 2
{"or1", "or2", ...}
prompt> query_objects [get_cells *]
{"or1", "or2", "or3", "U1", "U2", ...}
Output truncated (total objects 126)
```

---

query_pg

Queries specific data from the RHSC and TTSC databases.

Syntax

status *query_pg*

```
[-result result_name]
[-use_global_host_options use_global_host_options]
[-host_options host_option_names]
```

Data Types

```
result_name             string
use_global_host_options string/bool
host_option_names       string
```

Arguments

`-result` *result_name*

Specifies the result name. The default value is "default".

`-use_global_host_options` *use_global_host_options*

Uses CDPL laucher and the unnamed global host options. This option is exclusive with *-host_options*. It can be true|false or 1|0. The default value is "false".

`-host_options` *host_option_names*

Specifies that the given host option must be used for distributed processing. If not specified, the tool looks for the global host option and use the global host option if it has distributed processing settings. This option is exclusive with *-use_global_host_options true*

Description

This command queries specific data from the RHSC and TTSC databases and saves the query results in the EMIR database. This command is designed exclusively for fusion EMIR engine.

Feedback

Examples

The following example performs query and saves result in "myResult" in EMIR database:

```
prompt> set_app_options -name 3dic.emir.engine -value "fusion"
prompt> query_pg -result myResult
```

---

query_pg_extension

Check PG wire shapes meet the requirement that wire shape has desired extension against siterow.

Syntax

status *query_pg_extension*

```
[-net netname_list]
[-layer layer_name]
[-extension_value value]
```

Data Types

```
netname_list   list
layer_name     string
value          float
```

Arguments

`-net netname_list`

Specifies the name of power or ground nets for wire shape checking. This option combines with *layer* to filter desired shapes. This is a required option.

`-layer layer_name`

Specifies the name of layer for wire shape checking. This option combines with *net* to filter desired shapes. This is a required option.

`-extension_value value`

Specifies a specific value for checking the distance between wire end and siterow

Feedback

Description

This command checks the distance between wire ends and siterow. If the distance doesn't equal to *extension_value*, it will return the name of the shape.

Examples

The following example performs checking PG wire extension to siterow.

```
prompt> query_pg_extension \\
    -net VDD
    -layer M1
    -extension_value 0.2
```

---

query_port_net

Finds the net that is logically connected to a specified port. This is a UPF query command.

Syntax

string *query_port_net*

```
port_name
[-conn low | high]
```

Data Types

```
port_name                  string
```

Arguments

port_name

Specifies the name of the port to query for its connected net.

`-conn low | high`

Specifies whether to return the higher-level net (*high*, the default behavior), or lower-level net (*low*) connected to the port. For a top-level port, you must use *-conn low*, or else nothing is returned. For a port of a leaf-level cell, using this option is not allowed.

Description

The *query_port_net* command returns the net that is logically connected to the specified port. For a hierarchical port, the command returns the higher-level net by default. To return the lower-level net instead, use the *-conn low* option.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports the higher-level net connected to port I_LAT/Inst_1[30].

```
prompt> query_port_net I_LAT/Inst_1[30]
I[30]
```

The following example reports the lower-level net connected to port I_LAT/Inst_1[30].

```
prompt> query_port_net I_LAT/Inst_1[30] -conn low
I_LAT/Inst_1[30]
```

The following example demonstrates the reporting of a net connected to a top-level port, A_IN. Because the command reports the higher-level net by default, you must use the *-conn low* option to get the lower-level net name.

```
prompt> query_port_net A_IN
prompt>
prompt> query_port_net A_IN -conn low
netA_IN
```

See Also

- get_nets
- get_ports
- query_net_ports

---

query_port_state

Returns information about the port states that have been previously defined for a specified supply port in the active scope. This is a UPF query command.

Syntax

```
list query_port_state
port_name
[-state state_name]
[-detailed]
```

Data Types

```
port_name           string
state_name          string
```

Feedback

Arguments

port_name

Specifies the supply port. The command reports the port states previously defined for this port.

-state *state_name*

Returns the *add_port_state* command that was used to create the specified state. If you omit this option, the command returns a list of all the defined states for the port.

-detailed

Causes the *-state* option to return the *add_port_state* command information in the form of a Tcl list of keyword and value pairs.

Description

The *query_port_state* command returns information about the port states that have been previously defined for a specified supply port. If you specify only the port name without any other options, the command returns a list of the defined port states. If you use the *-state state_name* option, the command returns the full *add_port_state* command previously used to create that state for the port. The *-detailed* option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show how to report the port states defined for the supply port named "I_REG/I_REG_sw/out".

```
prompt> query_port_state I_REG/I_REG_sw/out
{BLOCK BLOCK_off }

prompt> query_port_state I_REG/I_REG_sw/out -state BLOCK
add_port_state I_REG/I_REG_sw/out -state {BLOCK {1.080000 }}

prompt> query_port_state I_REG/I_REG_sw/out -state BLOCK -detailed
{port_name I_REG/I_REG_sw/out} {state_name BLOCK } {state {1.080000 }}

prompt> query_port_state I_REG/I_REG_sw/out -state *
add_port_state I_REG/I_REG_sw/out -state {BLOCK {1.080000 }}
add_port_state I_REG/I_REG_sw/out -state {BLOCK_off {off }}
```

Feedback

See Also

- add_port_state
- create_supply_port

---

query_power_switch

Returns information about a power switch that was previously created in the active scope. This is a UPF query command.

Syntax

```
list query_power_switch
switch_name
[-detailed]
```

Data Types

```
switch_name        string
```

Arguments

switch_name

Specifies the name of the power switch. The command returns the full *create_power_switch* command previously used to create the power switch. Use an asterisk (*) to get a list of all the power switch names.

-detailed

Returns the *create_power_switch* command information in the form of a Tcl list of keyword and value pairs.

Description

The *query_power_switch* command returns information about previously defined power switches. The command "*query_power_switch* *" returns a list of the power switch names. If you specify the name of the particular power switch, the command returns the full *create_power_switch* command previously used to create that power switch. The *-detailed* option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following examples show how to report the *add_pst_state* command previously used to create power state s2 in power state table PST1.

```
prompt> query_power_switch *
{SW1 SW2 }

prompt> query_power_switch SW1
create_power_switch SW1 -domain TOP -output_supply_port {out SN2}
-input_supply_port {in SN1} -control_port {ctrl on} -on_state
{state1 in {ctrl}}

prompt> query_power_switch SW1 -detailed
{switch_name sw1} {domain TOP} {output_supply_port {out SN2}}
{input_supply_port {in SN1}} {control_port {ctrl on}} {on_state
{state1 in {ctrl}}}
```

See Also

- create_power_switch
- query_map_power_switch

---

query_pst

Returns information about the power state tables that have been previously created in the active scope. This is a UPF query command.

Syntax

```
list query_pst
table_name
[-detailed]
```

Data Types

```
table_name          string
```

Arguments

table_name

Specifies the name of the power state table. The command returns the full *create_pst* command previously used to create the power state table. Use an asterisk (*) to get a list of all power state table names.

-detailed

Returns the *create_pst* command information in the form of a Tcl list of keyword and value pairs.

Feedback

Description

The *query_pst* command returns information about previously defined power state tables in the active scope. The command "*query_pst* *" returns a list of the power state table names. If you specify the name of the particular power state table, the command returns the full *create_pst* command previously used to create that power state table. The *-detailed* option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show how to report the *create_pst* command previously used to create power state table PST1.

```
prompt> query_pst *
{PST1 PST2 }

prompt> query_pst PST1
create_pst PST1 -supplies {SP1 SP2 SP3 }

prompt> query_pst PST1 -detailed
{table_name PST1} {supplies {SP1 SP2 SP3 }}
```

See Also

- create_pst
- query_pst_state

---

query_pst_state

Returns information about a state in a power state table that was previously created in the active scope. This is a UPF query command.

Syntax

```
list query_pst_state
state_name
-pst_name table_name
[-detailed]
```

Feedback

Data Types

```
state_name          string
table_name          string
```

Arguments

state_name

Specifies the name of the power state. The command returns the full *add_pst_state* command previously used to create the power state. Use an asterisk (*) to get a list of all the power states for the specified power state table.

-pst *table_name*

Specifies the name of the power state table. To get a list of the power state tables in the current scope, use the "*query_pst **" command.

-detailed

Returns the *add_pst_state* command information in the form of a Tcl list of keyword and value pairs.

Description

The *query_pst_state* command returns information about the states that have been previously defined for a specified power state table. The command "*query_pst_state * -pst table_name*" returns a list of the power states defined for the specified table. If you specify the name of the particular power state, the command returns the full *add_pst_state* command previously used to create that power state. The *-detailed* option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the *source* command, but not in a script run by the *load_upf* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show how to report the *add_pst_state* command previously used to create power state s2 in power state table PST1.

```
prompt> query_pst *
{PST1 PST2}

prompt> query_pst_state * -pst PST1
{s1 s2 s3 }

prompt> query_pst_state s2 -pst PST1
add_pst_state s2 -pst PST1 -state {s12 s11 s12 }
```

Feedback

```
prompt> query_pst_state s2 PST1 -detailed
{state_name s2} {pst PST1} {state {s12 s11 s12 }}
```

See Also

- add_pst_state
- query_pst

---

query_qor_snapshot

Analyzes timing report files from existing QoR snapshots, applies any specified filters, and displays the results in an appropriate format.

Syntax

status *query_qor_snapshot*

```
-name snapshot_name
[-directory directory_name]
[-type min | max]
[-output_file file_name]
[-display]
[-sort_by column]
[-group_by column]
[-columns column_list]
[-and column_list]
[-filters filter_list]
```

Data Types

```
snapshot_name     string
directory_name    string
column            string
column_list       list of strings
filter_list       string
```

Arguments

`-name` *snapshot_name*

Specifies the name of the Query QoR snapshot result to be analyzed. This is a required option.

`-directory` *directory_name*

Specifies the name of the directory to search for the Query QoR snapshot specified by the *-name* option.

If you do not specify this option, the tool searches for the QoR snapshot in the directory specified by the application option *time.snapshot_storage_location*.

Feedback

`-type min | max`

Loads the appropriate snapshot setup report if you specify *max* and hold report if you specify *min*. This option can only be specified together with the *-name* option.

The default is *max* for loading setup.

/ / / / / /

`-output_file` *`file_name`*

Specifies the name of the generated output html file.

`-sort_by` *`column_list`*

Specifies the column used to sort the results. The default is wns.

To sort a column in descending order, specify "*column_name*" or "+*column_name*". To sort a column in ascending order, specify "-*column_name*". Two exceptions: *wns* and *zero_path* columns have their default sorting order reversed (+*wns* results in an ascending sort). This is so that the default sort order for a column produces the most meaningful sorting order (descending for most numeric columns).

Valid sort columns are: path_group, startpoint, endpoint, scenario, wns, transition_degradation, slew_degradation, zero_path, logic_levels, path_delay, input_delay, output_delay, clock_uncertainty, incremental, transition_time, capacitance, fanout, clock_skew, launch_clock, launch_clock_latency, capture_clock, capture_clock_latency, bufinvcount, io_path, and cross_clock.

`-group_by` *`column_list`*

Specifies the column used to group the results. This option groups the results based on the unique values found for this column to create a summary that links to details for that value of the column.

Valid group columns are: path_group, startpoint, endpoint, scenario, launch_clock, capture_clock, bufinvcount, logic_levels, cross_clock and io_path.

`-columns` *`column_list`*

Specifies the list of columns to include in the output. The columns are displayed in the specified order. The columns should be separated with spaces. If you specify a column multiple times, its location is determined by the last instance.

Valid columns are: path_group, startpoint, endpoint, scenario, wns, transition_degradation, slew_degradation, derate, zero_path, logic_levels, path_delay, input_delay, output_delay, clock_uncertainty, incremental, transition_time, capacitance, fanout, clock_skew, launch_clock,

Feedback

launch_clock_latency, capture_clock, capture_clock_latency, bufinvcount, cross_clock, io_path, instance_mcnt, libcell_mcnt.

To show all available columns in a predetermined order, specify the *-columns all* option.

Note: You can specify the column names as minimally-distinct strings. That is, instead of using capacitance, you can use "capa" or even "paci", since no other column name contains that sequence of letters.

`-filters` *`filter_list`*

Specifies a list of filters to apply to the paths analyzed from the timing report. The specified filters are applied with OR logic; all paths matching any specified filter are selected.

Each filter consists of a filter option and its argument. Most filters accept a range of either floating point or integer numbers as an argument. The argument range consists of two numbers separated by a comma. The first number is the lower bound and the second number is the upper bound. You can also specify just one number. In this case, it is interpreted as the lower bound, unless it is preceded by a comma. If the number is preceded by a comma, it is interpreted as the upper bound.

You can specify one or more of the following filters:

- -wns *lower_bound*,*upper_bound*

  Includes all paths that have a worst negative slack (WNS) within the specified floating point range.

- -transition_degradation *lower_bound*,*upper_bound*

  Includes all paths that have their transition degradation ratio (output pin transition time / input pin transition time) within the specified floating point range.

- -slew_degradation *lower_bound*,*upper_bound*

  Includes all paths that have a slew degradation (input pin transition / last stage output pin transition) within the specified floating point range.

- -logic_level *lower_bound*,*upper_bound*

  Includes all paths that have their number of logic levels within the specified integer range.

- -fanout *lower_bound*,*upper_bound*

  Includes all paths that have their worst fanout within the specified integer range.

Feedback

- -input_delay *lower_bound*,*upper_bound*

  Includes all paths that have an external input delay within the specified floating point range.

- -output_delay *lower_bound*,*upper_bound*

  Includes all paths that have an external output delay within the specified floating point range.

- -clock_uncertainty *lower_bound*,*upper_bound*

  Includes all paths that have clock uncertainty within the specified floating point range.

- -zero_path *lower_bound*,*upper_bound*

  Includes all paths with a zero-path margin within the specified floating point range.

- -clock_skew *lower_bound*,*upper_bound*

  Includes all paths that have clock skew within the specified floating point range.

- -path_delay *lower_bound*,*upper_bound*

  Includes all paths that have a path delay within the specified floating point range.

- -transition_time *lower_bound*,*upper_bound*

  Includes all paths that have a transition time within the specified floating point range.

- -capacitance *lower_bound*,*upper_bound*

  Includes all paths that have their worst capacitance within the specified floating point range.

- -derate *lower_bound*,*upper_bound*

  Includes all paths that have their timing derate within the specified floating point range.

- -incremental *lower_bound*,*upper_bound*

  Includes all paths that have an incremental value within the specified floating point range.

- -bufinvcount *lower_bound*,*upper_bound*

Feedback

Includes all paths that have their buffer+inverter count within the specified integer range.

- -io_path *lower_bound*,*upper_bound*

  Include all paths that contain an input or output element in their path. Input/Output elements are: (in), (inout) or (out).

- -cross_clock *lower_bound*,*upper_bound*

  Includes all paths that have different values for the launch and capture clocks. Paths with the same launch and capture clocks will have a value of 0 for this attribute, and paths with different launch and capture clocks will have an attribute of 1.

- -launch_clock *pattern*

  Includes all paths whose launch clock name matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- -capture_clock *pattern*

  Includes all paths whose capture clock name matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- -path_group *pattern*

  Includes all paths whose path group matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- -startpoint *pattern*

  Includes all paths whose startpoint matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- -endpoint *pattern*

  Includes all paths whose endpoint matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- -scenario *pattern*

  Includes all paths whose scenario matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

Feedback

- -instance *pattern*

  Includes all paths that contain an instance matching the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern.

- -file_instance *file_name*

  Includes all paths that contain an instance that matches any of the patterns listed in the specified file (patterns can be separated by space or a newline). Patterns take the same form as those for -instance.

- -libcell *pattern*

  Includes all paths that contain a library cell matching the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern.

- -instance_mcnt *lower_bound*,*upper_bound*

  Includes all paths for which the total count of matches of any of -instance or -file_instance patterns is within the specified range.

- -libcell_mcnt *lower_bound*,*upper_bound*

  Includes all paths for which the total count of matches of any -libcell pattern is within the specified range.

  If you do not specify this option, the following filters are applied:

  ```
  -filters "-wns ,0 -zero_path ,0 -fanout 40
   -transition_degradation 2.0
  -slew_degradation 2.0 -logic_levels 50"
  ```

`-and` *`column_list`*

Specifies a list of filters to apply with AND logic. These filters are applied to the paths that pass the filters specified in the *-filters* option. Paths that match one or more OR filters and all AND filters are included in the result.

For example, if you specify *-filters "-wns ,-3.0 -cross_clock 1"*, the command reports the paths with timing violations where WNS is worse than -3.0 OR -cross_clock is true. If you specify *-filters "-wns ,-3.0 -cross_clock 1" -and wns*, the command reports the paths with timing violations where WNS is worse than -3.0 and -cross_clock is true.

Description

The *query_qor_snapshot* command analyzes timing report files from existing QoR snapshots, applies any specified filters, and displays the results in an appropriate format.

Feedback

You can specify which columns to output with the *-columns* option, and which filters to apply as AND filters with the *-and* option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

Before running the *query_qor_snapshot* command, you must run the *create_qor_snapshot* command to generate the snapshot data, as shown in the following example:

```
prompt> create_qor_snapshot -name place_opt
```

In the following example, the *query_qor_snapshot* command analyzes a QoR snapshot named preroute, which is saved under the snapshot directory and reports the values with WNS between -2.0 and -1.0.

```
prompt> query_qor_snapshot -name preroute -filters "-wns -2.0,-1.0"
```

In the following example, the *query_qor_snapshot* command analyzes QoR snapshot named placeopt, which is saved under the snapshot directory and reports the values with WNS less than -1.0 or fanout over 40.

```
prompt> query_qor_snapshot -name placeopt -filters "-wns ,-1.0 -fanout
 40"
```

The following example shows all paths that have WNS less than zero.

```
prompt> query_qor_snapshot -name timing_report -filters "-wns ,0"
```

The following example shows all paths that have cells with output or input transition time over 2 ns.

```
prompt> query_qor_snapshot -name timing_report \\
   -filters "-transition_degradation 2"
```

The following example shows all paths that have path stages with slew degradation over 3 ns.

```
prompt> query_qor_snapshot -name timing_report \\
   -filters "-slew_degradation 3"
```

The following example shows all paths that have over 50 logic levels:

```
prompt> query_qor_snapshot -name timing_report \\
   -filters "-logic_level 50"
```

The following example shows all paths that have cells with a fanout over 40.

```
prompt> query_qor_snapshot -name timing_report -filters "-fanout 40"
```

Feedback

The following example looks at all timing paths that match the worst negative slack (WNS) filter or zero-path filter. If the WNS violation is more than -10 ns or the path violates zero-path delay.

```
prompt> query_qor_snapshot -name timing_report \\
   -filter "-wns ,-10.0 -zero_path ,0"
```

---

quit!

quits the application without posting an application exit dialog

Syntax

quit!

Arguments

None.

Description

This command is an alternative to the *quit* command. When called with the GUI up, the *quit* command posts an application exit dialog. To avoid having to "deal with" the exit dialog, the user can instead call the *quit!* command which is guaranteed to exit the application without posting a GUI exit dialog.

Examples

```
icc_shell> quit!
```

See Also

- quit

---

quit

Exits the shell.

Feedback

Syntax

```
string quit
```

Arguments

The *quit* command has no arguments.

Description

The *quit* command exits from the application. It is basically a synonym for the *exit* command with no arguments. If there are pending jobs from *redirect -bg, then quit will wait for the jobs to complete before exiting.*

Examples

The following example exits the current session:

```
prompt> quit
```

See Also

- exit

---

r

---

read_3dblox

Reads in one 3DBlox (3D black box) file and its includig files.

Syntax

```
status read_3dblox
   -library library_name
   [-mode mode_type]
   [-common_object_mapping {{die_name mapping_file_name} ...}]
   [-overwrite]
   [-force]
   3dbx_file_name
```

Data Types

```
library_name          string
3dbx_file_name        string
mode_type             string
die_name              string
mapping_file_name     string
```

Feedback

Arguments

`-library` *`library_name`*

This is a required option. Specifies the name of top library to be created.

`file_name`

Specifies one 3dblox file to read.

`-mode` *`mode_type`*

Specifies the mode type. Current support value is: feasibility, physical_constraint, coupe. By default, if user doesn't specify this option, the command runs in normal mode.

In feasibility mode, read_3dblox supports a flow for automatic feasibility analysis. The content of input 3dblox files only include the necessary data for feasibility analysis. There is no tech file or reference library provided in this mode. A new file type 3dbf is defined under a chiplet's external section with the 3dbf_file key. A top level 3dbf file is defined in the TopDef section with the 3dbf_file key. bmap file is reused in this mode, represeting pseudo bumps and their bump types and locations and connections. In feasibility mode, the library won't be saved on disk.

In physical_constraint mode, read_3dblox supports a flow for early chip/package co-design. There is no tech file or bmap file or reference library provided in this mode. New file types defined in this mode: 3dbo, omap and 3dbc. 3dbo(3Dblox Common Object Format) defines 3D pseudo objects. It is in YAML style. omap(3Dblox Common Object Map) defines instances of any object type defined in 3dbo file. It is in CSV style. 3dbc(3Dblox Common Constraint Format) defines constraints with 3Dblox objects(defined in 3dbo and omap).

In coupe mode, read_3dblox supports a flow for custom design with OpenAccess (OA) format. Compared with normal digital design, coupe flow requires OA_tech_lib, OA_marco_lib, OA_schematic_view, OA_layout_view instead of APR_tech_file, LEF file, Verilog file and DEF file. Besides the mentioned info inside 3dbv files, additional SNPS tool required input should be set by the file.3dblox.oa_include_files app option. Check detail accordingly.

`-common_object_mapping {{`*`die_name mapping_file_name`*`} ...}`

Specifies the object mapping file for each die. It is used together with -mode physical_constraint.

mapping_file_name: An absolute file path or a relative path based on *3dbx_file_name* which specifies the object mapping file of the die with *die_name*.

Feedback

object mapping file format: It is in csv style with 2 columns: #common_object_type 3d_object_type

common_object_type is the object_type defined in .3dbo files. 3d_object_type is the database object type supported. Valid values: BUMP/PAD/AM BUMP: cell with design_type "flip_chip_pad" PAD: cell with design_type "flip_chip_pad" and with attribute "is_probe_pad" true AM: cell with design_type "lib_cell" and with attribute "alignment_marker_rule_name" 3dconstraint others: cell with design_type "module"

mapping file example: Bump1 BUMP Bump2 BUMP Pad1 PAD AM_L AM

`-overwrite`

Overwrites existing top library and its reference libraries if the specified library already exists. The option removes all libraries from memory at the beginning of this command.

`-force`

Starting from version 2.5, a virtual connection is mandatory in 3Dblox designs. A virtual connection represents a link between the root cell of a 3Dblox design and the external environment. If no virtual connection is detected, the command halts by default, as required by the 3Dblox specification for versions 2.5 and later.

Enabling this option allows the command to proceed with building the 3Dblox design even if a virtual connection is not defined. However, this may lead to unexpected results, particularly for die stacks with internal bump region definitions, such as incorrect z_offset values.

Description

Reads 3DIC full stack from 3dblox file(s) into a new library. The information is composed of two file types: *.3dbv stores chiplet definition data. *.3dbx stores design stack data. Each design must have only one 3dbx file which includes the necessary 3dbv files.

Chiplets are created in seperated reference libraries according to the tech file they use. The top design is specified in 3dbx file. The command creates chiplet cells in top block. The commnad also creates connection graphs and path assertions.

Examples

The following example reads 3dblox file named my.3dbx into the a new library "myLib".

```
prompt> read_3dblox -library myLib my.3dbx
1
```

Feedback

See Also

- write_3dblox

---

read_aif

Reads in one Advanced Input Format (AIF) file.

Syntax

status *read_aif*

```
[-use_port_name]
[-ignore_assign_nets]
[-hierarchy]
[-pad_to_ref_list {reference_info}]
aif_file_name
```

Data Types

```
reference_info    list
aif_file_name     string
```

Arguments

`-use_port_name`

Specifies the connection name read from AIF file to be treated as port name. If not specified, then the connection name read from AIF file is treated as net name.

`-ignore_assign_nets`

Specifies the connection names present in AIF file to be ignored. No net connection is made for the bump instances in the AIF file. If not specified then connections are made for the bump instances in AIF file.

`-hierarchy`

Specifies the I/O bumps read in across all physically hierarchy levels instead of only in top-level.

`-pad_to_ref_list {`*reference_info*`}`

Allows the reference pad type present in AIF file of bump instances to be remapped to a different reference library bump cell. The *reference_info* includes the following details:

pad_type is the reference pad type present in AIF file. *ref_name* is the different reference library bump cell to which remapping needs to be done. The

Feedback

orientation of bump instance can also be changed than what is present in AIF file by using *orientation*. Valid values of *orientation* are N, W, S, E, FN, FW, FS and FE. If not specified, by default *orientation* is N .

aif_file_name

Specifies name of one AIF file to be read.

Description

This command reads bump instances from the AIF file and creates them in the current design, if not already present. Net connections of the bump instances are made according to the connections given in AIF file and the bump instances are placed at coordinates as given in AIF file.

The coordinates given in AIF file are relative and are adjusted with die width and height (also present in AIF file) and reference library bump cell coordinates to calculate actual placement coordinate.

You can calculate the origin of a bump instance in following equation

x_coordinate = AIF_instance_x + die_width/2 + die_offset_x - Center_xCoordinate
y_coordinate = AIF_instance_y + die_height/2 + die_offset_y - Center_yCoordinate

AIF_instance_x and AIF_instance_y are the x or y-coordinates for the bump instance; die_width and die_height are the WIDTH and HEIGHT in the AIF DIE session. die_offset_x and die_offset_y represent the x or y-coordinates of the lower-left (ll) point of the current_block bbox attribute before read_aif. Center_xCoordinate and Center_yCoordinate are the x or y-coordinates for the reference block center of the bump instance.

For example, in following AIF rules, the AIF_instance_x and AIF_instance_y are 8804.1280 and 6495.8600. die_width and die_height are 21830 and 26130. Center_xCoordinate and Center_yCoordinate are the x/y center coordinate of reference block ubump_N before read_aif.

[DIE] NAME=soc_8ch_phy_die WIDTH=21830.000000 HEIGHT=26130.000000

[PADS] probe_N = SQR 5.000 ubump_N = SQR 5.000 [NETLIST] ;Portname Pad# Type Pad_X Pad_Y Ball# VAA BUMP_A_VAA_0 ubump_N 8804.1280 6495.8600

If the connection column in AIF file for a bump instance is "-", then the connection of the bump instance is removed.

The reference library bump cell and orientation as given in AIF file can be overridden by using -pad_to_ref_list option to read_aif.

If input AIF file was created with -hierarchy option then AIF file is not read in and a warning message is issued.

Feedback

Examples

In the following example, the file my.aif is read and bump instances are created or updated with net connections as given in my.aif

```
prompt> read_aif my.aif
1
```

In the following example, the file my.aif is read and bump instances with reference pad type as BUMPCELL are changed to BUMP2 and the orientation is also changed to south.

```
prompt> read_aif my.aif -pad_to_ref_list { {BUMPCELL BUMP2 S} }
1
```

See Also

- write_aif

---

read_app_options

Reads application options setting data from a binary data file to the current session. The file should be generated by the *write_app_options* command and generally with -non_default option.

Syntax

integer *read_app_options*

```
[-scope scope]
file_name
```

Data Types

```
scope          list
file_name      string
```

Arguments

`-scope scope`

Specifies the application option data scope to be read.

Valid values are global, user_default, and block.

If this option is not specified, all the application option settings in the file, including user-value/user-default, are applied to the new session.

If [-scope global] is specified, only global application option are set. If [-scope user_default] is specified, the user-default of block scope application options are set.

Feedback

If [-scope block] is specified, only block data, user-value of block scope application options are set.

Namely, -scope {global user_default} is specified for reading data without a block and then -scope {block} for the rest after the block is loaded.

file_name

Specifies the file that includes the application options data.

The file should be generated by the *write_app_options* command and generally with -non_default option.

Description

This command reads the application option settings to the current session.

For block scope application options, the user-value is only for the current block.

By default, if there are block scoped values and a current block is not there, then an error is generated and no values are set.

Use -scope {global user_default} to read the data without a block and then use -scope {block} for the rest data after the block is loaded. If the application option is not defined, read_only or the value is invalid in the current session, the application option data is dropped.

Examples

The following example uses read_app_options right after open_block. All application options data can be read.

```
prompt> load_phys_design r4000
prompt> read_app_options app.data
```

The following example uses 2 calls to read.

```
prompt> read_app_options app.data -scope {global user_default}
prompt> load_phys_design r4000
prompt> read_app_options app.data -scope {block}
```

See Also

- write_app_options

- report_app_options

Feedback

- reset_app_options
- set_app_options

---

read_block_connection_file

Reads in a text file containing information on the connectivity between different blocks, and generates a new top-level design based on that.

Syntax

```
string read_block_connection_file
-connections file_name
[-design_name design_name]
[-map_file file_name]
[-ignore_blocks cell_names]
[-create_bus_high_to_low]
```

Data Types

```
design_name     string
file_name       string
cell_names      list
```

Arguments

`-connections file_name`

Specifies the name of the input text file containing the block connection information in a standard format. This file should be in CSV format and must contain the connection data in the form of columns. The supported standard column names are as follows:

- Module Instance
- Module Reference
- Module Port
- Module Port Direction
- Connected Module Instance
- Connected Module Reference
- Connected Module Port
- Connected Module Port Direction

The first row of the file should contain all these column names. Some of these columns are optional and can be omitted, and some default values will be assumed in this case. For example, "Module Port Direction" and "Connected

Feedback

Module Port Direction" columns are not required and a value of "inout" will be assumed for them if they are missing.

If any of the required columns are missing, the tool will error out. Unsupported columns will be ignored without any error. To use your own column names, you can provide a map file through *-map_file* option. The columns could be in any order.

`-design_name` *`design_name`*

Specifies the name of the top-level design created from the connection info. If design name is not specified, it defaults to "TOP". The design must not already exist in the current library.

`-map_file` *`file_name`*

Specifies an optional CSV file which maps custom column names in the connections file to standard Synopsys column names in the form <custom_name>,<standard_name> per line.

For example, the map file contents could be as follows:

```
Main_Ref,Module Reference
Other_Port,Connected Module Port
```

In this example, "Main_Ref" and "Other_Port" are custom column names which can be used in the connections file. The custom column names should not be the same as the standard column names. Also, they must not contain any wildcard or special characters.

`-ignore_blocks` *`cell_names`*

Specifies a list of instances to exclude while creating the top-level netlist. Any line in the input file containing one of these block names will be ignored. Therefore, these blocks will not be instantiated in the final created design.

`-create_bus_high_to_low`

If the file contains bus bit names and ports are created, then this option creates bus in higher bit to lower bit order. By default, buses are always created in low to high order.

Description

The *read_block_connection_file* command reads in a text file containing information on the connectivity between different blocks and creates a top-level design based on the information. The input file can describe any kind of connectivity between multiple modules and from modules to the top-level ports. For example, Module1 <-> Module2, Module2 <-> Module3, Module3 <-> TOP, and so on. In other words, there is no restriction on how many instances are specified at the top level, how many connections are there between all the instances, or how and which instances are connected to the top-level ports. If some

Feedback

particular instance needs to be skipped from the top-level design, it can be specified via the *-ignore_blocks* option.

Each line in the input file represents one connection, whether it is between modules, from a module to the top-level, or even between two top-level ports. The connection from a module to the top-level port (i.e. the "outside world") can be specified by using special keyword "_TOP_" as the Instance as well as the Reference name. If data for a column is missing, the default will be assumed wherever possible. For example, "inout" will be assumed if the "Module Port Direction" column entry is blank. However, some fields might not have default values, these lines will emit warnings and be ignored if the field is blank or incorrect. The order of the rows is not important as there is no dependency of one connection on another.

The top-level design will be created in the current library. If the current library is not set, the command creates a library using the input file name. The top-level design will be named "TOP", unless another name is provided with the *-design_name* option. The name should not be same as any pre-existing design name. The command saves the design into the current library and sets it as the current design. This can be verified with the *list_blocks* and *current_block* commands. If required, you can write out a Verilog netlist by using the *write_verilog* command or do further analysis on this design.

Data consistency checks

The *read_block_connection_file* utility will do multiple checks on the input data in order to generate a correct and meaningful top-level netlist. Some of these checks are as follows:

1. There should not be any missing or extra column entries in each row, unless a default value can be assumed for that column 2. No column should be repeated. 3. The map file, if provided, must have exactly two columns delimited by comma. The first column should contain custom (non-standard) column names and the second should be one of the standard column names. 4. The entries should not contain any special characters like ? or *. 5. The number of columns should be uniform across all the rows. 6. The directions specified for a multiply-occurring port or pin should be consistent across the file. 7. Instances of two different modules should not have the same name. 8. For a connection to a top-level port, both the Module name and Instance name should be the special keyword "_TOP_".

Any line with incorrect data format in any file will be ignored and a corresponding Warning message will be issued. If the data provided in the input text files is not consistent and clean, the tool will fail to generate the top-level netlist and error out with appropriate Error message.

Examples

The following example reads in a CSV file with standard columns and generates a top-level design named "TOP".

Feedback

```
prompt> read_block_connection_file -connections ./test1.csv
Information: Created top-level design 'TOP'. (TLNL-002)
1
```

The following example reads in a CSV file with custom column names, specifies a map file for the column names, specifies the output design name and creates a design in the current library.

```
prompt> read_block_connection_file -connections test2.csv -map_file
 map.csv -design_name MY_TOP
Information: Setting 'My_Ref' as a custom name for column name 'Module
 Reference'. (TLNL-017)
Information: Created top-level design 'MY_TOP'. (TLNL-002)
1
prompt> current_lib
{test2}
prompt> list_blocks
Lib test2 /u/user1/test2 current
  *>  0 MY_TOP.design Sep-07-01:51
1
```

See Also

- write_verilog

---

read_cell_expansion

Reads the cell expansion data from a file to support ASCII flow.

Syntax

int *read_cell_expansion*

```
[-input input_file_name]
[-scale_factor unit_scale]
```

Data Types

```
input_file_name      string
unit_scale           float
```

Arguments

`-input` *input_file_name*

Specifies the name of the input expansion data file. This is a required argument.

Feedback

`-scale_factor` *`unit_scale`*

Specifies the scale factor between tools. This is optional.

Description

The *read_cell_expansion* command reads the cell expansion data from a file.

Examples

The following example reads a cell expansion file and applies it to the current design.

```
prompt> read_cell_expansion -input in.exp
```

See Also

- write_cell_expansion

---

read_def

Reads in one or more DEF (Design Exchange Format) files.

Syntax

```
status read_def
   [-design block]
   [-syntax_only]
   [-no_incremental]
   [-convert_sites conversion_spec]
   [-add_def_only_objects all | cells | nets | ports | none]
   [-skip_pg_net_connections]
   [-traverse_physical_hierarchy]
   file_names
   [-include include_list]
   [-exclude exclude_list]
   [-design_type ype]
```

Data Types

```
block            string
conversion_spec  list
file_names       list
include_list     list
exclude_list     list
type             string
```

Arguments

`-design` *`block`*

Specifies the block into which to read the DEF files.

Feedback

When you specify this option, the tool does not link the block before reading the DEF files. You must ensure that the block is linked before you run the *read_def* command.

By default, the command reads the DEF files into the current block. If the current block is not linked, the tool automatically links it before reading the DEF files.

`-syntax_only`

Indicates that the DEF files are processed only to check the syntax and semantics of the files.

`-no_incremental`

Removes all existing physical annotations from the current block before reading the DEF files. Currently, this option does not support hierarchical designs.

`-convert_sites` *`conversion_spec`*

Specifies the mapping of DEF site names using the following syntax:

`{ {`*`from_site to_site`*`} ...}`

The command converts all DEF rows of site *from_site* to rows of site *to_site*.

`-add_def_only_objects all | cells | nets | ports | none`

Specifies the types of objects that are created by the *read_def* command if they exist in the DEF file but not in the current block. You can specify one or more of the following values, except for *none*, which must be used alone:

- *none* (the default)

  The command does not create cells, nets, or ports if they are not in the current block.

- *cells*

  If a cell exists in the DEF file, but not in the current block, the command creates the cell and connects it to the netlist as specified in the DEF file. The command always creates power and ground net connections; The command creates signal/clock net connections if and only if the pins and the net within the same hierarchy. Otherwise, it ignores signal/clock net connections. If the component name contains hierarchy, the hierarchy must already exist in the design; the command does not create new hierarchical cells.

- *nets*

  If a non-PG net exists in the DEF file, but not in the current block, the command creates the net and connects it to the port specified in the DEF PINS section. If the net name contains hierarchy, the hierarchy must already exist in the design; the command does not create new hierarchical cells.

Feedback

- *ports*

  If a non-PG port exists in the DEF file, but not in the current block, the command creates the port and connects it to the net specified in the DEF PINS section.

- *all*

  This value is equivalent to specifying *cells*, *nets*, and *ports* at the same time.

`-skip_pg_net_connections`

Indicates that the *read_def* command skips the PG net connections in the DEF files.

`-traverse_physical_hierarchy`

Indicates reading design information from the DEF files into a hierarchy design.

```
cells              Only physical-only cells can be created in top
                   or sub block when the option
 "-add_def_only_objects
                   cells", is specified at the same time. Other
                   cells only can be placed at the specified
 location.

nets               Only PG nets can be created in top or sub blocks
                   unless the option "-add_def_only_objects nets"
                   is specified at the same time. Only unconnected
 pins
                   can be connected to the net specified in the DEF
 netlist.
                   All the wiring shapes can be created in the
 block that
                   is associated with the net.

pins               Only top-block pins can be read in the hierarchy
 design.

via definitions, routing rules and bounds
                   They are read into sub block only when they are
 used by
                   wiring or cells in sub block, otherwise, they
 are read
                   into top block.

rows, blockages and tracks
                   They only can be read into top block.
```

file_names

Specifies one or more DEF files to read.

Feedback

`-include` *`include_list`*

Specifies which optional constructs and object types to include when reading the DEF file. When you use this option, only the listed optional constructs and object types are read. These are the optional constructs and object types:

```
blockages
bounds
cells
fills
nets
ports
routing_rules
rows_tracks
scanchains
specialnets
vias
diearea
```

`-exclude` *`exclude_list`*

Specifies which optional constructs and object types to exclude when reading the DEF file. When you use this option, only the listed optional constructs and object types are excluded from being read. The valid values for this option are the same as for the "*-include*" option.

-include and *-exclude* are mutually exclusive options.

`-design_type` *`type`*

An optional argument to specify the design_type for the block. This will override the DESIGN_TYPE property specified in the PROPERTYDEFINITIONS section if present.

Description

Reads design information from the DEF files into the specified block or the current block, based on the *-design* option.

If you use relative path names to specify the DEF files, the command uses the *search_path* variable to locate the files. If you use absolute path names to specify the DEF files, the command does not use the *search_path* variable. To determine the file that the *read_def* command reads, use the *which* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reads the DEF file named my.def into the current block. The command uses the *search_path* variable to locate the DEF file.

Feedback

```
prompt> read_def my.def
1
```

- remove_blocks
- search_path

---

read_design_io

Reads in a delimited text file that contains location, reference cell, and other information for I/O cells. The command creates or updates the specified I/O elements in the design.

Syntax

```
string read_design_io
-file_name_list file_name_list
[-map_file file_name]
[-delimiter_char char]
[-comment_char char]
[-c4_ref_name ref_cell_name]
[-tsv_ref_name ref_cell_name]
[-ubump_ref_name ref_cell_name]
[-bond_pad_def bond_pad_def_name]
[-instance_prefix inst_prefix]
[-overlap_check check_type]
[-create_ports]
[-create_bus_high_to_low]
[-power name_list]
[-ground name_list]
[-die_origin coordinates]
[-die_orientation orientation]
[-cell_origin_type string]
[-pseudo_bumps]
[-eco]
[-attribute name_list]
[-units units_per_micron]
[-verbose]
[-continue_on_error]
[-mark_unconnected_as_dummy]
[-always_set_preferred_pin]
[-force]
```

Feedback

Data Types

```
file_name_list  list
file_name       string
char            string of one character
ref_cell_name   string
bond_pad_def_name string
inst_prefix     string
check_type      string
name_list       list
units_per_micron integer
```

Arguments

`-file_name_list` *file_name_list*

Specifies the names of one or more input I/O design data files. The files must be ASCII files that contain character delimited values. By default, command is uses as the field separator. A different field separator can be defined via the *-delimiter_char* option. Each row should have exactly same number of fields within a file, however, some fields can be empty in some rows.

`-map_file` *file_name*

Specifies a CSV file that maps custom column names in the input file to standard Synopsys column names. Custom column names are specified in the first field, and standard Synopsys column names are specified in the second field, separated by a comma.

For example, the following map file maps four custom column names to their corresponding Synopsys column names.

```
IO_driver name,C4_inst
Ref_Cell,Reference_name
X_COORD,X_origin
Y_COORD,Y_origin
```

`-delimiter_char` *char*

Specifies a single character to be used as the field delimiter in the output files. If not specified, comma is the field delimiter.

`-comment_char` *char*

Specifies a single character to be used as a comment character. When the comment character appears as the first character in a field, that field is ignored.

`-c4_ref_name` *ref_cell_name*

Specifies the name of default C4 bump library cell reference to use if the Reference_name field is empty.

Feedback

`-tsv_ref_name` *`ref_cell_name`*

Specifies the name of default through-silicon via library cell reference to use if the Reference_name field is empty.

`-ubump_ref_name` *`ref_cell_name`*

Specifies the name of micro-bump library cell reference to use if the Reference_name field is empty.

`-bond_pad_def` *`bond_pad_def_name`*

Specifies the name of default bond pad definition for bond pad terminals to use if the Reference_name field is empty.

`-instance_prefix` *`inst_prefix`*

Specifies the prefix to be added before name of instance while generating instance_name automatically. This option is provided when CSV file (in Object_type based format only) have instances with no name.

`-overlap_check` *`check_type`*

Specifies the type of check to be done for physical overlap with existing objects while creating new objects. Possible values are *none*, *nominal* and *strict*. Value of *none* means that no checking will be done and a new object will be created even if any other object or cell exists at that location. With value of *nominal*, following rules will apply:

- Two cells of same type cannot overlap with each other.

- C4 bump can overlap with an existing uBump, TSV or a standard cell.

- uBump can overlap with an existing C4 bump, TSV or a standard cell.

- TSV can overlap with an existing C4 bump or a uBump.

Value of *strict* means that no overlap with any existing cell of any type is allowed. This is an optional option and if it is not specified, the default value of *nominal* is assumed.

`-create_ports`

Create the ports specified in the CSV file if they do not exist at the time of reading the file. If the port names are in bus bit naming format, bus ports will also be created. By default, bus will be created in lower bit to higher bit order.

`-create_bus_high_to_low`

If the file contains bus bit names and ports are created, then this option creates bus in higher bit to lower bit order. By default, buses are always created in low to high order. This option can be specified only with *-create_ports*.

Feedback

`-power` *`name_list`*

When ports or nets are specified in the input CSV file, if they match the names in the given list, their port_type or net_type attribute respecitively will be set to *power*. If the port or net does not exist in the design, it will be created with type *power*. If the port or net already exists, the port_type or net_type attribute will be updated to *power*.

`-ground` *`name_list`*

When ports or nets are specified in the input CSV file, if they match the names in the given list, their port_type or net_type attribute respecitively will be set to *ground*. If the port or net does not exist in the design, it will be created with type *ground*. If the port or net already exists, the port_type or net_type attribute will be updated to *ground*.

`-die_origin` *`coordinates`*

Specifies the coordinates with respect to which the cells (bumps and TSVs) should be placed. In other words, the specified coordinates will be considered as the die origin. This option is optional. If not specified, the lower left corner of the die (interposer) will be considered.

`-die_orientation` *`orientation`*

Specifies the orientation of the Interposer die. If specified, the die is assumed to be rotated accordingly, and hence the coordinates of the newly placed bumps and TSVs will be adjusted appropriately. The allowed values are R0, R90, R180, R270, MX, MXR90, MY, and MYR90. This option is optional. If not specified, the die orientation will be assumed to be R0 (no rotation).

`-cell_origin_type` *`string`*

Specifies what point of the cell should be considered as its origin in order to do its placement. The allowed values are *lower_left* or *center*. The bounding box of the cell will be used to calculate its center. This option is optional. If not specified, the lower left corner of the cell will be considered.

`-pseudo_bumps`

Specifies that the command should read the given CSV file containing pseudo-bump data. The format of the CSV file for pseduo-bumps or bump planning is different than that of the regular or real bumps. Please refer to the section *Pseudo-bump File Details* for more details of the file format.

If the CSV file is in the pseudo-bump format but *-pseudo_bumps* option is not specified, the command will treat it as the real-bump format, and it will give error for unrecognized format. Psuedo-bump and real-bump formats cannot be mixed in the same CSV file. The reading operation will be incremental in nature. If the design already contains pseudo-bumps, the next read_design_io invocation

Feedback

will add more pseudo-bumps in the design. There will be no overlap check for reading in files in this format.

`-eco`

Specifies that the command should read the given CSV file containing bump ECO data. The bump ECO file is generated by the *compare_design_io* command and has a different format than the regular file. The comment character will be assumed to be the pound sign '#'. This option cannot be specified with the options *-units*, *-comment_char* or *-map_file*.

`-attribute` *`name_list`*

Specifies the list of user defined attributes to be read in from the the extra columns. This option is optional. The attribute values specified on each row will be set on the instance for that row after it is created.

Three types of ECO operations are supported, namely Addition, Deletion and Change. The operations specified for each bump or TSV will be applied on the netlist. The objects not specified in the ECO file will not be updated. Instances specified for change (C) or deletion (D) must exist in the design. Instances specified for addition (A) must not exist in the design.

`-units` *`units_per_micron`*

If the length unit used in the CSV file is different from that of the design library, this option can be used to specify the custom unit for length. When specified, the distance values, i.e. X/Y coordinates specified in the CSV will be divided by this number to derive the distance value in microns. The value must be an integer >=1. This is an optional option. If not specified, the distance values will be assumed to be in the same unit as the current library.

`-verbose`

Outputs detailed information

`-continue_on_error`

If this option is specified, and the reader encounters a syntax error, it will ignore that row with a Warning and continue processing the rest of the rows. So all the valid rows in the file will be considered and netlist will be updated accordingly

`-mark_unconnected_as_dummy`

If this option is specified, reader will mark those objects as dummy or temporary which have no net assigned which means neither net name nor port name is given in the CSV file for those objects. This can be verified by checking the value of is_dummy attribute on such objects. This can be done for pseudo_bumps as well by specifying this option with -pseudo_bumps.

Feedback

`-always_set_preferred_pin`

If this option is specified, the command will try to set the preferred_pin on the port even if it already exists in the design.

`-force`

If this option is specified, the command will create an instance even if it is specified to be outside of the die area, and DIO-004 error will not be printed.

Description

The *read_design_io* command reads one or more input files in character delimited format and modifies the current design based on the I/O design data in those files. This command requires an existing NDM library and design to be created and opened, and it will not create a new NDM design. The existing design may or may not already contain design objects, floorplan, etc. Based on the field map and provided I/O object data in the input file, the command can create, place, and connect the following design objects:

- C4 bump cells

- Microbump cells

- Through-Silicon Vias (TSVs)

- Bond Pad terminals

If a specified I/O object does not exist, it will be created. Otherwise, its placement and connection will be updated based on the file data. The input file is in as ASCII file that is character delimited. The default character delimiter is a comma. A different field separator can be specified with the *-delimiter_char* option. Each row should have exactly the same number of fields within a file, however, some fields can be empty in some rows.

The following standard columns can be specified in the input file of Object_type based format:

- Instance_name

- Object_type

- Reference_name

- X_origin

- Y_origin

- Orientation

- Port_name

- Net_name

- Comments

Feedback

Values of Object_type column can be any of C4, Ubump, Bond_pad, TSV, Pseudo_bump.

The file in older format generated using write_design_io -object_type_column false can also be read in.

Any additional columns are ignored and the tool issues a warning message. The first row of the input file must be a header row that contains the column names. Each row contains information for one I/O design object. If there are multiple rows for the same object, the later rows will overwrite the previous connection. If the column names in the CSV files are not same as the standard column names specified above, a mapping from the custom column names to these standard names can be provided with the *-map_file* option.

If the reference name for the C4, ubump, TSV or bond pad terminal objects are not provided, the default values will be used when creating the objects as defined with the *-c4_ref_name*, *-ubump_ref_name*, *-tsv_ref_name*, and *-bond_pad_def* options. A specified object reference in the input file will override the default or placement information for that object.

If a cell is already in the design, it will be placed to the location specified by the X_origin and Y_origin fields. If the location data is incomplete (for example, X-origin exists but Y-origin is missing), both columns are skipped. If a cell does not exist, it will be created at the specified location or by default at (0,0). The command will skip the cell and issue a warning if the following are true:

- A reference is not available or cannot be found
- The specified xy coordinates are outside the die bounds
- The specified object overlaps with an existing object

If connectivity is different from the current netlist, the tool will skip the connection information. If connectivity is impossible due to a missing port or some other problem, then no connection will be made.

Any missing, invalid or inconsistent data on a row will cause an error and the I/O object will not be created. If the command encounters an error while parsing the input file, but the "sh_continue_on_error" application variable is "true", the command ignores the row and continues parsing the remaining lines. The supplied data does not have to produce a complete design.

The contents of "Comments" column have no affect on the command. However, ensure that the comment string does not contain a delimiter character (for example, a comma). If a comment character has been specified with the *-comment_char* option, data fields can be defined as comments which will be ignored by the command.

If multiple input files are provided, the subsequent files will overwrite the design information of objects that were specified in previous files. So the order in which the files are specified is important and affects the final result. Different input files can have different number of columns and different order.

Feedback

Field Map File Details

If the input file contains custom names for fields instead of the Synopsys standard names, a mapping file can be provided via the *-map_file* option. Use the mapping file to create a map between the custom field names and the corresponding Synopsys standard name for the field.

Each line in the map file contains exactly two strings separated by a comma. The first string is a user-defined field string and the second string is a Synopsys keyword. The order of lines does not matter. If the second string is not recognized, the line is ignored with a warning message.

The following map file maps the standard C4_inst field name to "IO_driver", and maps the standard Reference_name field name to "Ref_Cell".

```
IO_driver,C4_inst
Ref_Cell,Reference_name
```

The custom field names should not be same as the standard field names. Also, they must not contain any wildcard or special characters.

Pseudo-bump File Details

The CSV file for pseudo-bumps or bump planning is split into two sections. The first section contains the data for the bump regions. It starts with the line “Start section,Bump regions” and ends with “End section,Bump regions”. It contains one row per bump region. The following columns are supported. - Name : Name of the region. This is compulsory. - Boundary : List of (X,Y) coordinate pairs. This is compulsory. - Pitch_X : List of cyclical distances between i’th and (i+1)th columns. This is compulsory. - Pitch_Y : List of cyclical distances between i’th and (i+1)th rows. This is compulsory. - Pattern_offset_X : delta-X from ll of the bump region to the start of the pattern - Pattern_offset_Y : delta-Y from ll of the bump region to the start of the pattern - Row_stagger_X : List of cyclical distances for delta-X for start of a row - Column_stagger_Y : List of cyclical distances for delta-Y for start of a column - Orientation : One of the eight possible values : R0, R90, R180, R270, MX, MXR90, MY, MYR90. A blank field defaults to R0 - Bump_shape : Default shape applicable to pseudo-bumps in this region, unless overridden by individual pseudo-bump. Allowed values are : triangle, square, pentagon, hexagon, septagon, octagon, circle. This is optional and default value is octagon. - Bump_radius : Default radius of pseudo-bumps in this region, unless overridden by individual pseudo-bump. This is compulsory. - Is_backside : Whether the bump region is on the back-side. This is optional. Default is false. - Port_pattern : The 2d pattern of port names which the pseudo-bumps are connected to - Net_pattern : The 2d pattern of net names which the pseudo-bumps are connected to

The second section contains the data for the pseudo-bumps and has one row per pseudo-bump. This section starts with the line “Start section,Pseudo-bumps” and ends with “End section,Pseudo-bumps”. The following columns are supported in Object_type based format of CSV file.

Feedback

- Instance_name : Instance name is of format Region_name_PB_Column_Row for structured (non-freeform) pseudo-bumps. where Region_name is the name of the region in which this pseudo-bump resides, Column is the column index number (starting from the left at 0 and going up) and Row is the row index number (starting from the bottom at 0 and going up) Instance name is of format Region_name_PB_Id for freeform pseudo-bumps. where Region_name is the name of the region in which this pseudo-bump resides, and Id is some identifier string. However, if there is only one bump region specified in the file, then the instance name does not need to follow this format, as the command automatically assumes the pseudo-bump to be a part of that single bump region. - Object_type : Pseudo_bump - X_origin, Y-origin : Location of the center of the bump - Orientation : One of the eight possible values : R0, R90, R180, R270, MX, MXR90, MY, MYR90. A blank field defaults to R0 - Net_name : Name of the net connected to this bump. - Port_name : Name of the top-level logical port that this pseudo-bump is connected to - Shape : Can be one of : triangle, square, pentagon, hexagon, septagon, octagon, circle. If not specified, it defaults to the one specified for the corresponding region. - Radius : Radius value in user units. If not specified, this defaults to the one specified for the corresponding region. - Is_hole : Can be either “true” or “false”. If left blank, it defaults to “false” - Is_probe_pad : Same as above - Is_dummy: Same as above - Is_default: Same as above

The file in older format generated using write_design_io -object_type_column false -pseudo_bumps can also be read in.

The Bump region section must be declared before the Pseudo-bumps section. All keywords like section names, column names, etc. are case sensitive. The columns (fields) in both the sections can be in any order.

Examples

The following example reads in a CSV file with standard column names and creates or updates I/O design objects at the top level.

```
prompt> read_design_io -file_name_list ./test1.csv
Information: 6 lines processed from 1 files.
Information: 0 C4 bumps created. 0 C4 bumps placed.
Information: Location of 1 existing C4 bumps updated.

read_dff_connections

Reads data flow flylines connections information from a specified file.

Syntax

```
status read_dff_connections
[-filename file_name]
[-threshold threshold_value]
```

Feedback

Data Types

file_name	string
threshold_value	float

Arguments

`-filename` *file_name*

Specifies the file name from which the data flow flylines connections information is read in.

`-threshold` *threshold_value*

Specifies the minimum percentage threshold value of matching while reading the file. This percentage is described as the ratio of matching-paths to total-paths. By default, no mismatch is allowed. Thus, the default threshold is 1.

Description

This command reads the data flow flylines connections information from a file. The data flow flylines connections file must have been created by the *write_dff_connections* command. When reading the data flow flylines connections file, you need to ensure that the bounds and macros cell list are the same as when the data flow flylines connections file was written. Otherwise, you need to rerun the *compute_dff_connections* command followed by the *write_dff_connections* command to save the latest data flow flylines connections file.

Examples

The following example reads a data flow flylines connections file named f1.

```
prompt> read_dff_connections -filename f1
```

The following example reads a data flow flylines connections file named f1 with and without the threshold value.

```
prompt> read_dff_connections -filename f1
Error: Loading DFF Connections canceled - success rate 0.985816 is below
 required
threshold: 1.000000. (DPUI-251)
0
prompt> read_dff_connections -filename f1 -threshold 0.95
Warning: Loading DFF Connections - errors detected, but threshold
 0.985816 is above
required threshold: 0.950000. (DPUI-252)
1
```

---

read_drc_error_file

Creates an error data from the given DRC error file.

Please note that, with this command, the error cell is created but not saved. Thus, the error cell has unsaved data. To post-process or overwrite the error cell, use the following commands:

save_block (To save the error cell)

close_drc_error_data -force (To close the error cell)

remove_drc_error_data -force (To remove the error cell)

Syntax

status *read_drc_error_file*

```
[-drc_type type]
[-error_data error_data_name]
[-select_rules rules]
[-skip_lines_starting_with keywords]
[-file drc_file]
```

Data Types

```
type              string
error_data_name   string
rules             list
keywords          list
drc_file          string
```

Arguments

`-drc_type type`

Type of the drc_file. Valid value is: calibre.

`-error_data error_data_name`

Name to assign to the error data.

For calibre drc report, if this option is not specified, <cell_name>.err is used by default, where <cell_name> is found inside the drc report file.

Feedback

If this option is not specified and <cell_name> is not found, this command will abort.

`-select_rules` *rules*

Specify the rules patterns.

`-skip_lines_starting_with` *keywords*

Specify the keywords to skip lines starting with keywords.

`-file` *drc_file*

The DRC error report to read in. This is a required option.

Description

The *read_drc_error_file* command takes a DRC error report as input and creates error data. The error data can then be loaded with the error browser.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following is an example of how to run the *read_drc_error_file* command.

```
prompt> read_drc_error_file -drc_type calibre

prompt> read_drc_error_file -error_data_name xyz.err

prompt> read_drc_error_file -select_rules {M*}

prompt> read_drc_error_file -file drc_report
```

---

read_feature_tables

Reads single or multiple feature tables from CVS or JSON files, or ML database.

Syntax

read_feature_tables

```
-tables list_of_table_names
-all_tables
[-from_csv list_of_file_names]
[-from_json list_of_file_names]
[-from_ml_db]
```

Feedback

Data Types

list_of_table_names	list
list_of_file_names	list

Arguments

`-tables` *list_of_table_names*

Specifies the names of the feature tables to be read. If the table already exists, it is overwritten, otherwise a new table is created.

`-all_tables`

This option is mutually exclusive with *-tables*, and it can only be used together with *-from_ml_db*. With this option and *-from_ml_db* specified, this command reads all features tables from ML database.

`-from_csv` *list_of_file_names*

Specifies the names (paths) of the CSV files to be read from. The number of this option should match the number of *-tables* option.

`-from_json` *list_of_file_names*

Specifies the names (paths) of the JSON files to be read from. The number of this option should match the number of *-tables* option.

`-from_ml_db`

When specified this command reads the specified feature tables from ML database. This option is mutually exclusive with *-from_csv* and *-from_json* options.

Before reading from database, the database must be open using the *open_ml_db* command. The features tables are read from the working record of the database.

Description

This command reads feature tables from CVS or JSON files, or ML database. If the feature tables need to be read from database, this command should work with database related commands: *open_ml_db*, *set_working_ml_db_record*.

Examples

The following example shows the command reads two feature tables from CSV files.

```
prompt> read_feature_tables -tables {table1 table2} \\
   -from_csv {table1.csv table2.csv}
```

The following example shows the command reads all feature tables from ml database.

Feedback

```
prompt> open_ml_db test_db -datastore serverless
prompt> read_feature_tables -all_tables from_ml_db
```

---

read_fill_from_stream

Reads FILL data from one GDSII/OASIS file into the existing (current) block.

Syntax

collection *read_fill_from_stream*

```
[-layer_map layer_map_file_name]
[-block_map block_map_file_name]
[-layer_map_format icc2 | icc_default | icc_extended]
[-read_always true | false]
[-merge_action append | replace_layer | replace_all]
[-ignore_missing_layers]
[-mapped_layers_only]
[-include_active_fill]
-gds | -oasis file_name
```

Data Types

```
layer_map_file_name  string
file_name            string
```

Arguments

`-layer_map layer_map_file_name`

Specifies a layer mapping file that customizes the translation of layer, data type, and purpose between the GDSII/OASIS file and tool's data model. For details, see "Layer Mapping File" in the DESCRIPTION section.

Feedback

`-layer_map_format icc2 | icc_default | icc_extended`

Specifies the format of the layer mapping file. This option allows the command to accept an IC Compiler layer mapping file. These are the allowed settings:

- *icc_default*: IC Compiler default layer mode, system layers 188-255
- *icc_extended*: IC Compiler extended layer mode, system layers 4001-4095
- *icc2*: IC Compiler II layer mapping file format (default)

`-read_always true | false`

Specifies whether the command always reads in layers from the GDSII/OASIS file, even when those layers do not already exist in the technology of the IC Compiler II library:

- *true*: The command reads in layers that do not already exist in the IC Compiler II library by creating new layers in the library's technology.
- *false* (the default): If a GDSII/OASIS layer does not already exist in the technology of the IC Compiler II library, the command reports an error and stops working by default. However, you can allow processing to continue by using the *-ignore_missing_layers* option.

A "read_always" entry in the layer mapping file for a particular layer has higher priority than the *-read_always* command option setting.

`-merge_action append | replace_layer | replace_all`

Specifies how to handle conflicts between identically named blocks:

- *append*: Appends both passive and active fill data in the top cell to the current block when the top cell name in the stream file is same with the current block name, otherwise, create a new block and a new fill cell in the top block to reference it, import the data to the new block. When the sub cell in the stream file has the same name with existing sub block name, always rename and create a new block for it and import the data to the new block.
- *replace_layer*: Replaces all the passive and active fill shape on the layers that are present in the incoming stream file with that of new fill shapes on the layers in the steam file (not support hierarchical fill structures in the stream file)
- *replace_all*: Overwrite the existing passive and active fill data (the default)

`-ignore_missing_layers`

Specifies that the command will continue to work even when an incoming GDSII/OASIS layer is not present in the technology of the IC Compiler II library. In

Feedback

that case, the command ignores the GDSII/OASIS layer and issues a warning message.

`-mapped_layers_only`

Specifies that the command reads only the objects for which a mapping is defined in the layer mapping file, from the GDSII/OASIS layer-datatype pair of the object to a layer-datatype pair in the IC Compiler II data model. If such a mapping does not exist, the command reports a warning and ignores the object. If the object is on a missing layer and the *-ignore_missing_layers* option is used, the object is ignored and no warning is issued.

`-include_active_fill`

Specifies that the command reads in active fill data.

`-gds | -oasis` *`file_names`*

Specifies the names of the GDSII/OASIS input files. Use -gds to specify GDSII files and -oasis to specify OASIS files. At present,-gds and oasis are mutually exclusive.

Description

The *read_fill_from_stream* command reads one GDSII/OASIS stream file and dumps only FILL into BLOCK outside of the existing In-Design Flow.*read_fill_from_stream* command dumps FILL data a current(existing) IC Compiler II library.

To find file that have relative pathnames, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path*. Files that have absolute pathnames are loaded without using the *search_path* variable. To determine the path to a particular file name, use the *which* command.

If the GDSII/OASIS file has data other than FILL data , it is recommended to use command options *-read_always* with value *false* and *-mapped_layers_only* with a layer map which has mapping of FILL layer only. /fIuse_type/fP as "area_fill" have to be specified for each layer entry in layer map file otherwise particular layer entry will be ignored.

Format

tool_layer_number:tool_data_tyep:area_fill gds_layer_number:gds_data_type

Layer Mapping File

By default, the *read_fill_from_stream* command maintains the original layer numbers of the GDSII/OASIS files as it builds the library in the IC Compiler II database.

Feedback

You can optionally provide a layer mapping file to specify the mapping of layers and data types between the GDSII/OASIS layers and the IC Compiler II database. This is the mapping file format:

```
; single line comment
[read_always { true | false [-mapped_only | -ignore_missing_layers ] } ]
[blockage_as_zero_spacing {true|false}]
[cell_prop_attribute attribute_number]
[net_prop_attribute  attribute_number]
[pin_prop_attribute  attribute_number]
[object_type] tool_layer_number[:tool_purpose][:use_type][:mask_type] \\
  gdsii_layer_num[:gdsii_data_type]
```

For example,

```
; This is my layer mapping file
                    ;
     84       92    ; ICC2 layer 84 = GDSII/OASIS layer 92
                    ;
     59       69:3  ; ICC2 layer 59 = GDSII/OASIS layer 69, data type 3
                    ;
     17:1    117:3  ; ICC2 layer 17, purpose 1 = GDSII/OASIS layer 117,
 data type 3
                    ;
data 33:0:*:*  1:2  ; ICC2 data on layer 33, purpose 0, any use type,
                    ;  any mask type = GDSII/OASIS layer 1, data type 2
text 33:0:*:*  1:4  ; ICC2 text on layer 33, purpose 0, any use type,
                    ;  any mask type = GDSII/OASIS layer 1, data type 4
                    ;
; all other layers and data types match between ICC2 and GDSII
```

In each line, any text after a semicolon ";" is a comment.

The *read_always* statement determines how the *read_fill_from_stream* command handles differences between GDSII/OASIS layers and IC Compiler II database layers:

- *read_always true*: The command always reads in every layer. If the layer is not already present in the IC Compiler II technology, the command adds a new layer to the technology
- *read_always false*: If the layer does not already exist in the IC Compiler II technology, an error occurs and processing stops.
- *read_always false -ignore_missing_layers*: If the layer does not already exist in the IC Compiler II technology, the command ignores that layer, issues a warning, and continues processing.
- *read_always false -mapped_layer*: The command reads only the layers defined in the layer mapping file. If any incoming layer is not defined in the layer mapping file, the command ignores that layer, issues a warning, and continues processing.

Feedback

The *blockage_as_zero_spacing* statement determines how the *read_gds* command interprets GDSII/OASIS blockage layers, as either zero-spacing or design-rule-spacing guides. Use *blockage_as_zero_spacing true* for zero-spacing guides. The default is to interpret blockages as design-rule-spacing guides.

The *cell_prop_attribute*, *net_prop_attribute*, and *pin_prop_attribute* statements specify the property attribute numbers used for storing cell instance, net, and pin names in the GDSII/OASIS file. For example, the statement "net_prop_attribute 5" causes the *write_gds* command to write out net names of objects as property attribute 5 in the GDSII/OASIS file. These statements in the layer mapping file have higher priority than the corresponding *write_gds* command options, *-instance_property*, *-net_property*, and *-pin_property*.

Each field of the layer mapping line is separated by a colon ":". Each field can be an explicit value, an asterisk "*" wildcard character, or left blank. An asterisk or black space indicates any value.

A more specific rule priority than a more general rule. For example, the rule "5:3 8", has higher priority than "5 7". If conflicting rules are specified in different lines (for example, first "6:2 4" and then "6:2 7"), the last one in the file is used and the earlier one is ignored.

The optional *object_type* keyword at the beginning of a layer mapping line applies only to the *write_gds* command.

tool_layer_number is the layer number in the IC Compiler II database, an integer.

tool_purpose is the purpose number in the IC Compiler II database, an integer.

use_type is the usage type in the IC Compiler II database, which is one of the following:

```
power
  ground
  clock
  signal
  boundary
  hard_placement_blockage
  soft_placement_blockage
  routing_blockage
  area_fill
```

mask_type is the mask type of the shape in a multiple-patterning technology. For a metal layer, the following mask types are supported:

```
mask_one
  mask_two
  mask_three
  same_mask
```

For a VIA cut layer, the following additional mask types are supported:

```
MASK_FOUR
  MASK_FIVE
```

Feedback

```
MASK_SIX
...
MASK_FIFTEEN
```

gdsii_layer_num is the layer number of the geometry or TEXT in the GDSII file, an integer.

gdsii_data_type is the data type number of the geometry or TEXT in the GDSII file, an integer.

Examples

The following example reads the design.gds GDSII file

```
prompt> read_fill_from_stream -gds design.gds
1
```

See Also

- search_path

---

read_gds

Reads one or more GDSII files into the library workspace for library preparation.

Syntax

collection *read_gds*

```
[-library lib_name]
[-layer_map layer_map_file_name]
[-block_map block_map_file_name]
[-merge_action add | overwrite | update | ignore]
[-keep_text]
[-trace_option trace_option]
[-trace_connectivity_limit trace_limit]
[-trace_all_layers_for port_names]
[-net_property net_property_value]
[-cell_property cell_property_value]
[-pin_property pin_property_value]
[-via_property via_property_value]
[-ascii ascii_file_name]
[-verbose]
[-centerline_boundary]
[-mask_fixed]
[-layer_map_format icc2 | icc_default | icc_extended]
[-read_always true | false]
[-ignore_missing_layers]
[-ignore_connectivity_layers layers]
[-disable_link]
[-mapped_layers_only]
[-top_design_name top_design_name]
[-trace_top_only]
```

Feedback

```
[-top_design_type design_type]
[-disable_force_link]
file_names
```

Data Types

```
lib_name              string
layer_map_file_name   string
block_map_file_name   string
trace_option          string
port_names            string
trace_limit           integer
net_property_value    integer
cell_property_value   integer
pin_property_value    integer
via_property_value    integer
ascii_file_name       string
file_names            list of strings
layers                list of strings
```

Arguments

`-library` *lib_name*

Specifies the name of a library (or a single-library collection) in which to add the GDSII data. If the library already exists, the GDSII data is added to that library. Otherwise, the command creates a new library with the specified name and adds the GDSII data to that library. By default, the command uses the library name field of the GDSII file.

`-layer_map` *layer_map_file_name*

Specifies a layer mapping file that customizes the translation of layer, data type, and purpose between the GDSII file and tool's data model. For details, see "Layer Mapping File" in the DESCRIPTION section.

`-block_map` *block_map_file_name*

Specifies the name of a block mapping file. The file specifies whether to add, ignore, overwrite, retain or merge specific blocks; and how each block is mapped into the database with respect to block type, site name, and centerline boundary. For details, see "Block Mapping File" in the DESCRIPTION section.

`-merge_action add | overwrite | update | ignore`

Specifies how to handle conflicts between identically named blocks:

- *add*: Adds a new block to the database using a new name (the default)
- *overwrite*: Replaces any existing block with the same name

Feedback

- *update*: Merges the geometries of the block into the existing block in the database
- *ignore*: Ignores the new GDSII block and keeps the exiting block

`-keep_text`

Specifies whether to keep text boxes after the pins are identified. This option determines whether text shapes are kept or removed after connectivity tracing. The default is to remove the text boxes. The text itself is always kept.

`-trace_option` *`trace_option`*

Specifies the conditions for performing connectivity tracing, in which the tool traces overlapping geometries to determine the extent of each net. These are the possible settings:

- *none*: Prevents connectivity tracing
- *pins_only*: Identifies pin shapes that directly overlap the text shapes, but does not propagate the pin information to the shapes that do not directly overlap with the text shapes, even when they overlap the identified pin shapes
- *all_layers*: Propagates the connectivity across all layers
- *same_layer*: Traces the connectivity only on the same layer
- *auto*: Traces the connectivity using the *same_layer* or *pins_only* setting, depending on the object type:

```
Object type       Trace option setting used in "auto" mode

abstract:         pins_only
analog:           pins_only
black_box:        pins_only
corner:           same_layer
cover:            same_layer
diode:            same_layer
end_cap:          same_layer
feedthrough:      same_layer
fill:             same_layer
filler:           same_layer
flip_chip_driver: same_layer
flip_chip_pad:    same_layer
lib_cell:         same_layer
macro:            pins_only
module:           pins_only
pad:              same_layer
pad_spacer:       same_layer
well_tap:         same_layer
```

Feedback

```
package:          pins_only
pcb:              pins_only
rdl_fanout:       pins_only
```

The default trace option setting is *auto*.

`-trace_connectivity_limit` *`trace_limit`*

Specifies the maximum number of geometries to be traced for connectivity. If the number of geometries traced exceeds this limit, then tracing falls back to same-layer-tracing only. By default, there is no limit.

`-trace_all_layers_for` *`port_names`*

Specified ports will be traced for all the layers. It has lower priority than the *-ignore_connectivity_layers* command option setting.

`-net_property` *`net_property_value`*

Extracts the net name as a property attribute with the specified attribute number in the GDSII stream. By default, no net names are extracted from GDSII property attributes.

`-cell_property` *`cell_property_value`*

Extracts the instance name as a property attribute with the specified attribute number in the GDSII stream. By default, no instance names are extracted from GDSII property attributes.

`-pin_property` *`pin_property_value`*

Extracts the pin name as a property attribute with the specified attribute number in the GDSII stream. By default, no pin names are extracted from GDSII property attributes.

`-via_property` *`via_property_value`*

Extracts the via and via matrix property with the specified attribute number in the GDSII stream. By default, no via or via matrix property is extracted from GDSII file.

`-ascii` *`ascii_file_name`*

Writes the GDSII data to the specified text file in ASCII format. By default, the command does not write out the GDSII data.

`-verbose`

Reports additional information on the special handling of data related to the layer, data type, or block mapping.

Feedback

`-centerline_boundary`

Creates the boundary for each block by joining line segments that pass through the centers of the pins in the design view of the block. By default, the boundary is the bounding box of block.

`-mask_fixed`

Marks the library as not mask shiftable by setting the library's is_mask_shiftable attribute to false in the database. This prevents mask shifting from being performed in the library in a double-patterning technology.

`-layer_map_format icc2 | icc_default | icc_extended`

Specifies the format of the layer mapping file. This option allows the command to accept an IC Compiler layer mapping file. These are the allowed settings:

- *icc_default*: IC Compiler default layer mode, system layers 188-255
- *icc_extended*: IC Compiler extended layer mode, system layers 4001-4095
- *icc2*: IC Compiler II layer mapping file format (default)

`-read_always true | false`

Specifies whether the command always reads in layers from the GDSII file, even when those layers do not already exist in the technology data of the library:

- *true*: The command reads in layers that do not already exist in the library by creating new layers in the library's technology data.
- *false* (the default): If a GDSII layer does not already exist in the technology data of the library, the command reports an error and stops working by default. However, you can allow processing to continue by using the *-ignore_missing_layers* option.

A "read_always" entry in the layer mapping file for a particular layer has higher priority than the *-read_always* command option setting.

`-ignore_missing_layers`

Specifies that the command will continue to work even when an incoming GDSII layer is not present in the technology data of the library. In that case, the command ignores the GDSII layer and issues a warning message.

`-ignore_connectivity_layers` *layers*

Specifies the layers on which shapes are ignored while tracing connectivity. If there is text on the specified layer, it is given higher priority. The terminal is created on the layer.

Feedback

`-disable_link`

Disable the link. It is recommended to use this option when only layout view is needed. By default, *read_gds* always does the link.

`-mapped_layers_only`

Specifies that the command reads only the objects for which a mapping is defined in the layer mapping file, from the GDSII layer-datatype pair of the object to a layer-datatype pair in the database. If such a mapping does not exist, the command reports a warning and ignores the object. If the object is on a missing layer and the *-ignore_missing_layers* option is used, the object is ignored and no warning is issued.

`-top_design_name` *`top_design_name`*

Specifies to trace only the top design, even several top designs are available from a GDSII file.

`-trace_top_only`

Specifies to trace only a top design. Its reference designs won't be traced anymore. Without setting this option, all the top designs and their reference designs are to be traced.

`-top_design_type` *`design_type`*

Specifies the design type of the top design. The valid values for this option are *abstract*,*analog*, *black_box*, *corner*, *cover*, *diode*,*end_cap*, *feedthrough*, *fill*, *filler*, *flip_chip_driver*, *flip_chip_pad*, *lib_cell*, *macro*, *module*, *pad*, *pad_spacer*, *well_tap*, *package*, *die*, and *interposer*.

It is a shortcut for *-block_map* and overrides a rule specifed by *-block_map*. It is appropriate for a huge GDSII file with only a top design. It doesn't take effect when it's not set.

`-disable_force_link`

Specifies linker to first check if the design is linked and if it is, linker would do nothing. By default, linker even if it is linked already, and linker to examine each reference and bind it again, based on the current reference libraries.

This option need not to be set only reference libriaries have been set like by *set_ref_libs* before read_gds

`file_names`

Specifies the names of the GDSII input files.

Description

The *read_gds* command reads one or more GDSII stream files into the library manager and converts the data to NDM format for library preparation purposes. Each usage of the

Feedback

read_gds command creates a new library unless the *-library* option specifies the name of an existing library.

The GDSII data does not define port type information. To prevent library preparation errors, you should set the port type mapping by using the *file.gds.port_type_map* application option.

To find files that have relative pathnames, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path*. Files that have absolute pathnames are loaded without using the *search_path* variable. To determine the path to a particular file name, use the *which* command.

Layer Mapping File

By default, the *read_gds* command maintains the original layer numbers of the GDSII files as it builds the library in the database.

You can optionally provide a layer mapping file to specify the mapping of layers and data types between the GDSII layers and the database. You can use the same mapping file for both the *read_gds* and *write_gds* commands. This is the mapping file format:

```
; single line comment
[read_always { true | false [-mapped_only | -ignore_missing_layers ] } ]
[blockage_as_zero_spacing {true|false}]
[cell_prop_attribute attribute_number]
[net_prop_attribute  attribute_number]
[pin_prop_attribute  attribute_number]
[via_prop_attribute  attribute_number]
[object_type] tool_layer_number[:tool_purpose][:use_type][:mask_type] \\
  gdsii_layer_num[:gdsii_data_type]
```

For example,

```
; This is my layer mapping file
                    ;
     84       92    ; ICC2 layer 84 = GDSII layer 92
                    ;
     59       69:3  ; ICC2 layer 59 = GDSII layer 69, data type 3
                    ;
     17:1    117:3  ; ICC2 layer 17, purpose 1 = GDSII layer 117, data
 type 3
                    ;
data 33:0:*:*  1:2  ; ICC2 data on layer 33, purpose 0, any use type,
                    ;  any mask type = GDSII layer 1, data type 2
text 33:0:*:*  1:4  ; ICC2 text on layer 33, purpose 0, any use type,
                    ;  any mask type = GDSII layer 1, data type 4
                    ;
; all other layers and data types match between ICC2 and GDSII
```

In each line, any text after a semicolon ";" is a comment.

Feedback

The *read_always* statement determines how the *read_gds* command handles differences between GDSII layers and database layers:

- *read_always true*: The command always reads in every layer. If the layer is not already present in the library's technology data, the command adds a new layer to the technology data.
- *read_always false*: If the layer does not already exist in the library's technology data, an error occurs and processing stops.
- *read_always false -ignore_missing_layers*: If the layer does not already exist in the library's technology data, the command ignores that layer, issues a warning, and continues processing.
- *read_always false -mapped_layer*: The command reads only the layers defined in the layer mapping file. If any incoming layer is not defined in the library's technology data, the command ignores that layer, issues a warning, and continues processing.

The *blockage_as_zero_spacing* statement determines how the *read_gds* command interprets GDSII blockage layers, as either zero-spacing or design-rule-spacing guides. Use *blockage_as_zero_spacing true* for zero-spacing guides. The default is to interpret blockages as design-rule-spacing guides.

The *cell_prop_attribute*, *net_prop_attribute*, *pin_prop_attribute*, and *via_prop_attribute* statements specify the property attribute numbers used for storing cell instance, net, pin names, via attribute in the GDSII file. The specified value for the properties should be distinct while generating the GDSII file. For example, the statement "net_prop_attribute 5" causes the *write_gds* command to write out net names of objects as property attribute 5 in the GDSII file. These statements in the layer mapping file have higher priority than the corresponding *write_gds* command options, *-instance_property*, *-net_property*, *-pin_property*, and *-via_property*.

After you write a GDSII file with these properties, when you read the file back into the tool with the *read_gds* command, the original cell names are restored, and the pins and nets are properly identified without the tool spending time on connectivity tracing.

Each field of the layer mapping line is separated by a colon ":". Each field can be an explicit value, an asterisk "*" wildcard character, or left blank. An asterisk or black space indicates any value.

A more specific rule priority than a more general rule. For example, the rule "5:3 8", has higher priority than "5 7". If conflicting rules are specified in different lines (for example, first "6:2 4" and then "6:2 7"), the last one in the file is used and the earlier one is ignored.

The optional *object_type* keyword at the beginning of a layer mapping line applies to the *write_gds* and *read_gds* command.

tool_layer_number is the layer number in the database, an integer.

Feedback

tool_purpose is the purpose number in the database, an integer.

use_type is the usage type in the database, which is one of the following. The sealring_name in sealring_boundary[,sealring_name] is an NDM sealring object name. If it's not specified, it will map to keepout margin object type seal_ring. e.g. all *:*:sealring_boundary,SR1 136:1 ;map GDS layer 136:1 to NDM sealring object ;named SR1 all *:*:sealring_boundary,SR2 136:2 ;map GDS layer 136:2 to NDM sealring object ;named SR2 all *:*:sealring_boundary 136:3 ;map GDS layer 136:3 to design library keepout margin object ;type seal_ring

"assembly_die_boundary" maps to keepout margin object type assembly_die. The custom[,label] is a custom manufacturing shape with specified label name. If label is not specified with "custom" use_type, an error is reported by the tool. e.g. all *:*:custom,DIE1 136:1 ;map GDS layer 136:1 to NDM custom object ;labeled DIE1 all *:*:custom,DIE2 136:2 ;map GDS layer 136:2 to NDM custom object ;labeled DIE2

```
power
  ground
  clock
  signal
  boundary
  hard_placement_blockage
  soft_placement_blockage
  routing_blockage
  area_fill
  track
  route_guide,single_row_via_ladder_pattern_must_join_allowed
  routing_blockage,is_allow_metal_fill_only
  sealring_boundary[,sealring_name]
  assembly_die_boundary
  stitching_zone
  routing_blockage,reserve_for_top_level_routing
  ring
  custom[,label]
```

mask_type is the mask type of the shape in a multiple-patterning technology. For a metal layer, the following mask types are supported:

```
mask_one
  mask_two
  mask_three
  same_mask
```

For a VIA cut layer, the following additional mask types are supported:

```
MASK_FOUR
  MASK_FIVE
  MASK_SIX
  ...
  MASK_FIFTEEN
```

Feedback

gdsii_layer_num is the layer number of the geometry or TEXT in the GDSII file, an integer.

gdsii_data_type is the data type number of the geometry or TEXT in the GDSII file, an integer.

Block Mapping File

You can optionally provide a block mapping file to specify whether to add, ignore, overwrite, retain or merge specific blocks, identified by name; and you can specify how each block is mapped into the library with respect to block type, site name, and boundary.

This is the mapping file format:

```
; C++ style single line comment
block_name[:rw_type[,flatten[:levels]]] \\
  [block_type] [-fixed_mask] [-site_name site_name]
 [-centerline_boundary]
```

For example,

```
; This is my block mapping file
BlockA:ignore      ; ignores BlockA (does not write it to the library)
BlockB:overwrite   ; BlockB overwrites any existing block named BlockB
BlockC:update      ; Merges BlockC data into any existing block named
 BlockC
BlockD:add,flatten        ; Flattens BlockD by one level
BlockE:add,flatten:2      ; Flattens BlockE by two levels
BlockF:flatten:2          ; Flattens BlockF by two levels (implicit
 "add")
BlockG:overwrite,flatten  ; Flattens BlockG and overwrites existing
 BlockG
BlockH:retain macro       ; creates the instance of this BlockH but
                          ; doesn't define the reference lib-cell
```

In each line, any text after a semicolon ";" is a comment.

Each line consists of the following syntax items:

- *block_name*: The name of the block. It can be a regular expression to specify a range of block names, for example, containing an asterisk "*" wildcard character.
- *rw_type*: Specifies how to read the block into the library:
  - *add*: Reads the block as a new block (default behavior)
  - *ignore*: Ignores the block (does not read it to the library)
  - *overwrite*: Reads the block and overwrites any existing block with the same name
  - *update*: Reads the block and merges the data with any existing block with the same name
  - *retain*: Retain the instance but not create the reference lib-cell.

Feedback

- *,flatten*[:*levels*] : Flattens the hierarchy of all the instances of the named block, one level deep by default. To flatten more than one level, specify the number of levels after a colon:

  ```
  BlockE:add,flatten:2
  BlockF:flatten:2
  ```

  In the latter example, the "add" *rw_type* is implicit because it is the default action.

- *block_type*: The type of the block written into the library:

  ```
  abstract
      analog
      black_box
      corner
      cover
      diode
      end_cap
      feedthrough
      fill
      filler
      flip_chip_driver
      flip_chip_pad
      lib_cell
      macro
      module
      pad
      pad_spacer
      well_tap
      tsv
      package
      pcb
      rdl_fanout
  ```

  If design type is not specified for a cell in block mapping file, this command will set leaf cell's design type as standard cell (lib_cell), others as module.

- *-fixed_mask*: Identifies the block as having fixed masks in a multiple-patterning technology by setting the block's is_mask_shiftable attribute to false.

- *-site_name site_name*: Identifies the site name associated with the library cell.

- *-centerline_boundary*: Creates the block boundary by joining the line segments that pass through the centers of the pins in the design view. By default, the bounding box of the cell is used as the block boundary.

Examples

The following example reads the design.gds GDSII file and stores the data in the library named testLib. If the library does not already exist, the command creates it.

Feedback

```
prompt> read_gds -library testLib design.gds
1
```

---

read_ivm

Reads via variation file(.ivm) for current desgin.

Syntax

status *read_ivm*

```
file_name
[-corners corners]
```

Data Types

```
file_name string
corners   list
```

Arguments

file_name

Specifies the via variation file name to read.

-corners *corners*

Specifies the list of corners for which to apply the extraction options. If corners are not specified then the ivm file will be applied to all corners.

Description

This command reads .ivm file for via variation analysis for the current design.

Examples

The following example reads new.ivm file for specified two corners.

Feedback

```
prompt> read_ivm new.ivm -corners
 {FuncMode_max.SS.081v.125c_FuncCmax.corner
 FuncMode_min.FF.099v.125c_FuncCmax.corner}
```

See Also

---

read_lib_package

Restores the libraries and application option settings from a library package file that is previously created by the *write_lib_package* command.

Syntax

status *read_lib_package*

```
packed_lib_file_name
[-destination directory_name]
[-overwrite]
[-replay]
```

Data Types

```
packed_lib_file_name     string
directory_name           string
```

Arguments

packed_lib_file_name

Specifies the name of the library package file.

-destination *directory_name*

Specifies the name of the destination directory where the library are unpacked. The default is the current directory.

-overwrite

Overwrites any identically named library at the destination directory. As an identically named library at the destination directory causes an error, and prevents the library from being restored from the package file.

Feedback

`-replay`

Skips unpack step provided an identically named unpacked library is already present at the destination. All the environment settings are sourced on the already present on-disk library. This option is mutually exclusive with *-overwrite* option. If the option is provided and no on-disk library present, then the *read_lib_package* command follows its normal flow.

Description

This command restores the design library and reference libraries from a library package file previously created by the *write_lib_package* command. After unpacking the library, the command opens the library and sets the current design to match the library that was packed. It also sets the application options and Tcl variables to match the state of the library at the time of packing. Some application Tcl variables are not restored. List of those Tcl variable is present in NDMUI-1040.

After running the *read_lib_package* command, ensure that you have saved all the libraries and blocks on to disk by running *save_lib -all* command so that all the data from the package persists on disk.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example unpacks the library package file mylib.pack. It restores the design library to the current directory and the reference libraries to a directory called reflibs under the directory of the restored design library.

```
prompt> read_lib_package mylib.pack
1
```

The following example unpacks the library package file mylib.pack and restores the design library to the directory one level above the current directory. If a design library of the same name already exists at the destination, the command overwrites the existing library.

```
prompt> read_lib_package -destination .. -overwrite mylib.pack
1
```

See Also

- write_lib_package

---

read_name_map

Reads a name map file for the current design.

Feedback

Syntax

string *read_name_map*

name_map_file

Data Types

name_map_file string

Arguments

name_map_file

Specifies the name of the input name map file.

Description

The *read_name_map* command reads the name map data from the specified name map file for the current block.

The name mapping file is a Tcl script containing Tcl built-in commands and two Synopsys commands: *set_query_rules*, which defines renaming rules for rule-based query, and *define_name_maps*, which defines the name mapping for specific objects. The file is provided information only; you should not edit or modify it.

The following is an example of a name mapping file:

```
# Query Rules
set_query_rules hierarchical_separator {/ _} bus_notation {[] __}

# Tcl built-in: local variables
set hier_1  A/B/C/D
set hier_2  A_B/B2/this/is/a/long/path

# Explicit name maps
define_name_maps \\
     -application golden_upf \\
     -design_name design \\
     -columns {class pattern options names} \\
     [list cell $hier_1/A_reg [list leaf]        [list $hier_2/ger_A]
     ] \\
     [list cell A/B/X*_reg    [list nocase leaf] [list A_B/zar_reg
 A_B/Y_reg3]]

# cleanup
unset hier_1
unset hier_2
```

Feedback

Examples

The following example reads a name map file:

```
prompt> read_name_map top.nmf
```

See Also

- write_name_map
- load_upf
- set_query_rules

---

read_net_estimation_rules

Reads an XML document that contains net estimation rules. This command can be used to re-create the net estimation rules previously saved with the *write_net_estimation_rules* command.

Syntax

int *read_net_estimation_rules*

```
-filename xml_filename
[-cell cell]
```

Data Types

```
xml_filename  string
cell                collection
```

Arguments

`-filename` *xml_filename*

Specifies the name of the XML document to read that contains net estimation rule data. This command attempts to apply any valid rules and parameters found in the document to the current net estimation rules. The command reports any errors detected while reading the XML document.

`-cell` *cell*

Specifies the physical cell into which to read the net estimation rule.

By default, rules are read back into the cell in which they were created (the cell attribute in the XML file). If the save file does not specify a cell, they are read into the current block. -cell overrides any saved cell in the XML file.

Feedback

Description

This command reads an XML document containing net estimation rule data. The XML document can be written by the *write_net_estimation_rules* command or created manually.

NET ESTIMATION RULES AND HIERARCHY

Net estimation rules can be created in any physical block at any level of the hierarchy and multiple blocks can have different rules with the same name. However, rules are often stored/retrieved by name, and doing this can cause confusion as to which rule is being used by a given command. Generally, the "current" (top) block's list of rules is searched by commands such as *estimate_timing*. This means that if you define rule R1 in "top" and rule R1 in block "B1", if you make block B1 the current block, commands will use B1's R1. When you go back to top, top's R1 is used. To avoid confusion, use globally unique rule names and define them at the top - they will be propagated to child blocks during distributed commands as necessary. Rules in child blocks that have the same name as rules in top may also be overwritten during distributed commands.

Examples

The following example creates one non-default rule, writes out the rule as an XML document, and saves the file to rules.xml.

```
prompt> set_net_estimation_rule -parameter register_spacing -value 20
 myrule
prompt> write_net_estimation_rules -script rules.xml -format xml
1
```

The following example reads an existing net estimation rule document called rules.xml written out in the previous example.

```
prompt> read_net_estimation_rules -filename rules.xml
1
```

trace_option          string
port_names            string
trace_limit           integer
net_property_value    string
cell_property_value   string
pin_property_value    string
via_property_value    string
ascii_file_name       string
file_names            list of strings
layers                list of strings
```

Arguments

`-library lib_name`

Specifies the name of a library (or a single-library collection) in which to add the OASIS data. If the library already exists, the OASIS data is added to that library. Otherwise, the command creates a new library with the specified name and

Feedback

adds the OASIS data to that library. By default, the command uses the library name field of the OASIS file.

`-layer_map` *`layer_map_file_name`*

Specifies a layer mapping file that customizes the translation of layer, data type, and purpose between the OASIS file and tool's data model. For details, see "Layer Mapping File" in the DESCRIPTION section.

`-block_map` *`block_map_file_name`*

Specifies the name of a block mapping file. The file specifies whether to add, ignore, overwrite, retain or merge specific blocks; and how each block is mapped into the database with respect to block type, site name, and centerline boundary. For details, see "Block Mapping File" in the DESCRIPTION section.

`-merge_action add | overwrite | update | ignore`

Specifies how to handle conflicts between identically named blocks:

- *add*: Adds a new block to the database using a new name (the default)
- *overwrite*: Replaces any existing block with the same name
- *update*: Merges the geometries of the block into the existing block in the database
- *ignore*: Ignores the new OASIS block and keeps the exiting block

`-keep_text`

Specifies whether to keep text boxes after the pins are identified. This option determines whether text shapes are kept or removed after connectivity tracing. The default is to remove the text boxes. The text itself is always kept.

`-trace_option` *`trace_option`*

Specifies the conditions for performing connectivity tracing, in which the tool traces overlapping geometries to determine the extent of each net. These are the possible settings:

- *none*: Prevents connectivity tracing
- *pins_only*: Identifies pin shapes that directly overlap the text shapes, but does not propagate the pin information to the shapes that do not directly overlap with the text shapes, even when they overlap the identified pin shapes
- *all_layers*: Propagates the connectivity across all layers

Feedback

- *same_layer*: Traces the connectivity only on the same layer
- *auto*: Traces the connectivity using the *same_layer* or *pins_only* setting, depending on the object type:

```
Object type       Trace option setting used in "auto" mode

abstract:         pins_only
analog:           pins_only
black_box:        pins_only
corner:           same_layer
cover:            same_layer
diode:            same_layer
end_cap:          same_layer
feedthrough:      same_layer
fill:             same_layer
filler:           same_layer
flip_chip_driver: same_layer
flip_chip_pad:    same_layer
lib_cell:         same_layer
macro:            pins_only
module:           pins_only
pad:              same_layer
pad_spacer:       same_layer
well_tap:         same_layer
package:          pins_only
pcb:              pins_only
rdl_fanout:       pins_only
```

The default trace option setting is *auto*.

`-trace_connectivity_limit` *trace_limit*

Specifies the maximum number of geometries to be traced for connectivity. If the number of geometries traced exceeds this limit, then tracing falls back to same-layer-tracing only. By default, there is no limit.

`-trace_all_layers_for` *port_names*

Specified ports will be traced for all the layers. It has lower priority than the *-ignore_connectivity_layers* command option setting.

`-net_property` *net_property_value*

Extracts the net name as a property attribute with the specified attribute number or property name in the OASIS stream. By default, no net names are extracted from OASIS property attributes.

Feedback

`-cell_property` *`cell_property_value`*

Extracts the instance name as a property attribute with the specified attribute number or property name in the OASIS stream. By default, no instance names are extracted from OASIS property attributes.

`-pin_property` *`pin_property_value`*

Extracts the pin name as a property attribute with the specified attribute number or property name in the OASIS stream. By default, no pin names are extracted from OASIS property attributes.

`-via_property` *`via_property_value`*

Extracts the via and via matrix property with the specified attribute number or property name in the OASIS stream. By default, no via or via matrix property is extracted from OASIS file.

`-ascii` *`ascii_file_name`*

Writes the OASIS data to the specified text file in ASCII format. By default, the command does not write out the OASIS data.

`-verbose`

Reports additional information on the special handling of data related to the layer, data type, or block mapping.

`-centerline_boundary`

Creates the boundary for each block by joining line segments that pass through the centers of the pins in the design view of the block. By default, the boundary is the bounding box of block.

`-mask_fixed`

Marks the library as not mask shiftable by setting the library's is_mask_shiftable attribute to false in the database. This prevents mask shifting from being performed in the library in a double-patterning technology.

`-layer_map_format icc2 | icc_default | icc_extended`

Specifies the format of the layer mapping file. This option allows the command to accept an IC Compiler layer mapping file. These are the allowed settings:

- *icc_default*: IC Compiler default layer mode, system layers 188-255
- *icc_extended*: IC Compiler extended layer mode, system layers 4001-4095
- *icc2*: IC Compiler II layer mapping file format (default)

Feedback

`-read_always true | false`

Specifies whether the command always reads in layers from the OASIS file, even when those layers do not already exist in the technology data of the library:

- *true*: The command reads in layers that do not already exist in the library by creating new layers in the library's technology data.
- *false* (the default): If an OASIS layer does not already exist in the technology data of the library, the command reports an error and stops working by default. However, you can allow processing to continue by using the *-ignore_missing_layers* option.

A "read_always" entry in the layer mapping file for a particular layer has higher priority than the *-read_always* command option setting.

`-ignore_missing_layers`

Specifies that the command will continue to work even when an incoming OASIS layer is not present in the technology data of the library. In that case, the command ignores the OASIS layer and issues a warning message.

`-ignore_connectivity_layers` *`layers`*

Specifies the layers on which shapes are ignored while tracing connectivity. If there is text on the specified layer, it is given higher priority. The terminal is created on the layer.

`-disable_link`

Disable the link. It is recommended to use this option when only layout view is needed. By default, *read_oasis* always does the link.

`-mapped_layers_only`

Specifies that the command reads only the objects for which a mapping is defined in the layer mapping file, from the OASIS layer-datatype pair of the object to a layer-datatype pair in the database. If such a mapping does not exist, the command reports a warning and ignores the object. If the object is on a missing layer and the *-ignore_missing_layers* option is used, the object is ignored and no warning is issued.

`-top_design_name` *`top_design_name`*

Specifies to trace only the top design, even several top designs are available from an OASIS file.

`-trace_top_only`

Specifies to trace only a top design. Its reference designs won't be traced anymore. Without setting this option, all the top designs and their reference designs are to be traced.

Feedback

`-top_design_type` *`design_type`*

Specifies the design type of the top design. The valid values for this option are *abstract*,*analog*, *black_box*, *corner*, *cover*, *diode*,*end_cap*, *feedthrough*, *fill*, *filler*, *flip_chip_driver*, *flip_chip_pad*, *lib_cell*, *macro*, *module*, *pad*, *pad_spacer*, *well_tap*, *package*, *die*, and *interposer*.

It is a shortcut for *-block_map* and overrides a rule specifed by *-block_map*. It is appropriate for a huge OASIS file with only a top design. It doesn't take effect when it's not set.

`-disable_force_link`

Specifies linker to first check if the design is linked and if it is, linker would do nothing. By default, linker even if it is linked already, and linker to examine each reference and bind it again, based on the current reference libraries.

This option need not to be set only reference libriaries have been set like by *set_ref_libs* before read_gds

`file_names`

Specifies the names of the OASIS input files.

Description

The *read_oasis* command reads one or more OASIS stream files into the library workspace and converts the data to NDM format for library preparation purposes. Each usage of the *read_oasis* command creates a new library unless the *-library* option specifies the name of an existing library.

The OASIS data does not define port type information. To prevent library preparation errors, you should set the port type mapping by using the *file.oasis.port_type_map* application option.

To find files that have relative pathnames, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path*. Files that have absolute pathnames are loaded without using the *search_path* variable. To determine the path to a particular file name, use the *which* command.

Layer Mapping File

By default, the *read_oasis* command maintains the original layer numbers of the OASIS files as it builds the library.

You can optionally provide a layer mapping file to specify the mapping of layers and data types between the OASIS layers and the database. You can use the same mapping file for both the *read_oasis* and *write_oasis* commands. This is the mapping file format:

```
; single line comment
[read_always { true | false [-mapped_only | -ignore_missing_layers ] } ]
```

Feedback

```
[blockage_as_zero_spacing {true|false}]
[cell_prop_attribute attribute_number]
[net_prop_attribute  attribute_number]
[pin_prop_attribute  attribute_number]
[via_prop_attribute  attribute_number]
[object_type] tool_layer_number[:tool_purpose][:use_type][:mask_type] \\
  oasis_layer_num[:oasis_data_type]
```

For example,

```
; This is my layer mapping file
                    ;
     84       92    ; ICC2 layer 84 = OASIS layer 92
                    ;
     59       69:3  ; ICC2 layer 59 = OASIS layer 69, data type 3
                    ;
     17:1    117:3  ; ICC2 layer 17, purpose 1 = OASIS layer 117, data
 type 3
                    ;
data 33:0:*:*  1:2  ; ICC2 data on layer 33, purpose 0, any use type,
                    ;  any mask type = OASIS layer 1, data type 2
text 33:0:*:*  1:4  ; ICC2 text on layer 33, purpose 0, any use type,
                    ;  any mask type = OASIS layer 1, data type 4
                    ;
; all other layers and data types match between ICC2 and OASIS
```

In each line, any text after a semicolon ";" is a comment.

The *read_always* statement determines how the *read_oasis* command handles differences between OASIS layers and database layers:

- *read_always true*: The command always reads in every layer. If the layer is not already present in the library's technology data, the command adds a new layer to the technology data.
- *read_always false*: If the layer does not already exist in the library's technology data, an error occurs and processing stops.
- *read_always false -ignore_missing_layers*: If the layer does not already exist in the library's technology data, the command ignores that layer, issues a warning, and continues processing.
- *read_always false -mapped_layer*: The command reads only the layers defined in the layer mapping file. If any incoming layer is not defined in the library's technology data, the command ignores that layer, issues a warning, and continues processing.

The *blockage_as_zero_spacing* statement determines how the *read_oasis* command interprets OASIS blockage layers, as either zero-spacing or design-rule-spacing guides. Use *blockage_as_zero_spacing true* for zero-spacing guides. The default is to interpret blockages as design-rule-spacing guides.

Feedback

The *cell_prop_attribute*, *net_prop_attribute*, *pin_prop_attribute*, and *via_prop_attribute* statements specify the property attribute numbers used for storing cell instance, net, pin names, and via attribute in the OASIS file. The specified value for the properties should be distinct while generating the OASIS file. For example, the statement "net_prop_attribute 5" causes the *write_oasis* command to write out net names of objects as property attribute 5 in the OASIS file. These statements in the layer mapping file have higher priority than the corresponding *write_oasis* command options, *-instance_property*, *-net_property*, *-pin_property*, *-via_matrix_property* and *-via_property*.

After you write an OASIS file with these properties, when you read the file back into the tool with the *read_oasis* command, the original cell names are restored, and the pins and nets are properly identified without the tool spending time on connectivity tracing.

Each field of the layer mapping line is separated by a colon ":". Each field can be an explicit value, an asterisk "*" wildcard character, or left blank. An asterisk or black space indicates any value.

A more specific rule priority than a more general rule. For example, the rule "5:3 8", has higher priority than "5 7". If conflicting rules are specified in different lines (for example, first "6:2 4" and then "6:2 7"), the last one in the file is used and the earlier one is ignored.

The optional *object_type* keyword at the beginning of a layer mapping line applies to the *write_oasis* and *read_oasis* command.

tool_layer_number is the layer number in the database, an integer.

tool_purpose is the purpose number in the database, an integer.

use_type is the usage type in the database, which is one of the following. The sealring_name in sealring_boundary[,sealring_name] is an NDM sealring object name. If it's not specified, it will map to keepout margin object type seal_ring. e.g. all *:*:sealring_boundary,SR1 136:1 ;map GDS layer 136:1 to NDM sealring object ;named SR1 all *:*:sealring_boundary,SR2 136:2 ;map GDS layer 136:2 to NDM sealring object ;named SR2 all *:*:sealring_boundary 136:3 ;map GDS layer 136:3 to design library keepout margin object ;type seal_ring

"assembly_die_boundary" maps to keepout margin object type assembly_die. The custom[,label] is a custom manufacturing shape with specified label name. If label is not specified with "custom" use_type, an error is reported by the tool. e.g. all *:*:custom,DIE1 136:1 ;map OASIS layer 136:1 to NDM custom object ;labeled DIE1 all *:*:custom,DIE2 136:2 ;map OASIS layer 136:2 to NDM custom object ;labeled DIE2

```
power
  ground
  clock
  signal
  boundary
  hard_placement_blockage
  soft_placement_blockage
```

Feedback

```
  routing_blockage
  area_fill
  track
  route_guide,single_row_via_ladder_pattern_must_join_allowed
  routing_blockage,is_allow_metal_fill_only
  sealring_boundary[,sealring_name]
  assembly_die_boundary
  stitching_zone
  routing_blockage,reserve_for_top_level_routing
  ring
  custom[,label]
```

mask_type is the mask type of the shape in a multiple-patterning technology. For a metal layer, the following mask types are supported:

```
mask_one
  mask_two
  mask_three
  same_mask
```

For a VIA cut layer, the following additional mask types are supported:

```
MASK_FOUR
  MASK_FIVE
  MASK_SIX
  ...
  MASK_FIFTEEN
```

oasis_layer_num is the layer number of the geometry or TEXT in the OASIS file, an integer.

oasis_data_type is the data type number of the geometry or TEXT in the OASIS file, an integer.

Block Mapping File

You can optionally provide a block mapping file to specify whether to add, ignore, overwrite, retain or merge specific blocks, identified by name; and you can specify how each block is mapped into the library with respect to block type, site name, and boundary.

This is the mapping file format:

```
; C++ style single line comment
block_name[:rw_type[,flatten[:levels]]] \\
  [block_type] [-fixed_mask] [-site_name site_name]
 [-centerline_boundary]
```

For example,

```
; This is my block mapping file
BlockA:ignore      ; ignores BlockA (does not write it to the library)
BlockB:overwrite   ; BlockB overwrites any existing block named BlockB
```

Feedback

```
BlockC:update      ; Merges BlockC data into any existing block named
 BlockC
BlockD:add,flatten        ; Flattens BlockD by one level
BlockE:add,flatten:2      ; Flattens BlockE by two levels
BlockF:flatten:2          ; Flattens BlockF by two levels (implicit
 "add")
BlockG:overwrite,flatten  ; Flattens BlockG and overwrites existing
 BlockG
BlockH:retain macro       ; creates the instance of this BlockH but
                          ; doesn't define the reference lib-cell
```

In each line, any text after a semicolon ";" is a comment.

Each line consists of the following syntax items:

- *block_name*: The name of the block. It can be a regular expression to specify a range of block names, for example, containing an asterisk "*" wildcard character.
- *rw_type*: Specifies how to read the block into the library:
  - *add*: Reads the block as a new block (default behavior)
  - *ignore*: Ignores the block (does not read it to the library)
  - *overwrite*: Reads the block and overwrites any existing block with the same name
  - *update*: Reads the block and merges the data with any existing block with the same name
  - *retain*: Retain the instance but not create the reference lib-cell.
- *,flatten*[:*levels*] : Flattens the hierarchy of all the instances of the named block, one level deep by default. To flatten more than one level, specify the number of levels after a colon:

  ```
  BlockE:add,flatten:2
  BlockF:flatten:2
  ```

  In the latter example, the "add" *rw_type* is implicit because it is the default action.
- *block_type*: The type of the block written into the library:

  ```
  abstract
      analog
      black_box
      corner
      cover
      diode
      end_cap
      feedthrough
      fill
      filler
      flip_chip_driver
  ```

Feedback

```
flip_chip_pad
lib_cell
macro
module
pad
pad_spacer
well_tap
tsv
package
pcb
rdl_fanout
```

If design type is not specified for a cell in block mapping file, this command will set leaf cell's design type as standard cell (lib_cell), others as module.

- *-fixed_mask*: Identifies the block as having fixed masks in a multiple-patterning technology by setting the block's is_mask_shiftable attribute to false.
- *-site_name site_name*: Identifies the site name associated with the library cell.
- *-centerline_boundary*: Creates the block boundary by joining the line segments that pass through the centers of the pins in the design view. By default, the bounding box of the cell is used as the block boundary.

Examples

The following example reads the design.oasis OASIS file and stores the data in the library named testLib. If the library does not already exist, the command creates it.

```
prompt> read_oasis -library testLib design.oasis
1
```

---

read_ocvm

Reads AOCV/POCV derating factor tables.

Feedback

Syntax

int *read_ocvm*

```
[-corners <list_of_corners>]
ocvm_file
```

Data Types

```
ocvm_file     string
```

Arguments

`-corners`

Indicates the list of corners for which the AOCV/POCV derate factors are to be applied. If this option is not provided, the corner associated with the current scenario is used.

ocvm_file

Specifies the name of the AOCV/POCV file.

Description

The *read_ocvm* command reads AOCV/POCV derate factor tables from a disk file. The tables are annotated onto one or more design objects. Allowed design object types are hierarchical cells, library cells and designs. The AOCV/POCV data is used to reduce pessimism and improve the accuracy of results. Set the app option *time.aocvm_enable_analysis* to enable AOCV analysis, and set the app option *time.pocvm_enable_analysis* to enable POCV analysis.

Note that a net inherits the AOCV/POCV derate set of a hierarchical cell (design) that fully contains the net. For example, for nets that cross the boundary between the top level and a block (with an associated AOCV/POCV table set), the lowest level hierarchical cell that fully contains the net is not the block. Therefore, the net derating comes from an AOCV/POCV table set that contains the block and fully encloses the net.

When applying AOCV/POCV tables on multiple object types that apply to an arc, the following priority, in decreasing order of precedence, is used to determine the table that applies to the arc:

1) Library cell table 2) Hierarchical cell table 3) Design table

Tables are processed in the order that they appear in the AOCV/POCV file. The last table of a specific type {object_type, rf_type, delay_type, derate_type} to be defined for an object in the file overwrites previous tables defined for the same object of the same type.

The *read_ocvm* command can read binary and compressed binary AOCV/POCV files created using the *write_binary_aocvm* command. No additional arguments are required to read binary or compressed binary AOCV/POCV files.

Feedback

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the *-corners* option.

Examples

The following example shows an AOCV derate file, test.aocvm, with a single table annotated on the design.

```
prompt> sh cat test.aocvm

version:        1.0

object_type:    design
rf_type:        rise
delay_type:     cell
derate_type:    late
object_spec:
voltage:        1.02
depth:          1 2 3
distance:       100 1000
table:          1.20 1.10 1.08
                1.22 1.15 1.11

prompt> read_ocvm test.aocvm
```

---

read_optimization_history

Read design optimization history from saved file.

Feedback

Syntax

```
status read_optimization_history
[-file file_name]
```

Description

This command restores the history of the optimization steps applied to the design.

See Also

- report_optimization_history

---

read_parasitic_tech

Reads in one or more parasitic model files in TLUPlus format or common nxtgrd file format.

Syntax

```
string read_parasitic_tech
-tlup tlup_files
[-layermap layer_map_file]
[-name name]
[-sanity_check none | basic | advanced]
[-fill_emulation true | false ]
```

Data Types

```
tlup_files      string
layer_map_file  string
name            string
```

Arguments

`-tlup tlup_files`

Specifies the names of one or more TLUPlus files or common nxtgrd file to read. This argument is required and you must provide at least one TLUPlus file name.

`-layermap layer_map_file`

Specifies the names of the layer map file between the technology file and the ITF file.

`-name name`

Specifies the name which identifies this model. If not specified, the base file name is used as the parasitic tech model name.

Feedback

`-sanity_check none | basic | advanced`

Disables or enables certain level of sanity check on TLUPlus file and layer mapping file. Default value is basic. Set value "none" to disable all sanity checks. Set value "advanced" to enable strict layer mapping file checks.

`-fill_emulation true | false`

Read TLUPlus file with or without fill emulation. Default value is false. Use this option for the common tech file only. Set value "false" to read TLUPlus file without fill emulation. Set value "true" to read TLUPlus file with fill emulation.

RC parasitic extraction recognizes the parasitic tech by model name. A different name implies a different parasitic tech.

Description

This command reads in parasitic model data files. After the data is read in, it is stored in current library and the TLUPlus files or common tech file are no longer referenced. The data and TLUPlus files name are saved to disk along with other library data when the *save_lib* command is issued. The parasitic data is used in RC parasitic extraction, delay calculation, net estimations, and other applications.

The layer map file maps the technology file layer name to Interconnect Technology Format (ITF) layer name. The "conducting_layers" and "via_layers" keywords are used to identify the layer properties. Lines starting with * or # are comments in the layer mapping file. If there is no layer map file specified, the ITF layer name is treated the same as the technology layer name.

The following is an example of the layer map file.

```
*****Technology_maskName VS ITF_layerName*****
conducting_layers
poly      fpoly
metal1    metal1
metal2    metal2
metal3    metal3
metal4    metal4
metal5    metal5
metal6    metal6
metal7    metal7
via_layers
polyCont  polyCont
via1      via1
via2      via2
via3      via3
via4      via4
via5      via5
via6      via6
```

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example reads in the file.tlup TLUPlus file.

```
prompt> read_parasitic_tech -tlup file.tlup -layermap file.layermap \\
   -name critical_worst_param_1
```

The following example reads in the file.nxtgrd nxtgrd file.

```
prompt> read_parasitic_tech -tlup file.nxtgrd -layermap file.layermap \\
   -name critical_worst_param_1
```

---

read_parasitics

Reads parasitics from SPEF files or GPD path, GPD attachment in ndm design for current design and sub designs.

Syntax

status *read_parasitics*

```
[-corner_spef {corners spef_file [corner_type]}\
[-gpd gdp_path]
[-gpd_attach]
```

Feedback

```
[-block block_name]
[-validate]
```

Data Types

```
corners       list
spef_file     string
corner_type   string
block_name    string
gpd_path string
```

Arguments

`-corner_spef {corners spef_file [corner_type]}`

Specifies the SPEF files associated with the constraint corners.

You can specify this option multiple times. If corners share the same SPEF file, you can specify them in the same *-corner_spef* option by listing the corner names. Otherwise, you must specify the files in different *-corner_spef* options. See the first example in the EXAMPLES section.

The valid values for the *corner_type* argument are *early* and *late*. If you do not specify the *corner_type* argument, the SPEF file is for both early and late.

The .spef_scenario file generated by the *write_parasitics* command has the association of corner scenarios with the SPEF files.

`-gpd gpd_path`

Specifies the gpd path for RC annotation. Users need to make sure the input GPD which have the matched corners with corners defined in the working block. Otherwise, read parasitics from GPD would be failed with error message.

`-gpd_attach`

read RC from gpd attached in the working ndm design. If ndm design does not have gpd attached, read parasitics from GPD attachment would be failed with error message.

`-block block_name`

Specifies the block name associated with the specified SPEF files. Use this option if the SPEF files are for a subblock.

If the SPEF files are for a subblock, the corners specified in the *-corner_spef* options should be corners defined for the top-level block.

By default, the SPEF files are for the top-level block.

`-validate`

Execute validation.

Feedback

Description

This command reads parasitics for the current design and sub designs from the SPEF files, or GPD path, GPD attachent. *read_parasitics* is the block level command. You need to specify one *read_parasitics* command for each block for hierarchical design. The *read_parasitics* command would annotate RC for the nets reading from SPEF files,or GPD path, GPD attachment. The nets in the design not annotated would be estimated when executing the *report_timing* command after running *read_parasitics*.

Examples

The following example reads SPEF files for the current block, which has multiple constraint corners. Two constraint corners of the total eight corners share one SPEF file.

```
prompt> read_parasitics \\
   -corner_spef {{FuncMode_max.SS.081v.125c_FuncCmax.corner \\
      FuncMode_min.FF.099v.125c_FuncCmax.corner} dr_cc_max_125.spef} \\
   -corner_spef {{FuncMode_min.FF.099v.m40c_FuncCmax.corner \\
      FuncMode_max.FF.081v.m40c_FuncCmax.corner} dr_cc_max_m40.spef} \\
   -corner_spef {{FuncMode_max.SS.081v.125c_FuncCmin.corner \\
      FuncMode_min.FF.099v.125c_FuncCmin.corner} dr_cc_min_125.spef}
   -corner_spef {{FuncMode_min.FF.099v.m40c_FuncCmin.corner \\
      FuncMode_min.FF.081v.m40c_FuncCmin.corner} dr_cc_min_m40.spef}
```

The following example reads SPEF files for a hierarchical design that has one subblock. The first *read_parasitics* command is for the top-level block. The second *read_parasitics* command is for the subblock.

```
prompt> read_parasitics -corner_spef {s1.corner input/top.spef}
prompt> read_parasitics -block {rm2000_l2data_spr4096x288_bistw} \\
   -corner_spef {s1.corner input/block.spef}
```

The following example reads GPD path for a current block

```
prompt> read_parasitics -gpd input/top.gpd fP
```

The following example reads GPD attached in current ndm block for a current block

```
prompt> read_parasitics -gpd_attach fP
```

---

read_physical_rules

Imports library/cell level abstract physical rules and attributes through a PRF file to target the library and its cells.

Syntax

int *read_physical_rules*

```
file_name
[-include include_list]
[-library lib]
```

Data Types

```
file_name     string
include_list  list of string
lib           string
```

Arguments

file_name

Specifies the file name to be read in. This is a required option.

-include *include_list*

Specifies which rules are imported from the input file.

- *library*: Imports library level rules.
- *cell*: Imports cell/pin level rules and attributes.
- *instructions*: Imports stream in instructions as corresponding application options. This option is available only in Library Manager.
- *site*: Imports site and row_pattern and track_pattern under these two groups.
- *layer*: Imports layer definition under library level.
- *pin_attr*: Imports pin level attributes such as "direction","port_type", "pg_type" and "is_secondary_pg". This option can only work together with the "cell".
- *routing_blockage*: Imports routing_blockage definition. This option can only work together with the "cell".
- *density*: Imports density definition under library level.

Feedback

- *antenna*: Imports antenna definition under library level.
- *all*: Imports all rules and attributes.

The default in Library Compiler, Library Manager, and IC Compiler II is *{all}*.

`-library` *lib*

Specifies the target library to import the rules and attributes. This option is only available in IC Compiler II. If this option is not specified, the target library is found by the library name in the PRF file, or in the current library if it is not found in the PRF file.

In library manager, it is always the current workspace library. In Library Compiler, it is always the current physical library.

Description

This command reads in abstract physical rules and attributes from the input file to the target library and all its cells. In Library Manager, the file must be read in before running the *check_workspace* command, as cell data will be saved only at that time. In IC Compiler II, the file can be read to runtime reference libraries by specifying the *-library* option.

Examples

The following example reads in all rules from the in.prf file to the current library and all its cells.

```
prompt> read_physical_rules in.prf
2
```

The following example reads in instructions a cell attributes/rules from the in.prf file the to current library.

```
prompt> read_physical_rules in.prf -include {cell instructions}
2
```

The following example reads in cell level rules from the in.prf file to 'libA'.

```
prompt> read_physical_rules in.prf -include cell -library libA
2
```

See Also

- write_physical_rules
- remove_physical_rules

Feedback

read_pin_constraints

Reads pin constraints from the specified file and applies them to the current design.

Syntax

status *read_pin_constraints*

```
[-file_name file_name]
```

Data Types

```
file_name     string
```

Arguments

`-file_name` *name*

Specifies the file name that contains the pin constraints. The constraints are used by the router and pin placer.

Description

This command reads a file which contains pin and feedthrough constraints. The pin constraint file contains multiple sections that contain different types of constraints for the router and pin placer. Four sections are supported: topological map, physical pin constraints, pin spacing control, block pin constraints. Pin-based physical pin constraints supports multilevel physical hierarchy (MPH).

This command stores the pin constraints in the database. The constraints are treated the same as constraints that are set with other Tcl commands. You can use the *report_individual_pin_constraints* and *remove_individual_pin_constraints* commands to report and remove pin constraints.

The *set_editability* command can enable or disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the *set_editability* command.

Each section begins with a section header. Supported section headers are "start topological map", "start feedthrough control", "start physical pin constraints", "start pin spacing control", "start block pin constraints;". Each section ends with a section footer and a semicolon (;). The section footer corresponds to the section header and begins with the "end" keyword, for example "end topological map;". The constraint file specifies how nets should be routed through blocks in routing stage and how pin should be placed during pin placement.

Empty lines or lines with only white spaces are ignored. Leading or trailing white spaces are ignored. Lines that begin with comment character (#) are comments and are ignored.

Feedback

Curly brackets ({}) are used to separate different constraints and objects. A semicolon (;) separates different records. If there is more than one object following a constraint keyword, you must use curly brackets. In the following example, the first layer constraint is incorrect because the layer names are not surrounded by curly brackets. The second constraint shows the correct syntax.

```
{{cell A} {layers M2 M4}}  # incorrect
 {{cell A} {layers {M2 M4}} # correct
```

Topological Map

The topological map section contains routing topologies for different nets in the design. Add constraints to this section to specify how nets should be routed through blocks during pin placement.

Each record contains one or more net or bundle names, followed by pairs of linked objects. Use curly brackets to specify more than one net name. The objects can be block cell, top-level port or any cell instance pin. The pin can be a macro pin or standard cell pin, but cannot be the pin on physical block. Note that ports and pins cannot be specified for bundles. In following example, a net connects to cell_A, Cell_C, and Cell_E, you can force the routing to go through Cell_B to connect Cell_A and Cell_C as follows:

```
start topological map;
{Nets Net_A}
  {{{Cell Cell_A} {Cell Cell_B}}
   {{Cell Cell_B} {Cell Cell_C}}
   {{Cell Cell_A} {Cell Cell_E}}};
end topological map;
```

The following example forces routing to pass through Cell_B to connect top-level port A with a macro or standard cell pin C/a if Net_A does not connect to Cell_B:

```
start topological map;
{Nets Net_A}
  {{{Port A} {Cell Cell_B}}
   {{Cell Cell_B} {Pins C/a}}};
end topological map;
```

When you have a set of nets with the same routing patterns, you can describe them as a group of nets within curly brackets separated by spaces. In addition, you can use "*" as a wildcard to specify a set of nets, such as a bus. Note that when a set of nets are specified, you cannot use top-level ports or pins to describe the connectivity.

```
start topological map;
{Nets {Net_A Net_B DataIn*}}
  {{{Cell Cell_A} {Cell Cell_B}}
   {{Cell Cell_B} {Cell Cell_C}}};
end topological map;
```

Feedback

For block objects, you can specify side, offset, and layer constraints for the block pins. The side specifies the side number for a block instance where the pins are inserted. The side number is a positive integer that starts from 1. Given any block instance with a rectangular or rectilinear shape, the leftmost edge is side number 1. If there are multiple leftmost edges, then edge 1 is the lowest leftmost edge. The sides are numbered in consecutive order proceeded clockwise around the shape. The shape here referring to block instance's shape, not the reference block's shape.

The offset specifies the distance in microns or percentage from the starting point of a specific edge to the routing cross-point (or the block pin's center location) on that edge in clockwise direction. To specify a percentage, append a '%' character to the end of the float value. Percentage can be a value from -100 to 100 only. The starting point is also following the clockwise fashion. For instance, for a bottom horizontal edge, the starting point is the right vertex of the edge as it is counted in clockwise and bottom edge's starting point is right point vertex. Since the offset is specific on an edge, you must specify the side information with your offset. The edge here is referring to the edge on block instance, not the reference block.The topological constraints not support negative offset value.

The layer constraint specifies the metal layers to use for the pins.

The following example shows one net record in the topological map section that contains side, offset, and layers of the pins. The routing connects Cell_A through side 1 at offset 20.18 on layer M2 to Cell_B through side 3 at offset 40.28 on layer M4. The routing also connects Cell_B through side 1 at offset 30.28 on layer M4 to Cell_C through side 3 at offset 15.88 on layer M2.

```
start topological map;
{Nets Net_A}
   {{{Cell Cell_A} {sides 1}
     {offset 20.18} {layers M2}}
    {{Cell Cell_B} {sides 3}
     {offset 40.28} {layers M4}}}

   {{{Cell Cell_B} {sides 1}
     {offset 30.28} {layers M4}}
    {{Cell Cell_C} {sides 3}
     {offset 15.88} {layers M2}}};
end topological map;
```

The following example shows one net record in the topological map section that contains side, offset, and layers of the pins. The routing connects Cell_A through side 1 at offset 20.18% on layer M2 to Cell_B through side 3 at offset 40.28% on layer M4. The routing also connects Cell_B through side 1 at offset 30.28% on layer M4 to Cell_C through side 3 at offset 15.88% on layer M2.

```
start topological map;
{Nets Net_A}
   {{{Cell Cell_A} {sides 1}
     {offset 20.18%} {layers M2}}
```

Feedback

```
     {{Cell Cell_B} {sides 3}
      {offset 40.28%} {layers M4}}}

   {{{Cell Cell_B} {sides 1}
     {offset 30.28%} {layers M4}}
     {{Cell Cell_C} {sides 3}
      {offset 15.88%} {layers M2}}};
end topological map;
```

In addition, for block objects, you can specify routing cross-point's location range (or block pin's location range) on a side. Range can be distance or percentage. To specify a percentage, append a '%' character to the end of the float value. Percentage can be a value from -100 to 100 only. The location range is specified with a pair of numbers within {}.

In following example, the routing routes from Cell_A through side 2 with location range between 10 micron offset and 20 micron offset when connecting to Cell_B, and routing routes through Cell_B's side 4 with location range between 10 micron offset and 20 micron offset.

```
start topological map;
{Nets Net_A}
   {{Cell Cell_A} {sides 2}
     {offset {10 20}}}
   {{Cell Cell_B} {sides 4}
     {offset {10 20}}};
end topological map;
```

In following example, the routing routes from Cell_A through side 2 with location range between 10% offset and 20% offset when connecting to Cell_B, and routing routes through Cell_B's side 4 with location range between 10% offset and 20% offset.

```
start topological map;
{Nets Net_A}
   {{Cell Cell_A} {sides 2}
     {offset {10% 20%}}}
   {{Cell Cell_B} {sides 4}
     {offset {10% 20%}}};
end topological map;
```

For bundle-based topological constraints, the wildcard character (*) is not supported. For instance, you cannot specify a wildcard character for bundles, ports or pins as the bundle is a group of nets. In this context, the wildcard character for bundles, ports or pins can be confusing.

For a very complicated routing topology which involves multiple enters or exits on same block instance, the tool might not be able to generate routing topology that you intend to. In this case, it is recommended to start from the driver to define the routing topology. In the following example, a routing topology started from driver block A and goes to block B with side 1/offset 20, and then goes from block B to load block C. On the separated routing

Feedback

path on same net, the routing branch out from driver block A and goes to block B again and then goes to load block D. With different offset(40) on the same side(1) of block B, the topological constraints can be specified in following ways:

```
start topological map;
{Nets Net_E}
   {{Cell A} {{Cell B} {sides 1}{offset 20}}}
   {{{Cell B} {sides 3}{offset 40}} {Cell C}}
   {{Cell A} {{Cell B} {sides 1}{offset 40}}}
   {{{Cell B} {sides 3}{offset 20}} {Cell D}}
end topological map;
```

When there are multiple enters or exits on block B to avoid ambiguity, it is recommended to define the topology starting from driver. Also the physical constraints (side or offset or offset range} can be used to help resolve the ambiguity.

Feedthrough Control

The feedthrough control section enables or disables feedthroughs for specific nets and blocks. Each record begins with the Nets keyword and contains one or more net names within curly brackets. The net names are followed by "Feedthrough" or "NoFeedthrough" keywords, followed by block cells within curly brackets.

The following rules are used when applying the feedthrough control:

- Later statements override earlier statements for the same nets.
- The Feedthrough and NoFeedthrough keywords specify whether feedthroughs are allowed or not by default, for either specified block cells or for the entire design. If block cells are specified, all other blocks cells assume the opposite feedthrough constraint value. Therefore, only one Feedthrough or NoFeedthrough constraint line is required per specification, there is no need to specify both the Feedthrough and NoFeedthrough keywords in a single feedthrough specification.
- Topological map constraints can overrule feedthrough control statements. For example, the following topological map constraint forces a feedthrough on block B, regardless of whether feedthroughs are allowed on B.

  ```
  {{{cell A} {cell B}} {{cell B} {cell C}}}
  ```

The following example enables feedthroughs for net Xecutng_Instrn[0] on blocks I_ALU, I_REG_FILE and I_STACK_TOP.

```
start feedthrough control;
{Nets Xecutng_Instrn[0]}
  {Feedthrough {I_ALU I_REG_FILE I_STACK_TOP}};
end feedthrough control;
```

The following example prevents feedthroughs for net Xecutng_Instrn[0] on blocks I_ALU, I_REG_FILE and I_STACK_TOP.

Feedback

```
start feedthrough control;
{Nets Xecutng_Instrn[0]}
  {NoFeedthrough I_ALU I_REG_FILE I_STACK_TOP};
end feedthrough control;
```

A single Feedthrough or NoFeedthrough statement completely specifies the allowed feedthrough modules for the net. Feedthrough statements are not cumulative. If multiple feedthrough statements exist for the same net, the latest feedthrough statement take over the previous statement. This rule simplifies the organization of the feedthrough file and prevents complex interactions between feedthrough statements.

Feedthrough and NoFeedthrough statements override the default feedthrough permission set by the *create_block_pin_constraint -allow_feedthroughs true|false* command for the specified nets. However, feedthrough allows or disallows set by *set_individual_pin_constraints -allow_feedthroughs true|false* command for individual net overrules the feedthrough or NoFeedthrough statements.

The statement "{ Feedthrough A B }" does not force the creation of feedthroughs on A and B. Instead, the statement allows feedthroughs on blocks A and B, while restricting feedthroughs on all other blocks. To force a specific feedthrough path, you must use the pairwise statements described later.

If there are feedthrough constraint conflicts between topological map constraint and previous feedthrough constraints, the feedthrough constraints from constraint file take priority. If there are conflicts between feedthrough constraints and topological map constraints, topological map constraints take priority.

Physical Pin Constraints

The physical pin constraints section specifies physical pin constraints for individual nets, pins or ports. Supported keywords are: net, pins, reference, sides, layers, offset, order, start, end, off_edge, location, width and length.

The syntax for most supported constraint keywords (sides, layers, width, length, and so on) is the same as in the command *set_individual_pin_constraints*. See the related man pages for more details. For offset, *read_pin_constraints* can take a number as well as a range, which includes a startpoint and an endpoint.

Each record in the physical pin constraints section is a set of keywords with values enclosed by curly brackets and ended by a semicolon. The first element in the record can be a top-level net or a port for a reference block. If the record is a port object, the block is expected to follow with reference block's name associated with the port.

The physical pin constraints section also supports order for a collection of pins or ports, which is not very convenient by using command *set_individual_pin_constraints*. To set the order for a collection of pins or ports, it must specify the required edge. And it is also a good practice to specify the range by using *start* and *end*. Otherwise, it means the whole edge. In the most simple case as shown in the following example, the distance between

Feedback

the adjacent order constrained pins or ports is roughly equal to the range divided by the number of order constrained pins or ports. Therefore, if there is a big blockage taking away a large chunk of edge, the range should reflect the existence of such a blockage. Generally, the order constraints are intended for a collection of pins or ports on a region with continuous available empty wire tracks for pin placement.

If a specific order plus an exact spacing are required for a set of pins, the recommended approach is to define a bundle and constrain the pin order and spacing with *set_bundle_pin_constraints*. See man pages of *create_bundle* and *set_bundle_pin_constraints*.

The following example applies constraints on a design with two block instances *Inst1* and *Inst2*, whose reference block names are *BlockA* and *BlockB*, respectively.

The first two records constrain pins on net *E* connecting block instances *Inst1* and *Inst2*. The next three records constrain the pins *C*, *D* and *F* on reference block *BlockA*. The last record set the order of pins *in[1]*, *in[2]* and *in[3]* on reference block *BlockB*.

```
start physical pin constraints;
{Net E} {cell Inst1} {layers METAL2} {sides 2};
{Net E} {cell Inst2} {layers METAL4} {sides 4};
{Pins C} {reference BlockA} {layers METAL2} {sides 1} {offset {40 50}};
{Pins D} {reference BlockA} {layers METAL2} {width 0.8} {length 0.8};
{Pins F} {reference BlockA} {off_edge} {location {10 10}};
{reference BlockB} {sides 2} {start 10} {end 80} {order {in[1] in[2]
 in[3]}};
end physical pin constraints;
```

The side constraint specifies the side number on which the pin should be inserted for the specified reference block. The side number is a positive integer that starts from one. Given any rectangular or rectilinear shape, the leftmost edge is side number one. If there are multiple leftmost edges, then edge one is the lowest leftmost edge. The sides are numbered in consecutive order proceeded clockwise around the shape. The shape is referring to the reference block's boundary shape.

The offset constraint specifies the distance in microns or percentage from the starting point(positive value) or ending point (negative value) of a specific edge to the routing cross-point on that edge in the clockwise direction. To specify a percentage, append a '%' character to the end of the float value. Percentage can be a value from -100 to 100 only. The starting point is also following the clockwise fashion. For instance, for a bottom horizontal edge, the starting point is the right vertex of the edge as it is counted in clockwise and bottom edge's starting point is right point vertex, vice versa, for ending point is the left vertex of the edge. Since the offset is specific on an edge, you must specify the side information with your offset. The edge here is referring to the reference block's boundary edge.

The location constraints value are referred to the reference cell in the pin constraint entry and therefore, the coordinates are translated to top-level view.

Feedback

A more complicated order constraint is shown in the following example. The pin order *A* and *B* is specified as to be 2 wire tracks in between with *A* first and *B* second. *B* also must use layer M4. Pins *A*, *B*, *C* and *D* must be placed within the region between 20 to 40 microns on side 3 of block *RISC_CORE*. Because pin *C* and *D* are not specified within the {order...} constraint, they can be anywhere within the 20 to 40 micron region on side 3.

```
start physical pin constraints;
{reference RISC_CORE}
  {sides 3} {start 20}
  {end 40} {{order {A {spacing 2} {layers METAL4} B}} {pins {C D}}};
end physical pin constraints;
```

If there are multiple records constraining the same object with conflict settings, the last record overwrites the previous ones.

Finally, pin constraints can be applied by either one of the commands *set_individual_pin_constraints*, *set_bundle_pin_constraints*, or *read_pin_constraints*. But try to use the same method to apply the constraints if possible so as to avoid unwanted conflict between different methods. If unclear whether or not the database was applied constraints before, or the type of the constraints applied, use *remove_individual_pin_constraints* or *remove_bundle_pin_constraints* to clear them.

Pin Spacing Control

The pin spacing control section specifies pin spacing constraints for individual edges on each block cell.

Each record specifies the pin spacing constraints for one or more edges on one or more layers for a particular block cell. The constraint contains the reference, side, and layer keywords. Keywords are case insensitive.

In addition, for those edges specified in the pin spacing control section, those layers that are NOT listed are NOT allowed for pin placement. Furthermore, if those listed layers are NOT allowed in the corresponding reference blocks, they are NOT allowed for pin placement either.

```
start pin spacing control;
{reference ref_cell_name} {sides {side_a side_b}}
{layer_a spacing_a} {layer_b spacing_b};
end pin spacing control;
```

The reference keyword specifies the block reference that this constraint applies to. For a block cell, this constraint refers to the reference cell name, not the cell instance name, if it is to constrain the top level.

The sides keyword specifies one or more sides of the block. If there is more than one side, specify the side number within curly brackets separated by white space. You can use a wildcard character (*) to specify that all sides are allowed.

Feedback

After the side constraint, layer and spacing constraints are specified as pairs. You can specify multiple layer-spacing pairs. The layer value is the layer name. The spacing value is the minimum number of wire tracks between adjacent pins for the specified layer.

In the following example, the CPU block cell is constrained to minimum pin spacing of 2 wire tracks on layer M2, a minimum pin spacing of 3 wire tracks on layer M4, and minimum pin spacing of 3 wire tracks on layer M6 for sides 2 and 4 of the block:

```
start pin spacing control;
{reference CPU} {sides 2 4} {METAL2 2} {METAL4 3} {METAL6 3};
end pin spacing control;
```

Keywords are case insensitive. The reference name and the layer name are case-sensitive.

If a line contains a syntax error, the line is ignored. The command issues warnings or errors that report any lines that are ignored.

If the pin spacing control section contains conflicting constraints for the same edge, same layer and the same block, the last constraint takes priority.

Block Pin Constraints

The block pin constraints section specifies pin constraints that apply to all the pins of the specified block cell.

You can specify block-related pin constraints for feedthroughs, layers, spacing, corner keepouts, hard pin constraints, sides and exclude sides. The same constraint can be set with the *create_block_pin_constraint* Tcl command. Supported keywords are: reference, sides, exclude_sides, layers, feedthrough, spacing, spacing_distance, corner_keepout_distance, corner_keepout_num_tracks and hard_constraints.

The following example sets pin constraints:

```
start block pin constraints;
{reference DATA_PATH}
  {layers {METAL3 METAL4 METAL5}}
  {feedthrough true}
  {corner_keepout_num_tracks 1}
  {spacing 5}
  {exclude_sides {2 3}};

{reference ALU}
  {layers {METAL3 METAL4 METAL5}}
  {feedthrough true}
  {hard_constraints {spacing location layer}}
  {sides {2 3}};
end block pin constraints;
```

You can use the *write_pin_constraints* command to write out block cell pin constraints to a file, and use the *read_pin_constraints* command to read the file.

Feedback

Bundle Pin Constraints

The bundle pin constraints section specifies bundle pin-related constraints. This section is now included in physical pin constraints section.

You can specify whether bundle pin constraints are honored or not during pin placement. The same constraints can be set with the *set_bundle_pin_constraints -keep_pins_together true|false* command. The following example sets bundle pin constraints:

```
start physical pin constraints;
{bundle bundle_0} {keep_bundle_pins_together true};
end physical pin constraints;
```

You can use the *write_pin_constraints* command to write out the bundle pin constraints to a file, and use the *read_pin_constraints* command to read the file.

Conflicts

When there is a conflict between a topological map constraint and a physical pin constraint, topological map constraints takes priority over physical pin constraints for global routing and pin placement.

The constraint file can have multiple topological map sections or multiple physical pin constraints sections. If same object is listed multiple times with the same constraint, the last record takes priority. If the same object is listed multiple times with different constraints, the constraints are combined.

Examples

The following example reads the pin_cstr pin constraint file.

```
prompt> read_pin_constraints -file_name pin_cstr
```

A complete pin constraints file example is shown as follows:

```
start topological map;
{nets net_B}
{{{cell Cell_A} {sides 1}
  {offset 20.18} {layers M2}}
 {{cell  Cell_B} {sides 3}
  {offset 40.28} {layers M4}}
 {{cell  Cell_C} {sides 1}
  {offset 30.28} {layers M4}}
 {{cell  Cell_D} {sides 3}
  {offset 15.88} {layers M2}}};
end topological map;

start feedthrough control;
{nets Xecutng_Instrn[0]}
  {NoFeedthrough {I_ALU I_REG_FILE I_STACK_TOP}};
end feedthrough control;
```

Feedback

```
start physical pin constraints;
  {pins C} {reference B} {layers METAL2 METAL4} {sides 2};
  {pins D} {reference B} {sides 2};
  {net C/A} {layer METAL4};
  {bundle bundle_0} {keep_bundle_pins_together true}
end physical pin constraints;

start pin spacing control;
{reference C} {sides 2 4} {METAL2 2} {METAL4 3} {METAL6 3};
end pin spacing control;

start block pin constraints;
{reference DATA_PATH}
  {layers {METAL3 METAL4 METAL5}}
  {feedthrough true}
  {corner_keepout_num_tracks 1}
  {spacing 5}
  {exclude_sides {2 3}};

{reference ALU}
  {layers {METAL3 METAL4 METAL5}}
  {feedthrough true}
  {hard_constraints {spacing location layer}}
  {sides {2 3}};
end block pin constraints;
```

---

read_power_profile

Read Power Profile from file

Syntax

status *read_power_profile*

```
[-file file_path]
[-result result_name]
```

Data Types

```
file_path           string
result_name         string
```

Feedback

Arguments

`-file` *file_path*

Specifies the file path of the Power Profile. If the file path is not specified, the created Power Profile has no power region. The default is "".

`-result` *result_name*

Specifies the thermal result name of input power to open. The default is "default".

Description

This command creates in-memory Power Profiles by reading Power Profile files. The loaded Power Profiles can be visualized using 'Power Profile' map.

Examples

The following examples create in-memory Power Profiles by reading Power Profile files.

```
prompt> read_power_profile
prompt> read_power_profile -result MyPowerResult
prompt> read_power_profile -file ./profile.spr
```

See Also

- remove_power_profiles

---

read_rde

Reads RDE model from a encrypted file for current design.

Syntax

status *read_rde*

file_name [-help]

Data Types

```
file_name        string
```

Arguments

`file_name`

Specifies the name of the input file from which a RDE model for the current design are read.

`-help`

Specifies the usage of read_rde

Feedback

Description

This command reads the RDE model for the current design from a file. The file is an encrypted format generated by the "write_rde" command. For very large designs, the runtime of the RDE capture step can be reduced by dumping the RDE model from a prior run with "write_rde" and reading it back into a successive run with "read_rde". Once the RDE model information is read in, before either the place_opt or clock_opt flow stages, the subsequent RDE capture step(s) will be skipped subject to the following use model. A RDE model dumped after place_opt (final_opto) may be reused only by the place_opt call of the successive run. An RDE model dumped after clock_opt may be used in both the place_opt and clock_opt stages of the new run (the model need only be read in one time, before either place_opt or clock_opt). The "read_rde" command includes some checking as to whether there have been floorplan changes and, if so, may not allow the RDE model to be read in. In this case, the user should run the default flow and regenerate new RDE model information after the RDE capture stages if desired.

USAGE

run 1 : place_opt -from final_opto write_rde place_opt_RDE ... clock_opt -from final_opto write_rde clock_opt_RDE

run 2 : read_rde place_opt_RDE OR read_rde clock_opt_RDE place_opt -from final_opto ... read_rde clock_opt_RDE clock_opt -from final_opto

Examples

The following example reads a RDE model for the current design.

```
prompt> read_rde -help
Usage: read_rde    # a RDE stream in command
        [file_name]            (filename to read in)
prompt> read_rde my.rde
```

See Also

- write_rde

---

read_saif

Reads a Switching Activity Interchange Format (SAIF) file and annotates switching activity information on the nets, pins, and ports in the current design.

Syntax

status *read_saif*

```
file_list
[-strip_path source_name]
[-path target_name]
```

Feedback

```
[-scenarios scenario_list]
[-modes mode_list]
[-corners corner_list]
[-exclude_sdpd]
[-normalize true | false]
[-nocase]
[-report]
[-use_highest_toggle_rate]
[-derate_glitch derate_value]
[-ignore_name_mapping]
```

Data Types

```
file_list              list
source_name            string
target_name            string
scenario_list          list
mode_list              list
corner_list            list
derate_value           double
```

Arguments

file_list

Specifies a list of SAIF files to be read. The file can be a simple ASCII file or a compressed gzip file.Each list item consists of the SAIF file name and optionally the weight, scaling ratio, strip path, and the path. The syntax for each list item is

```
file_name
   [-weight weight_value]
   [-scaling_ratio scaling_ratio_value]
   [-strip_path source_name]
   [-path target_name]
```

The default for the *-weight* and *-scaling_ratio* options is 1.0 and when specified must be larger than 0.0. The *-strip_path* and *-path* options can be specified either individually for each file or once for all the files when multiple files have the same strip path or path.

`-strip_path source_name`

Specifies the name of the instance of the current design as it appears in the SAIF file. The current design appears as an instance in the SAIF file. The *read_saif* command annotates all subinstances in the hierarchy of the specified instance, and annotates the instance itself. Each instance name that is specified must be complete, but without any trailing hierarchy separator (/). Automatic search is enabled when -strip_path option is not specified. Automatic search uses the path cell name(just the cell name which doesn't include path name) and search its occurences in full Saif. Whichever Saif instances matches, it annotates them on the path instance. Automatic search generates POW-128

Feedback

message indicating which Saif instances matched with the specified path instance. Automatic search is useful when there is only one occurence of specified path cell name in Saif. It might not give intended result if path cell name has multiple occurences in Saif. Specify -strip_path with -path option to annotate specified Saif instance on path instance.

`-path` *`target_name`*

Specifies the target instance on which the switching activity in the SAIF file is to be annotated. If this option not specified, the current instance is assumed to be the target instance.

`-scenarios` *`scenario_list`*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through *-modes* and *-corners* options. Activity annotation is done separately for each scenario. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, annotation is done for the current scenario in the design.

`-modes` *`mode_list`*

Specifies the mode filter on the set of scenarios to be considered. A scenario is considered if its mode is present in *mode_list*. If this option is not specified, no filtering occurs on modes.

`-corners` *`corner_list`*

Specifies the corner filter on the set of scenarios to be considered. A scenario is considered if its corner is present in *corner_list*. If this option is not specified, no filtering occurs on corners.

`-exclude_sdpd`

When specified, the state-dependent and path-dependent (SDPD) switching activities are ignored while reading saif files. By default, the SDPD activities are read from saif files.

`-normalize true | false`

Controls whether the weight associated with each SAIF file is normalized, which means that the sum of the weighted activity values is divided by the sum of the weights.

By default (*true*), the command normalizes the weights.

If the value is *false*, the command uses the weights as specified.

Feedback

`-nocase`

When specified, the SAIF file is matched without considering the name case of the objects specified. The object matching is done in name-case insensitive manner.

`-report`

When specified, the command generates a summary which indicates number of objects present in saif file which were found in the design and also number of objects present in design which were found in the saif file. If this option is not specified, command summary is not generated.

`-use_highest_toggle_rate`

When this option is used, the non-SDPD activity with the highest toggle rate is selected from the list of specified SAIF files. When this option is specified, SDPD activities are ignored. This option cannot be used with the option *normalize* and *weight*.

`-derate_glitch` *`derate_value`*

Specifies the default derate glitch value to be used if no derate glitch is specified in SAIF file.

`-ignore_name_mapping`

Reads a SAIF file generated from the current design where no name mapping needs to be performed. For example, when reading a gate level SAIF file generated from the same netlist. This allows the existing name mapping database to be preserved but not used for the *read_saif command*.

Description

The *read_saif* command reads a list of SAIF files and annotates the switching activity attributes *rise_toggle_rate*, *fall_toggle_rate*, and *static_probability* for nets, ports, and pins of the current design. If a particular object in the SAIF file cannot be found in the current design, the object is ignored and a warning message is provided. The *read_saif* command returns 1 if at least one of the objects in the file is successfully annotated. Otherwise, it returns 0. This command resets the switching activity for the design before reading the specified SAIF files. For merging of SAIF files, one can read multiple SAIF files. The probabilities are multiplied with the weight factor and accumulated overall SAIF files. The toggle rates are multiplied with the weight factor and the scaling factor and accumulated over all SAIF files. The resulting probability and toggle rate is normalized (divided by the sum of weights), except when option -normalize false is used.

Whenever the *-nocase* option is used, the SAIF file is interpreted ignoring the name cases of the objects specified in SAIF file. An object with name 'ABC' in SAIF can be matched to object 'abc' in the netlist and vice-versa.

Feedback

SAIF information is saved with a block unless the application option *power.enable_activity_persistency* is set to off.

Examples

The following example annotates switching activity for the current block.

```
prompt> read_saif test.saif
```

The following example annotates switching activity for the current block that has been annotated as Test/U1 in simulation testbench.

```
prompt> read_saif test.saif -strip_path Test/U1
```

The following example annotates switching activity from the SAIF file for the instance Mult/U12 in the current block.

```
prompt> read_saif test.saif -path Mult/U12
```

The following example annotates the switching activity from a SAIF file and then reports it using the *get_switching_activity* command. The toggle rate values and static probability are derived from the SAIF file and the activity type is set to 'simulated'.

```
prompt> read_saif test1.saif
prompt> get_switching_activity [get_pins GPRs/iso]
(mode = default, corner = default, probability = 0.504926,
rise_toggle_rate = 9.61391e+06, fall_toggle_rate = 9.61391e+06,
type = simulated)
```

The following example merges two SAIF files test1.saif and test2.saif. The probabilities for the annotated cells are (1 * probability(test1.saif) + 2 * probability(test2.saif)) / 3, and the toggle rates are ((1 * 4 * toggle_rate(test1.saif) + 2 * 3 toggle_rate(test2.saif)) / 3. Since individual strip paths have not been specified per file, strip path for both are ChipTop. Path for test1.saif file is InstDecode, and for test2.saif file is GPRs.

```
prompt> read_saif {{test1.saif -scaling_ratio 4 -path InstDecode} \\
   {test2.saif -weight 2.0 -scaling_ratio 3.0}} \\
   -strip_path ChipTop -path GPRs
```

The following example merges two SAIF files test1.saif and test2.saif under the option use_highest_toggle_rate. The non-SDPD toggle rate and probabilities for the annotated cells are chosen to be those of the one with highest toggle rate amongst test1.saif and test2.saif. When this option is specified, SDPD activities are ignored.

```
prompt> read_saif -use_highest_toggle_rate {{test1.saif} {test2.saif}}
```

---

read_sdc

Reads in a script in Synopsys Design Constraints (SDC) format.

Syntax

status *read_sdc*

file_name [-echo] [-syntax_only] [-version *sdc_version*]

Data Types

```
file_name    string
sdc_version  string
```

Arguments

file_name

Specifies the name of the file that contains the SDC script to read.

-echo

Echoes each constraint as it is executed.

-syntax_only

Checks only the syntax and semantics of the SDC script.

-version *sdc_version*

Specifies the version of SDC to which the file conforms.

Allowed values are 1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, and *latest* (the default).

Description

The *read_sdc* command reads in a script file in Synopsys Design Constraints (SDC) format. SDC is also licensed by external vendors through the Tap-in program.

By default, the *read_sdc* command executes the constraints as they are read. If there are errors in the script, it is possible that some constraints are applied, and some are not. You can use the *-syntax_only* option to check the script without applying any constraints. This

Feedback

also verifies conformance to the specified SDC version. If there are any errors during the checking phase, the result of the *read_sdc* command is 0.

Like the *source* command, the *read_sdc* command is sensitive to variables that control script execution, such as *sh_continue_on_error* and *sh_script_stop_severity*. The *read_sdc* command uses the *sh_source_uses_search_path* variable to determine if the *search_path* variable is used to find the script.

The *read_sdc* command supports several file formats. The file can be a simple ASCII script file, an ASCII script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler.

Note that SDC does not allow command abbreviation. Also, the *exit* and *quit* commands do not cause the application to exit, but they do cause the reading of the SDC file to stop.

The latest SDC version supports the following commands. Those added for versions 1.3 and later are noted. Th list does not include some constraints that are ignored by the tool.

General Purpose Commands:

```
expr
list
set
```

Object Access Functions:

```
all_clocks
all_inputs
all_outputs
all_registers (1.7)
current_design
current_instance
get_cells
get_clocks
get_libs
get_lib_cells
get_lib_pins
get_nets
get_pins
get_ports
set_hierarchy_separator
```

Basic Timing Assertions:

```
create_clock
create_generated_clock (1.3)
group_path (1.7)
set_clock_gating_check
set_clock_groups (1.7)
set_clock_latency
set_clock_sense (1.7)
set_clock_transition
```

Feedback

```
set_clock_uncertainty
set_data_check (1.4)
set_false_path
set_ideal_latency (1.7)
set_ideal_transition (1.7)
set_input_delay
set_max_delay
set_min_delay
set_multicycle_path
set_output_delay
set_propagated_clock
```

New options to existing supported commands:

```
create_clock -add (1.4)
create_generated_clock -add
create_generated_clock -master_clock
create_generated_clock -combinational (1.7)
```

Secondary Assertions:

```
set_disable_timing
set_max_time_borrow
set_timing_derate   (1.5)
```

Environment Assertions:

```
create_voltage_area
set_case_analysis
set_drive
set_driving_cell
set_fanout_load
set_input_transition
set_ideal_network (1.7)
set_level_shifter_strategy
set_level_shifter_threshold
set_load
set_logic_dc
set_logic_one
set_logic_zero
set_max_area
set_max_capacitance
set_max_dynamic_power
set_max_leakage_power
set_max_transition
set_min_capacitance
set_min_fanout
set_min_porosity
set_operating_conditions
set_port_fanout_number
set_voltage (1.8)
set_wire_load_min_block_size
set_wire_load_mode
```

Feedback

```
set_wire_load_model
set_wire_load_selection_group
```

For a complete guide to using SDC with Synopsys tools, see the *Using the Synopsys Design Constraints Format Application Note*, which is available in SolvNet at https://solvnet.synopsys.com.

The usage of some of the supported commands is restricted when reading SDC. In some cases, some options are not allowed. In some tools, some of the commands, such as the *set_logic** commands, are not supported. If the SDC file contains a command that is not supported by the tool, the *read_sdc* command ignores the command and issues a warning message (for an example, see the EXAMPLES section). If the SDC file contains a command or option that is not supported by the SDC format, the *read_sdc* command issues an error message.

Multicorner-Multimode Support

This command works only on the current scenario.

Examples

The following example reads the SDC script named top.sdc.

```
prompt> read_sdc top.sdc -version 1.2

Reading SDC version 1.2...
1
```

The following example reads the SDC script named top2.sdc. The script contains commands not supported by SDC, so the *read_sdc* command issues CMD-005 messages for those commands.

```
prompt> read_sdc -syntax_only top2.sdc -version 1.2

Checking syntax/semantics using SDC version 1.2...

Error: Unknown command 'link_design' (CMD-005)

** Completed syntax/semantic check with 1 error(s) **
0
```

The following example shows the result when the SDC file contains a command that is not supported by the tool. One SDC message is generated per instance of an unsupported command. At the end of the read, the command generates a summary of all unsupported commands in the file. The SDC file is read into the tool.

```
prompt> read_sdc t2.sdc -version 1.2

Reading SDC version 1.2...
Warning: Constraint 'set_logic_zero' is not supported by the tool.
 (SDC-3)
```

```
Warning: Constraint 'set_logic_zero' is not supported by the tool.
 (SDC-3)
Warning: Constraint 'set_logic_one' is not supported by the tool. (SDC-3)

Summary of unsupported constraints:
Information: Ignored 1 unsupported 'set_logic_one' constraint. (SDC-4)
Information: Ignored 2 unsupported 'set_logic_zero' constraints. (SDC-4)
1
```

The following example shows the output generated by the *read_sdc* command when reading an SDC file with unsupported options. In an SDC file, the *current_design* can be used only to get the current design; no arguments are allowed.

```
prompt> read_sdc t3.tcl -echo -version 1.2
Reading SDC version 1.2...
current_design TOP
Error: extra positional option 'TOP' (CMD-012)
0
```

---

read_signal_em_constraints

Reads the signal electromigration rules.

Syntax

```
status read_signal_em_constraints
[-encrypted]
[-format ITF | ALF | IRCX]
file_name
```

Data Types

```
file_name      string
```

Feedback

Arguments

`-encrypted`

Indicates that the electromigration file is encrypted. This option is exclusive with the option *-format*.

`-format ITF | ALF | IRCX`

Specifies the electromigration file format. The supported formats are *ITF*, *ALF*, and *IRCX*, and if this option is not specified, the data will be read as *ITF* format by default. This option is exclusive with the option *-encrypted*.

`file_name`

Specifies the constraint file from which to import signal electromigration data into the current design library. The specified constraint file should contain only signal electromigration information.

Description

The *read_signal_em_constraints* command reads signal electromigration data into the current design library. If the design library already contains signal electromigration information, it is replaced by the data in the new constraint file.

The command returns 1 if the file is successfully read in; otherwise, it returns 0.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The first example reads a signal electromigration file named test.itf into the current design library. The second example reads a encrypted signal electromigration file named test.itf.enc into the current design library. The third example reads a signal electromigration file named test.alf into the current design library. The fourth example reads a signal electromigration file named test.ircx into the current design library.

```
prompt> read_signal_em_constraints test.itf
prompt> read_signal_em_constraints -encrypted test.itf.enc
prompt> read_signal_em_constraints -format ALF test.alf
prompt> read_signal_em_constraints -format IRCX test.ircx
```

See Also

- current_lib
- read_tech_file
- search_path

Feedback

read_tech_file

Reads a technology file into the current library.

Syntax

```
status read_tech_file
file_name
[-merge]
[-convert_sites convert_sites]
```

Data Types

```
file_name       string
convert_sites   list
```

Arguments

file_name

Specifies the technology file you want to read.

-merge

Specifies the add-on technology data to be merged to baseline in existing library

-convert_sites *convert_sites*

Specifies the list of technology file sites to convert. This option can be used only with the *-technology* option.

Description

The *read_tech_file* command reads a technology section into the current library. If the sites are defined in the technology file, the *-convert_sites* option can be used to map them from one name to another. The same option exists in the *read_def* command to make the site names match among all the input data.

If a new technology file has missing layers that are defined in the existing technology data, or if some layers have different names or numbers, the *read_tech_file* command allows the replacement. In these cases, the tool issues information messages, and existing objects on the missing layers become unbound objects. When layers are recreated or read in through another technology file replacement, these objects are rebound to the layers.

Examples

The following example read in a technology file "tcb90g.tf" into the current library.

```
prompt> read_tech_file tcbn90g.tf
Information: technology file '/user/joe/work/tcbn90g.tf' is loaded
{"r4000"}
prompt> read_tech_file 3dic1.tf -merge
```

Feedback

- search_path

---

read_tech_lef

Reads one or more LEF (Library Exchange Format) technology data files.

Syntax

string *read_tech_lef*

```
[-design design]
[-merge_action add | ignore | overwrite | update]
[-syntax_only]
file_names
```

Data Types

```
design                collection
file_names             list
```

Arguments

`-design design`

Specifies the block in which to create the LEF technology data. If this is not specified, LEF technology data will be created in the current block.

`-merge_action add | ignore | overwrite | update`

Specifies the strategy for merging LEF data into an existing block. The strategy is used only when there has a matched object found in existing block. The definition for each option value is:

- *add* (the default) : Adds a new object to existing block by making name unique
- *ignore* : Skips the new object
- *overwrite* : Deletes the existing object in block, and then create the new object.
- *update* : Combines the new object with the existing object in block, retaining both data sets. For objects that do not have components, this will be same as overwrite. For objects that have components, the merge depends on the

Feedback

components. For components that should be unique or already exists, the command overwrites them. For components that do not have name or do not exist yet, the command adds them.

`-syntax_only`

Specifies that the LEF files are processed only to check the syntax and semantics of the files.

`file_names`

Specifies names of one or more LEF files to be read.

Description

The command reads LEF technology data into an existing block.

To locate files that have relative path names, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path*. Files that have absolute path names are loaded as though there were no *search_path*. To determine the file that *read_tech_lef* loads, use the *which* command.

The *-merge_action* option customize how LEF technology data is merged into the existing block.

This command is only available in *icc2_shell*.

Examples

The following example reads the file via_rule.lef file.

```
prompt> read_tech_lef via_rule.lef
1
```

The following example reads via_rule.lef into an existing block called my_block and ignores an object if it already exists in the block.

```
prompt> read_tech_lef via_rule.lef -design my_block -merge_action ignore
```

- search_path

---

read_test_model

Reads a test model file.

Syntax

```
status read_test_model
[-format ctl | icl | pdl | ict | wks | hdl]
[-design design_name]
```

Feedback

```
[-type wrapped | unwrapped]
[-class ieee1500 | ieee1687 | ieee1149]
[-append on | off]
filename
```

Data Types

```
format          string
design          string
type            string
class           string
append          string
filename        string
```

Arguments

`-format ctl | icl | pdl | ict | wks | hdl | dft_db`

Specifies the format of the test model. By default, the test model is in .ctl format. Specift dft_db format (xml file path) to read lower level information of a design

`-design` *design_name*

Specifies the design associated with the test model. This option is applicable to formats such as ict, zip, wks, hdl, icl, pdl, and masis. By default, the test model is associated with the current design.

`-type wrapped | unwrapped`

Specifies whether the lower-level blocks are wrapped with the IEEE 1500 or IEEE 1687 test interface or not. This option is applicable only to the *icl* and *masis* arguments of the *-format* option.

`-class ieee1500 | ieee1687 | ieee1149`

For wrapped blocks, this option specifies the existing test interface. For unwrapped blocks, this option specifies the required test interface. This option is applicable only to the *icl* and *masis* arguments of the *-format* option.

`-append on | off`

Specify this option when users wants to read multiple test model of same format for same design. This option is applicable only to the *wks* and *ict* arguments of the *-format* option.

file_name

Specifies the test model files to read. This argument is required. When you specify the format as *ctl*, you can specify only one file.

Description

The *read_test_model* command reads test model files.

Feedback

The test model files represent the test behavior of designs. The attributes include all DFT signals and their purpose, test timing, and the sequence of events needed to shift test vectors in and out of the design. The *read_test_model* command reads only the test model and the interface definition of a design and ignores any other information. Because the gate-level implementation of a design is not needed, significant memory and runtime savings can be achieved.

A successful read of a model overwrites any test model information in the memory.

For the IEEE 1838 standard, TAP port specifications inside the internal statment of the test mode should adhere to the following points:

- *Primary TAP*: User data should contain both IEEE 1149.1 and IEEE 1838 standards to define the port as a primary TAP. The last user data defines the name of the TAP set, which is optional for PTAP ports.

  For example,

```
"tdo" {
                DataType ScanDataOut User "IEEE1149.1"  User
 "IEEE1838" User "TAP set name"
                {
                  ScanDataType Internal;
                }
              }
```

- *Secondary TAP:* User data should contain only the IEEE 1838 standard to define the port as a secondary TAP. The last user data defines the name of the die to which the port belongs. If there are multiple STAP dies, you must provide the set name.

  For example,

```
"myStapTdo" {
                DataType ScanDataOut User "IEEE1838"  User "STAP set
 name"
                {
                  ScanDataType Internal;
                }
            }
```

Test models are stored on disk using the *write_test_model* command.

Examples

```
prompt> current_design
{des_unit.nlib:des_unit.design}

prompt> read_test_model myModel.ctl

File name: myModel.ctl

Warning: CTL Model read for design des_unit (DFT-2000)
```

Feedback

- write_test_model

---

read_test_protocol

Reads a STIL test protocol file into memory.

Syntax

status *read_test_protocol*

```
[-section section_name]
[-test_mode test_mode_name]
[-pattern_exec pattern_exec_name]
[-file_name input_file_name]
```

Data Types

```
section_name        string
test_mode_name      string
pattern_exec_name   string
input_file_name     string
```

Arguments

`-test_mode test_mode_name`

Specifies a test mode name to read and store a test protocol. If not specified, the current test mode is used by default. This option is only supported when updating the post-DFT test protocol.

`-pattern_exec pattern_exec_name`

Specifies a PatternExec name to read and store a test protocol. The options -test_mode and -patternexec are mutually exclusive.

`-section section_name`

Specifies a section name of the protocol. With this option, the *read_test_protocol* command reads only the specified section and ignores others. The only valid parameter value is *test_setup*, which describes the initialization sequence.

`-file_name input_file_name`

Specifies the name of the test protocol file in STIL format to read.

Description

This command reads a test protocol file into memory. Reading a test protocol file defines the scan test protocol for the current design.

Feedback

The scan test protocol provides a means to formally define the process by which a design is tested, such as the sequence of scan-in vectors, parallel vectors, and scan-out vectors performed for each test pattern. The protocol defined for a design is used to drive scan-test design rule checking.

The format of the test protocol file is STIL. See the TestMAX DFT and TestMAX ATPG user guides for details of the protocol file format.

The *read_test_protocol* command enables you to define an arbitrary test protocol for a design by reading in a text file describing the protocol. Use *write_test_protocol* to write out an existing protocol for a design in the same text format.

Normally, this command removes any protocol that may be present in memory through the previous use of the *read_test_protocol* or *create_test_protocol* commands.

When the *read_test_protocol -section test_setup* command is executed before pre-DFT DRC has been performed, the *test_setup* section from the specified protocol file is read in and used in place of the default setup protocol created by the tool. The provided *test_setup* section must include all preconditioned signals defined by the *set_dft_signal* command, such as clock, set, reset, and constant signals. Any STIL *Loop* constructs are retained as they are.

To modify the default setup protocol used by pre-DFT DRC, you can write out the default test protocol, modify the *test_setup* section, then read it back in; see the EXAMPLES section for more information.

When the *read_test_protocol -section test_setup* command is executed after DFT insertion has been performed, the *test_setup* section of the in-memory test protocol created by DFT Compiler is merged with the *test_setup* section from the specified protocol file. This merged in-memory protocol is used for any subsequent DRC. Any STIL *Loop* constructs are unrolled during this merging process. If multiple test modes were created by DFT Compiler, you can update each one using the *-test_mode* option of this command, or the *current_test_mode* command.

With the STIL protocol format, you cannot distinguish between a clock signal and an asynchronous signal. You must define asynchronous signals with the *set_dft_signal* command before reading your custom STIL protocol.

Examples

The following example reads a test protocol from the *newUPC1.spf* file:

```
prompt> read_test_protocol newUPC1.spf
Reading test protocol file 'newUPC1.spf'...
```

Feedback

The following example reads a test protocol for the *UPC1* design from the *UPC1.spf* default file:

```
prompt> read_test_protocol
Reading test protocol file 'UPC1.spf'...
```

The following example defines the asynchronous signal *rstn* for design UPC1 and reads a test protocol from the file UPC1.spf:

```
prompt> set_dft_signal -type Reset -active_state 0 -port rstn

prompt> read_test_protocol UPC1.spf
```

The following example reads a *test_setup* section of the protocol. For example, assume that the *init_sequence.spf* file has the following *test_setup* vector sequence:

```
MacroDefs {
  "test_setup" {
    W "_default_WFT_";
    V { "A" = 0; "B" = 0; "CP" = 0; }
    V { "A" = 1; "B" = 1; "CP" = P; }
    V { "A" = 0; "B" = 0; "CP" = 1; "AA" = 1; "BB" = 1; }
  }
}
```

The following command reads in the initialization sequence and ignores the rest of the protocol file:

```
prompt> read_test_protocol -section test_setup init_sequence.spf
```

The following example creates a default test protocol, modifies it, and reads the modified *test_setup* back in:

```
prompt> create_test_protocol

prompt> write_test_protocol -output test_setup_mod.spf

  (manually modify test_setup in file,
  keeping pre-conditioned signals as needed)

prompt> read_test_protocol -section test_setup test_setup_mod.spf
```

The following example updates the post-DFT test setup protocol for two test modes:

```
prompt> insert_dft

prompt> read_test_protocol -section test_setup \\
          -test_mode Internal_scan postDFT.spf

prompt> read_test_protocol -section test_setup \\
          -test_mode ScanCompression_mode postDFT.spf
```

Feedback

```
prompt> current_test_mode Internal_scan

prompt> dft_drc

prompt> current_test_mode ScanCompression_mode

prompt> dft_drc
```

---

read_thermal_info

Reads thermal derating factor tables.

Syntax

int *read_thermal_info*

```
[-derate]
[-debug]
thermal_lib_cell_derate_file
```

Data Types

```
thermal_lib_cell_derate_file     string
-derate                          option
-debug                           option
```

Arguments

-derate

Thermal derate flow: The -derate option is provided to allow user to specify that input is thermal_derates_file for all lib cells.

-debug

The -debug option is provided to print thermal derates for all lib cells specified in the thermal derate side file.

thermal_lib_cell_derate_file

Specifies the name of the Thermal lib cell derate file.

Feedback

Description

The *read_thermal_info* command reads Thermal lib cell derate factor tables from a file. The lib cell derate tables are annotated onto all corners of design. The Thermal data is used to improve the accuracy of timing numbers based on thermal analysis.

Set the app option *time.enable_thermal_analysis* to enable Thermal analysis.

Note that a net inherits the Thermal derate set of the driving lib cell.

Thermal derating is applied to all cells in the design if the specific Library cell has derating information available in Thermal side file.

Tables are processed in the order that they appear in the Thermal side file. The last table of a specific type {lib_cell, rf_type, delay_type, derate_type} to be defined for an object in the file overwrites previous tables defined for the same object of the same type.

The *read_thermal_info* command can read text format Thermal derate side files supplied by foundry. This file has the following sections:

1. Thermal bins: bin index to Temperature
2. Thermal derates section: For each lib cell, derate for cell min/max, rise/fall, nominal/sigma derates.

Multicorner-Multimode Support

By default, this command sets the thermal derates from side file to all corners.

Examples

Thermal Derate Side file: The following example shows an Thermal derate file, with 8 temperature bins in Temperatures section. The Derates section has 3 cells with Nominal Cell Rise/Fall, Min/Max derates annotated on all the corners.

---

read_verilog

Reads in one or more Verilog files.

Syntax

```
string read_verilog
[-library library_name]
[-design design_name]
[-top module_name]
file_names
```

Data Types

library_name	string
design_name	string
module_name	string
file_names	string

Arguments

`-library` *library_name*

Specifies the name of the library to contain the design. If the current library is not set, the command creates a library using the first input file name. By default, the command saves the design into the current library. If the reference library list is not set, then issues a warning.

`-design` *design_name*

Specifies the name of the design and label to read in, in designName[/labelName] format. If design name is not specified, the top module is used as

Feedback

the design name. If label name is not specified, the default label, specified with the file.verilog.default_user_label app_option, will be used. Reading into an opened design is not allowed. The design must not already exist or be closed.

`-top` *`module_name`*

Specifies the name of the top module in the design hierarchy. By default, the top module is the module that is not instantiated by any other modules.

`-as_block`

Specifies that a new block should be created to store the read modules.

`file_names`

Specifies the names of one or more input Verilog netlist files.

Description

Reads one or more structural, gate-level Verilog netlists into the tool. To locate Verilog files that have relative pathnames, the command uses the *search_path* variable and searches for each file in each directory listed in the *search_path*. Files with absolute pathnames are loaded independent of the *search_path* variable. Use the *which* command to determine the file that *read_verilog* loads. After reading the Verilog files with the *read_verilog* command, use the *list_blocks* command to view the design objects. To remove designs, use the *remove_block* command.

The command saves the read modules into the current block if there is an open current block defined, and the block is not yet linked. This behavior can be disabled so a new block is created with the -as_block argument, or if -design is used.

When targeting an existing block a redefinition of a module will overwrite an existing definition.

The Verilog netlists must contain fully-mapped, structural designs. The tool cannot link or perform timing analysis with netlists that are not fully mapped at the gate level. There must be no high-level Verilog constructs in the netlist.

The Verilog file can be a simple ASCII file or a compressed gzip file. Each gzip file is uncompressed to a temporary file in the directory defined by the *icc2_tmp_dir* variable.

Generally, the Verilog reader does not create unconnected nets and discards unconnected instances. To keep unconnected nets in your design, set the *file.verilog.keep_unconnected_nets* app option to *true*. Also, if a module has one or more references to a reference name, but no instances have connections, those instances are omitted if the *file.verilog.keep_unconnected_cells* app option is set to "false" (the default). Discarding unconnected instances saves memory for instances of filler cells and other cells with no pins.

Feedback

Additionally, *read_verilog* command prints summary at the end of run. The following describes each field:

- Number of modules read: <no. of modules read from verilog file>
- Top level ports: <no. of ports in top module including PG ports>
- Total ports in all modules: <total no. of ports in all the modules including PG ports>
- Total nets in all modules: <total no. of nets in all the modules including PG nets>
- Total instances in all modules : <total no. of instances in all the modules>
- Elapsed = <clock time>, CPU = <cpu time>

Limitations of the Verilog Reader

The Verilog reader has the following limitations:

- No non-structural constructs are supported. For details, see the "Supported Language Subset for the Verilog Reader".
- Parameters are not supported. Parameter and defparam statements are read and ignored.
- Gate instantiations are not supported.

Supported Language Subset for the Verilog Reader

The Verilog reader supports a small structural subset of the Verilog language. Additional constructs are recognized and ignored. Supported constructs are as follows:

- module/endmodule
- input, inout, and output
- wire
- tri, wor, and wand: These constructs are supported and are treated the same as the wire construct. That is, there is no special significance to these constructs.
- supply0 and supply1: These constructs create wires that are logic 0 and 1, respectively.
- assign
- tran: An exception from the gate instantiation subset, tran is supported to the extent that it relates one wire to another, as with assign. Beyond that, tran has no special significance.
- The preprocessor directives `define, `undef, `include, `ifdef, `else, and `endif are not supported by default. The *read_verilog* command targets structural, machine-generated Verilog, which rarely contains these constructs. Set the

Feedback

file.verilog.enable_vpp app option to true to enable a preprocessor phase that expands these constructs and outputs a temporary file to the directory defined by the *icc2_tmp_dir* variable.

- All simulation directives (for example, `timescale) are recognized and ignored.
- The specify/endspecify construct and its contents are recognized and ignored.
- Like HDL Compiler, the comment directives *translate_off* and *translate_on* are used to bypass Verilog features not supported by the reader. The following example shows how to bypass an unsupported feature:

```
// synopsys translate_off
nand (n2, a1, s2);
/* synopsys translate_on */
```

Examples

The following example defines a search path and reads the newcpu.v Verilog file.

```
prompt> set search_path "/designs/newcpu/v1.6 /libs/cmos"
/designs/newcpu/v1.6 /libs/cmos

prompt> read_verilog newcpu.v
Loading verilog file '/designs/newcpu/v1.6/newcpu.v'
Number of modules read: 6
Top level ports: 124
Total ports in all modules: 514
Total nets in all modules: 598
Total instances in all modules: 18
Elapsed = 00:00:00.00, CPU = 00:00:00.00
1
```

---

read_verilog_outline

Reads one or more Verilog files to create an outline design.

Syntax

string *read_verilog_outline*

```
[-library library_name]
[-design design_name]
```

Feedback

```
[-top module_name]

[-partition | -allocation]
[-target_block_size target_block_size]
[-glue_cell_count glue_cell_count]
[-target_cell_count target_cell_count]
[-large_threshold cell_count_threshold]

[-depth hierarchy_depth]
[-keep_port_depth port_depth]
[-dense_modules dense_module_names]
[-port_modules port_module_names]
[-sparse_modules sparse_module_names]

[-leaf_cells leaf_cell_names]
[-buffer_cells buffer_cell_names]
[-macro_cells macro_cell_names]

file_names
```

Data Types

```
library_name          string
design_name           string
module_name           string
target_block_size     integer
glue_cell_count       integer
target_cell_count     integer
cell_count_threshold  integer
hierarchy_depth       integer
port_depth            integer
dense_module_names    list
port_module_names     list
sparse_module_names   list
leaf_cell_names       list
buffer_cell_names     list
macro_cell_names      list
file_names            list
```

Arguments

`-library library_name`

Specifies the name of the library to contain the design. If the current library is not set, the command creates a library using the first input file name. By default, the command saves the design into the current library. If the reference library list is not set, then issues a warning.

`-design design_name`

Specifies the name of the design and label to read in, in designName[/labelName] format. If design name is not specified, the top module is used as the design name. If label name is not specified, the default label, specified with

Feedback

the file.verilog.default_user_label app option, is used. Reading into an opened design is not allowed. The design must not already exist or be closed.

`-top` *`module_name`*

Specifies the name of the top module in the design hierarchy. By default, the top module is the module that is not instantiated by any other modules.

`-partition`

Use the partition method to select dense modules.

`-allocation`

Use the allocation method to select dense modules.

`-target_block_size` *`target_block_size`*

Specifies the target for the number of cells in each partition block.

`-glue_cell_count` *`glue_cell_count`*

Specifies the target for the number of leaf cells to allocate for glue modules of the partition blocks.

`-target_cell_count` *`target_cell_count`*

Specifies the target for the total number of leaf cells to create.

`-large_threshold` *`cell_count_threshold`*

Specifies the number of leaf cells that a module can contain before it is considered to be a large module.

`-depth` *`hierarchy_depth`*

Specifies the number of top levels of module hierarchy to make dense.

`-keep_port_depth` *`port_depth`*

Specifies the number of levels of module hierarchy to preserve port interfaces.

`-dense_modules` *`dense_module_names`*

Specifies a list of module names to have dense representations.

`-port_modules` *`port_module_names`*

Specifies a list of module names to have port interfaces preserved.

`-sparse_modules` *`sparse_module_names`*

Specifies a list of module names to have sparse representations.

`-leaf_cells` *`leaf_cell_names`*

Specifies a list of cell reference names to be treated as leaf cells.

Feedback

`-buffer_cells` *buffer_cell_names*

Specifies a list of cell reference names to be treated as buffer cells.

`-macro_cells` *macro_cell_names*

Specifies a list of cell reference names to be treated as macro cells.

file_names

The names of one or more Verilog files to be read.

Description

Reads one or more structural, gate-level Verilog netlists into the tool as an outline design. An outline design is used for high capacity design planning. The outline design contains hierarchy, but no leaf cells or nets. An outline design cannot be used for optimization or timing.

After committing the design block hierarchy with the *commit_block* command, use the *expand_outline* command to expand each outline representation into a full design based on the original Verilog. It is important to keep the original Verilog files untouched in their original locations before you run the *expand_outline* command.

To enable Data Flow Analysis, top-level outline modules should contain dense netlist connectivity. Lower-level outline modules that don't need that information should contain sparse netlist connectivity. Use the *read_verilog_outline* command options to specify which modules should have a dense or sparse representation.

One of two methods are used to determine which modules are marked as dense or sparse. Use the partition method to create individual blocks of a specified hierarchical size. Use the allocation method to explore as much of the design hierarchy as possible within a memory budget of a maximum number of leaf cell instances. The default is the partition method. This can be changed with the *plan.outline.partition* app option.

For the partition method, top-level modules in the module hierarchy are marked as dense until the hierarchical cell count beneath a module is less than a target block size. Buffers and inverters are included in the hierarchical cell count. This maintains connectivity in the top levels of hierarchy which enables Data Flow Analysis. The target block size is specified by the *plan.outline.target_block_size* app option, which defaults to 1,000,000 leaf cells. Use the *-target_block_size* option to override the default setting.

In the partition method, after the partition blocks are designated, small module hierarchies within each partition are made dense. This maintains connectivity between the partition blocks for better Data Flow Analysis. The target number of leaf cells to allocate to these module hierarchies is specified by the *plan.outline.glue_cell_count* app option, which defaults to 100,000 leaf cells. A value of -1 skips marking any glue modules as dense. Buffers and inverters are not represented in the outline design and are not included in the target glue cell count. Use the *-glue_cell_count* option to override the default setting.

Feedback

For the allocation method, top-level modules in the module hierarchy are marked as dense until the target leaf cell count is reached. This count allows a rough trade-off between memory used for the outline design and the level of detail represented in the design. Buffers and inverters are not represented in the outline design and are not included in the target leaf cell count. The target leaf cell count is specified by the *plan.outline.target_cell_count* app option, which defaults to 1,000,000 leaf cells. Use the *-target_cell_count* option to override the default setting.

In the allocation method, modules that meet a leaf cell count threshold are considered large modules that should be represented as sparse modules in an outline design. Buffers and inverters are not represented in the outline design and are not included in the leaf cell count. The leaf cell count threshold is specified by the *plan.outline.large_threshold* app option, which defaults to 10,000 leaf cells. Use the *-large_threshold* option to override the default setting.

For Data Flow Analysis, dense connectivity is needed in top-level modules. The module hierarchy depth that should be marked as dense is specified by the *plan.outline.dense_module_depth* app option, which defaults to 1. Use the *-depth* option to override the default setting. A depth value of 1 forces the top module to be dense, a depth value of 2 forces the top module and its immediate children in the module hierarchy to be dense, and so on. A value of 0 has no effect. A value of -1 marks all non-sparse modules as dense. The hierarchy depth overrides the target cell count specified by the *-target_cell_count* option.

Modules and their parent modules in the module hierarchy up to the top module can be treated as dense modules by specifying their module names in the *-dense_modules* option list. The dense modules list overrides the target cell count specified by the *-target_cell_count* option.

Modules can be treated as sparse modules by specifying their module names in the *-sparse_modules* option list. Modules specified as sparse override all other options.

Dense modules have complete port interfaces, sparse modules do not. Use the *plan.outline.keep_port_depth* app option to specify the module hierarchy depth that should retain complete port interfaces. The default is 1. That value can be overridden with the *-keep_port_depth* option. A value of 0 or 1 retains the port interface of the top module. A value of 2 retains the port interface of the top module and its immediate children, and so on. A value of -1 retains the port interfaces for all modules.

Modules can be explicitly marked to retain their port interfaces by specifying their module names in the *-port_modules* option list.

The library's reference library list is examined to determine what cells are leaf cells. These cells are not instantiated into sparse modules, but they are counted so the area of each module can be computed. Buffer and inverter cells are not instantiated into sparse or dense modules, they are always counted so the area of each module can be computed. Large macro cells are important for design planning, so they are always instantiated.

Feedback

The *-leaf_cells* option can be used to specify the reference names of additional cells that should be treated as leaf cells and not instantiated into the sparse modules.

The *-macro_cells* option can be used to specify the reference names of additional cells that should be treated as macro cells and are always instantiated into the outline design.

In dense modules, netlist connectivity is mostly preserved. Inverters and buffer cells from the reference library are treated as wires so connections through those cells can still be seen, minus the buffers and inverters themselves.

The *-buffer_cells* option can be used to specify the names of additional cells that should be treated as wires connecting nets.

Nets and leaf cells are not represented in sparse modules. Leaf cells are counted so the area of each module can be computed. Sparse modules contain port interfaces only if a parent of the module is a dense module. Since a module must have a port interface to be committed as a block, make sure that modules which are block candidates have their port interfaces preserved.

Nets are still represented for flip_chip_driver cells even in sparse modules. When the flip_chip_driver cell is sparse, the module and the modules that contain them (up to the top) will be marked to retain their port interfaces, so there are nets to make the connections up to the top-level ports.

All port interfaces and nets are restored in the full design by the *expand_outline* command. Otherwise the *read_verilog_outline* command is similar to the *read_verilog* command. See the *read_verilog* command documentation for more information on options and variable settings.

Examples

In the following example, the r4000.v.gz compressed Verilog file is read into an outline design. The alu is committed as a separate block, and the top design is expanded.

```
prompt> set_ref_libs -ref_libs {"tcbn90ghvt" "tcbn90glvt"}
tcbn90ghvt tcbn90glvt
prompt> read_verilog_outline -top r4000 r4000.v.gz
Loading verilog file '/usr/.../r4000.v.gz'
1
prompt> current_design r4000
{"r4000"}
prompt> link
Information: units loaded from library 'tcbn90ghvt' (LNK-040)
Design 'r4000' was successfully linked.
1
prompt> commit_block alu
1
prompt> expand_outline
Loading verilog file './r4000.hcvr.v.gz'
```

Feedback

```

read_virtual_pad_file

Creates virtual pads from a file.

Syntax

status *read_virtual_pad_file*

```
file_name file_name
```

Data Types

```
file_name string
```

Arguments

```
file_name file_name
```

Specifies the file that contains virtual pad net names and locations.

Description

This command reads a file that contains net and coordinate information for virtual pads, and instantiates the virtual pads into the design.

The virtual pad file uses the following format, where the power net name is followed by lines containing x-coordinate, y-coordinate, and layer name for each pad location. You can also specify "auto" as the layer name.

```
power_net_name_a
x1 y1 layer_name1
x2 y2 layer_name2
```

Feedback

```
power_net_name_b
x3 y3 layer_name3
x4 y4 layer_name4
```

The following example assigns virtual pads for nets VDD and VSS.

```
VDD
1632.565  1183.195  auto
576.565   987.625   auto
1566.565  589.105   auto
675.565   1201.645  auto
1401.565  758.845   auto
VSS
1071.565  1365.565  auto
840.565   943.345   auto
708.565   1068.805  auto
1566.565  762.535   auto
```

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

Examples

The following example creates virtual pads from a file named test.vpad

```
prompt> read_virtual_pad_file test.vpad
```

See Also

- analyze_power_plan
- remove_virtual_pads
- report_virtual_pads
- set_virtual_pad
- write_virtual_pad_file

---

rebind_block

Rebind references in a block.

This command is deprecated, please use link_block command.

Syntax

int *rebind_block* [-verbose] [*block*]

```
string block
```

Feedback

Arguments

`-verbose`

The display verbose messages.

`block`

The block to be rebound; the default is the current block.

Description

Rebinds block references for the specified *block* or the current block using the library's ref_lib list.

Libraries specified in the ref_lib list are searched in order for references to physically hierarchical blocks and lib cells. The ref_lib list uses the *search_path* to locate libraries. The ref_lib list is usually set when the library is created with the *create_lib* command, but can be updated with the *set_ref_libs* command.

Unresolved Verilog references from *link_block* will be bound using the view switch list if the referenced block is now available in the ref_lib list.

The *rebind_block* command does not change the bound block view for each cell. To change the view referenced by a cell, use the *change_view* command.

Pins on each cell that reference the block are updated to match the ports on the referenced block. Pins can be added or deleted as needed. If a pin that is a candidate to be deleted has a net connection, the rebind fails for that cell. That block reference is left unbound and the cell is unchanged.

The operation of the *rebind_block* command is similar to the *link_design -rebind* command. The *rebind_block* command only rebinds one block, while the *link_design -rebind* command rebinds all blocks in the block hierarchy.

Unresolved References

Cells which fail to be rebound are left as unbound references. These references appear as leaf cells in the block. To resolve an unbound reference, update the library's ref_lib list or the *search_path* to include the library containing the desired referenced block, and rebind the block.

The number of unresolved references to have detailed error messages can be selected using the *link.reference_limit* app option. After this limit has been reached, a summary of the number of unresolved references is given. You can change this limit with the *set_app_options* command. Information on *rebind_block* app options is found on the *link_options* manual page.

Feedback

Rebind Errors

Missing block references or incompatible port references will cause *rebind_block* to fail. To correct these failures, update the ref_lib list or *search_path* and rebind the block.

Examples

In the following example, block TOP in library blockLib is linked to physically hierarchical blocks MID and BOT, and the lib cell library leafCellLib.

```
prompt> rebind_block -verbose TOP
Using libraries: designLib leafCellLib
Rebind: Collapsing hierarchy for cell 'u2/uMID'.
Rebind: Collapsing hierarchy for cell 'u1/u2/uMID'.
Rebind: Collapsing hierarchy for cell 'u1/uBOT'.
Rebind: Remapping pins on reference MID
Block 'TOP' was successfully rebound.
1
prompt> link_block -verbose
Using libraries: designLib leafCellLib
Visiting block tiny:TOP.design
Visiting block tiny:BOT.design
Visiting block tiny:MID.design
Expanding block tiny:TOP.design
Block 'TOP' was successfully linked.
1
prompt>

reconnect_fishbone_style_power_switch

Performs blockage-aware fishbone style power switch reconnection.

Syntax

```
collection reconnect_fishbone_style_power_switch
-sw_cells list_of_power_switch_names
-ctrl_pin_name library_control_pin_name
-ack_pin_name library_acknowledge_pin_name
```

Data Types

```
list_of_power_switch_names       list
library_control_pin_name         string
library_acknowledge_pin_name     string
```

Arguments

`-sw_cells list_of_power_switch_names`

Specifies power switch cell names which will be reconnected. The specified power switch cells must be connected by the *connect_power_switch -mode fishbone* command. This option is required.

`-ctrl_pin_name library_control_pin_name`

Specifies the control pin name for the power switch library cell. This option is required.

`-ack_pin_name library_acknowledge_pin_name`

Specifies the acknowledge pin name for the power switch library cell. This option is required.

Description

This command performs blockage-aware fishbone style reconnection for power switches which were connected by the *connect_power_switch -mode fishbone* command. This command detects long connections between power switches and reconnects the power switches to the nearest neighbors. This command will not reconnect the main trunk cells. It cannot handle multiple groups of power switches simultaneously and it cannot be called multiple times for the same group of power switches after *connect_power_switch -mode fishbone*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following is an example reconnects the power switches. The control pin is SLEEP, the acknowledge pin is SLEEPOUT.

```
prompt> reconnect_fishbone_style_power_switch -sw_cells $sw_names \\
   -ctrl_pin_name SLEEP -ack_pin_name SLEEPOUT
```

See Also

- connect_power_switch

---

record_layout_editing

This command records changes to the layout change for a restricted set of objects and writes the changes to a Tcl script file. It is only used for final tape-out DRC fixing.

Syntax

status *record_layout_editing*

```
-start | -stop
[-output file_name]
```

Data Types

```
file_name       string
```

Arguments

`-start`

Begins recording changes to the layout for the current design. Layout changes are recorded until you perform *record_layout_editing -stop* or close the design.

`-stop`

Stops recording of changes to the layout writes out the changes to the output file specified by the *-output* option. This option must be used together with the *-output* option.

`-output file_name`

Specifies the output Tcl file name into which to write the layout changes. The file contains changes from the point when *record_layout_editing -start* is run to current point. This option must be used together with the *-stop* option.

Description

This command records the layout changes and writes out the changes to a Tcl script file. You can source the Tcl script file to re-create the changes. It could help to realize the parallel layout editing of the design.

Feedback

Run *record_layout_editing -start* to begin recording layout changes. When you run *record_layout_editing -stop -output*, layout changes since you ran *record_layout_editing -start* are written out as Tcl commands to the specified file. If you run *record_layout_editing -start* and the tool is already recording layout changes, the tool issues a warning message, discards the previous recording, and begins a new recording. If you close design while recording layout changes, the tool issues a warning message and discards the recording.

Parallel Layout Editing using record_layout_editing

You can use the *record_layout_editing* command to record layout changes on individual design blocks, then reapply the combined changes to a master design copy. The basic flow of the technique is as follows:

```
1. Design the partition.
2. Deploy each layout partition to separated designers
3. Record the layout changes for each design with the following steps:
    1) record_layout_editing -start
    2) Edit the layout
    3) record_layout_editing -stop -output change.tcl
4. Collect each designer's record of changes and source the changes to
the original design one by one. Using this technique, the final design
 will
contain all the layout changes.
```

Supported Object Types

Only changes for objects in the top block will be saved. The supported object types are as the following:

- Shape
- Via
- Terminal
- Via_def

Supported Editing Operations for Recording

The supported layout editing operation includes only the following:

- Tcl commands for creating layout objects
- Tcl commands for removing layout objects
- Set attributes by using **set_attribute**
- GUI move and resize

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example records a layout editing session to remove shape RECT_32_0.

Feedback

```
prompt> record_layout_editing -start
prompt> remove_shapes RECT_32_0
prompt> record_layout_editing -stop -output change.tcl
```

See Also

- set_attribute
- remove_shapes

---

record_signoff_eco_changes

Records ECO changes for the incremental signoff ECO flow.

Syntax

int *record_signoff_eco_changes*

-start [-input *file_name*]

int *record_signoff_eco_changes*

-stop [-def] [-compress]

int *record_signoff_eco_changes*

-init [-def] [-compress]

Data Types

file_name PrimeTime ECO Tcl file

Arguments

`-start`

Start to record ECO changes if the recording is not started yet, or else it will error out. This option is mutually exclusive with the *-stop* and *-init* options.

`-input` *file_name*

Specify a Tcl file for signature check. This option works together with the *-start* option. The tool checks signoff ECO signature consistency between the Tcl file and the current block. If the signatures are inconsistent, or there is no signature inside design or Tcl file, the check fails and the command issues an error message and exits. If the check passed, this command will automatically source the Tcl file.

The Tcl file input is the PT-ECO Tcl file generated by PrimeTime ECO flow. The signature check provide one extra layer protection to make sure the PT-ECO Tcl file applied to the right block.

Feedback

`-stop`

Terminate the recording if recording mode is on and save necessary data to disk. This option is mutually exclusive with the *-start* and *-init* options.

`-init`

Terminate the recording if recording mode is on, and save the full design data to disk as an initial point for the incremental signoff ECO flow. This option is mutually exclusive with the *-start* and *-stop* options.

`-def`

Save the DEF file. This option is used with the *-stop* or *-init* option.

`-compress`

Save the DEF and Verilog files in compressed format if available. This option works with the *-stop* or *-init* option.

Description

The *record_signoff_eco_changes* command records and saves the design ECO changes for the incremental signoff ECO flow. The command can record cell, netlist and physical geometry changes, and save the ECO changes to disk for the current block.

Inside the tool session for incremental signoff ECO flow, the timing ECO commands are not limited to PT-ECO Tcl. You can provide timing ECO commands manually to update the design. However, the logical recording will be terminated automatically if functional ECO commands are issued in the flow.

The saved ECO changes are used to benefit StarRC and PrimeTime runtime for the multiple iterations of incremental signoff ECO flow. It will always save an information file and full NDM db. Full DEF file will be saved if the *-def* option is available. If the logical recording is terminated, or option *-init* is used, full Verilog file will be saved. Depending on the recording status, other design change files may be saved also. These files will be used by StarRC and PrimeTime internally inside the incremental signoff ECO flow and are not be user-readable. If the current block is closed before the recording is stopped, all recorded information is discarded.

Examples

The following example is to create an initial point for incremental signoff ECO flow:

```
prompt> record_signoff_eco_changes -init
```

The following example starts to record the design ECO changes.

```
prompt> record_signoff_eco_changes -start -input pt_eco.tcl
```

The following example saves the recorded ECO changes.

Feedback

```
prompt> record_signoff_eco_changes -stop
```

The following example is a simple incremental signoff ECO flow.

```
prompt> open_block LIB.ndm:BLOCK
prompt> record_signoff_eco_changes -start -input pt_eco.tcl
prompt> place_eco_cells
prompt> route_eco
prompt> record_signoff_eco_changes -stop
```

See Also

- place_eco_cells
- route_eco

---

recover_auto_save

Opens the auto-saved library of the current library.

Syntax

status *recover_auto_save*

Description

This command recovers and opens the auto-saved library of the current library. You can also recover and open the latest auto-saved library through the command option -recover of open_lib. The auto-saved library is recovered, opened and merged into the current or original library.

Examples

The following example recovers the auto-saved library to the current library.

```
prompt> report_auto_save
*******************************************************
Original Library : r4000

Auto-saved library path                : /slowfs/ndmdisk003/r4000_19142
Auto-saved library timestamp           : Wed Aug 14 01:56:21 2019
Auto-saved library size                : 2933585 bytes
Auto-saved library is_recovery_save    : false
Auto-saved library context             : creste_net

prompt> recover_auto_save
Information: Loading library file
 '/slowfs/ndmdisk003/r4000_19142' (FILE-007)
```

---

recover_rp_placement

Recover placement information for placed relative placement groups.

Syntax

```
int recover_rp_placement
rp_group_list | -all
-blockage
```

Data Types

```
rp_group_list     list or collection
```

Arguments

rp_group_list

Specifies a list of relative placement groups. The list may contain relative placement group names, patterns, or collections. A collection may be specified using the *get_rp_groups* command. This option is mutually exclusive with *-all*.

`-all`

Recovers placement information for all relative placement groups from the current block. This option is mutually exclusive with *rp_group_list*.

`-blockage`

Specifies that consider relative placement blockages too. Please note that the bounding box of the placement blockages is not recovered. The size of the relative placement blockage is used in recovering placement information of the relative placement groups.

Description

This command recovers placement information for the specified relative placement groups. The placement information includes the bounding box and placement status of the relative placement groups. Note that placement information cannot be recovered if the relative placement group is not placed or placement failed.

Feedback

Examples

The following example recovers placement information for relative placement group named "top_rp1" and "top_rp2".

```
prompt> recover_rp_placement { top_rp1 top_rp2 }
2
```

See Also

- create_rp_group

- remove_from_rp_group
- write_rp_groups

---

recycle_programmable_spare_cells

Recycles the removed ECO cells and converts them back to programmable spare cells (PSC). These PSC cells can be used to do PSC mapping afterward. This command is typically used in the freeze silicon ECO flow.

Syntax

status *recycle_programmable_spare_cells*

```
[-cells cell_objects]
[-lib_cells_for_filler_recovery lib_cells]
```

Data Types

cell_objects	collection
lib_cells	collection

Arguments

`-cells` *cell_objects*

Specifies that the spare cells come from removed ECO cells for recycling. The specified cells must have the psc_filler_is_used attribute set to true. If this option is not specified, the command recycles cells by collecting all available spare cells with the psc_filler_is_used attribute set to true from the set of removed ECO cells in the current design.

Feedback

`-lib_cells_for_filler_recovery` *lib_cells*

Specifies the programmable spare cell (PSC) filler library cells, The command uses only these library cells to fill and recover the unused space of the PSC cells after PSC recycling. If the option is disabled, the command uses all available PSC filler library cells in the reference libraries.

Description

The *recycle_programmable_spare_cells* command recycles the removed ECO cells and converts them back to PSC cells. These PSC cells can be used to do PSC mapping afterward.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example recycles the cells specified by the *-cells* option and converts them back to PSC cells.

```
prompt> recycle_programmable_spare_cells \\
        -cells [get_cells *_Spare]
```

See Also

- place_freeze_silicon

---

redirect

Redirects the output of a command to a file.

Syntax

string *redirect*

```
[-append] [-tee] [-file | -variable | -channel] [-compress]
[-bg]
[-max_cores number_of_cores]
target
{command_string}
```

Data Types

```
number_of_cores  integer
target           string
command_string   string
```

Feedback

Arguments

`-append`

Appends the output to *target*.

`-tee`

Like the Linux command of the same name, sends output to the current output channel as well as to the *target*.

`-file`

Indicates that *target* is a file name, and redirection is to that file. This is the default.

This option is mutually exclusive with the *-variable* and *-channel* options.

`-variable`

Indicates that *target* is a variable name, and redirection is to that Tcl variable.

This option is mutually exclusive with the *-file* and *-channel* options.

`-channel`

Indicates that *target* is a Tcl channel, and redirection is to that channel.

This option is mutually exclusive with the *-file* and *-variable* options.

`-compress`

Compress when writing to file.

If redirecting to a file, this option specifies that the output should be compressed as it is written. The output file is in a format recognizable by the Linux *gzip -d* command.

You cannot specify this option with the *-append* option.

`-bg`

Indicates that the redirected command or script executes in the background and in parallel with other foreground commands downstream.

When you run this command, the tool returns the process ID (PID) of the background process and then displays the shell prompt immediately to execute the next command.

The *redirect -bg* command supports only a limited set of commands; the tool issues an error message if you specify an unsupported command. To list the supported commands, use the *list_commands -bg* command. If the command or script includes a *redirect -bg* command, the *-bg* option is ignored.

Feedback

You can run at most two commands in the background. If there are already two *redirect -bg* commands running, additional *redirect -bg* commands are queued.

If you run the *exit* or *quit* command while background commands are running, the tool waits for all background commands to complete before exiting.

The *-bg* option must be used with the *-file* and *-max_cores* options. No other options are allowed.

`-max_cores` *`number_of_cores`*

Specifies the maximum number of CPU cores that can be used by multicore commands run within the *redirect -bg* command.

`target`

Indicates the target of the output redirection. This is either a file name, Tcl variable, or Tcl channel depending on the command arguments.

`command_string`

Specifies the command to execute. Intermediate output from this command, as well as the result of the command, are redirected to *target*. The *command_string* must be rigidly quoted with curly braces.

Description

The *redirect* command performs the same function as the traditional Linux-style redirection operators > and >>. However, it is more flexible because you can redirect multiple commands or an entire script.

By default, the redirected commands are run in the foreground. To run the redirected commands in the background, use the *-bg* option. In both cases, the *command_string* must be rigidly quoted (that is, enclosed in curly braces) for the operation to succeed.

Note that the builtin Tcl command *puts* does not respond to output redirection of any kind. Use the builtin *echo* command instead.

Behavior Without the *-bg* Option

When you use the *redirect* command without the *-bg* option,

- The *redirect* command returns an empty string.

  Screen output occurs only if errors occurred during execution of the *command_string* (other than opening the redirect file). When errors occur, a summary message is printed. See the examples.

  Although the result of a successful *redirect* command is the empty string, you can still get and use the result of the redirected command. Construct a *set* command in which you set a variable to the result of your command. Then, redirect the *set* command. The variable holds the result of your command. See the examples.

Feedback

- By default, output is redirected to a file.

  You can redirect the output to a Tcl variable by using the *-variable* option or to a Tcl channel by using the *-channel* option.

  You can send the output to the current output device as well as the redirect target by using the *-tee* option. See the EXAMPLES section for an example.

Behavior With the *-bg* Option

The *-bg* option enables parallel processing on multicore hardware for performance reasons. This command is targeted for post-update reporting, analysis, and design export commands.

When you use the *redirect* command with the *-bg* option,

- The command returns the PID of the background job instead of an empty string.
- You must redirect the output to a file; the *-bg* option cannot be used with other redirect targets.
- The maximum number of cores for the main session is reduced by the maximum number of cores used by the background jobs.
- You can use the *parallel_execute* command with the *redirect -bg* command to run jobs in parallel in the background.
- Changes made to the netlist or other data by commands executed in the background job are not brought back to the foreground job.

  Also, using commands in the background job that modify the netlist or other data can cause memory blow up in the child process.
- The background job cannot pass variables back to the foreground job.

  To pass variables from a background job to the foreground job, you must write the contents of the variables to a file in the background job, and then read that file in the foreground job.
- If you use the *change_names* command in the background, you must stop recording Formality setup information before running the *redirect -bg* command and use a new SVF file within the background job. Both the SVF files must be provided for formal verification.

Examples

In the following example, the output of the plus procedure is redirected. The echoed string and the result of the plus operation are in the output file. Notice that the result is not echoed to the screen.

Feedback

```
prompt> proc plus {a b} {echo "In plus" ; return [expr $a + $b]}
prompt> redirect p.out {plus 12 13}
prompt> exec cat p.out
In plus
25
```

In this example, a typo in the command creates an error condition. The error message indicates that you can use *error_info* to trace the error, but you should first check the output file.

```
prompt> redirect p.out {plus2 12 13}
Error: Errors detected during redirect
        Use error_info for more info. (CMD-013)
prompt> exec cat p.out
Error: unknown command 'plus2' (CMD-005)
```

This example shows how to use of the results from redirected commands. Because the result of the *redirect* command for a command that does not generate a Tcl error is the empty string, use the *set* command to trap the result of the command. For example, assume that there is a command to read a file that has a result of "1" if it succeeds, and "0" if it fails. If you redirect only the command, there is no way to know if it succeeded.

```
prompt> redirect p.out { read_a_file "a.txt" }
# Now what? How can I redirect and use the result?
```

If you set a variable to the result, you can use that result in the foreground process.

```
prompt> redirect p.out { set rres [read_a_file "a.txt"] }
if { $rres == 1 } {
  echo "Read ok!"
}
```

The *redirect* command is not limited to redirection of a single command. You can redirect entire blocks of a script with a single *redirect* command. This simple example with the *echo* command demonstrates this feature:

```
prompt> redirect p.out {
?         echo -n "Hello "
?         echo "world"
?       }
prompt> exec cat p.out
Hello world
prompt>
```

The *redirect* command allows you to tee output to the previous output device and also to redirect output to a variable. This simple example with the *echo* command demonstrates this feature:

```
prompt> set y "This is "
This is
prompt> redirect -tee x.out {
```

Feedback

```
            echo XXX
            redirect -variable y -append {
              echo YYY
              redirect -tee -variable z {
                echo ZZZ
              }
            }
          }
XXX
prompt> exec cat x.out
XXX
prompt> echo $y
This is YYY
ZZZ

prompt> echo $z
ZZZ
```

The following example demonstrates how to run a Tcl procedure and a Tcl script in the background by using the *redirect* command with the *-bg* option. The Tcl procedure and Tcl script can contain any of the commands supported by the *-bg* option.

```
prompt> set_host_options -max_cores 4
prompt> redirect -bg -max_cores 1 -file x.out {MyTclProc}
prompt> redirect -bg -max_cores 1 -file y.out {source y.tcl}
prompt> echo $z
ZZZ
```

The following example demonstrates how the *set_svf* command can be used within the *redirect -bg* command. If the reference design is from foo.v, to verify the netlist after the *redirect -bg* command, use both the compile.svf and redirect.svf SVF files. To verify the netlist after the *compile -incremental* command, use the compile.svf and compile_incr.svf SVF files.

```
prompt> set_host_options -max_cores 4
prompt> set_svf compile.svf
prompt> read_verilog foo.v
prompt> read_sdc foo.sdc
prompt> compile
prompt> set_svf -off
prompt> redirect -bg -max_cores 1 -file x.out \\
   {set_svf redirect.svf; change_names -rules verilog -hierarchy; ...}
prompt> set_svf compile_incr.svf
prompt> compile -incremental
ZZZ
```

---

redo

Redo the effects of one or more commands.

Syntax

```
int redo
[-levels num_levels | -marker marker_name | -all]
[-check_only]
[-silent]
```

Data Types

```
num_levels        int
marker_name       string
```

Arguments

`-levels num_levels`

Redoes the effects of the specified number of command levels.

`-marker marker_name`

Restores the system state to the point of creation of the marker with the specified name.

`-all`

Restores the system to the most recent available state in the command history.

`-check_only`

Causes the command to return the same status and messages it would otherwise return without actually performing the redo or changing anything.

`-silent`

Surpresses messages and a TCL error in the event of an error.

Description

This command redoes the effects of one or more previous database-changing commands, or "command levels". If the *-levels* option is used, then the specified number of command

Feedback

levels will be redone. It is an error to specify more levels than there are in the command history that are more recent than the current point.

If the *-marker* option is used, then the system state will be restored to that of when the specified marker was created. *marker_name* may be the user assigned or system generated name of the marker. This option would typically be used to restore the system to a user marker, which would have been created using the *create_undo_marker* command. It is an error to specify a marker that was created previous to the current point in the command history - for that case use the *undo* command instead.

If the *-all* option is used, then the system state will be restored to the latest available state in the command history. Note that this may not be the latest state that was originally undone from, as the execution of a new state-changing command earlier in the history will cause the subsequent redo history to be truncated.

If neither the *-levels*, *-marker*, or *-all* option is used, then this command will redo one command level.

The command returns the actual number of command levels redone or, if the *-check_only* option was used, that would have been redone without the *-check_only* option.

Examples

The following redoes one command level:

```
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> set_attribute $inst origin {100 300}
{U368}
prompt> get_attribute $inst origin
100.0000 300.0000
prompt> undo
1
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> redo
1
prompt> get_attribute $inst origin
100.0000 300.0000
```

The following returns the system to the most recent state:

```
prompt> create_undo_marker my_mrk
my_mrk
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> set_attribute $inst origin {200 400}
{U368}
prompt> set_attribute $inst origin {300 600}
{U368}
prompt> get_attribute $inst origin
```

Feedback

```
300.0000 600.0000
prompt> undo -marker my_mrk
2
prompt> get_attribute $inst origin
0.0000 0.0000
prompt> redo -all
2
prompt> get_attribute $inst origin
300.0000 600.0000
```

---

refine_placement

Performs incremental placement with congestion optimization.

Syntax

status *refine_placement*

```
[-effort very_low | medium | high]
[-congestion_effort low | medium | high]
[-perturbation_level low | medium | high]
[-coordinates bbox ]
```

Data Types

bbox rectangle

Arguments

`-effort very_low | low | medium | high`

Specifies the CPU effort level for coarse placement. If running very low effort it is advised to set the -congestion_effort to low. The default effort level is medium.

`-congestion_effort low | medium | high`

Specifies the effort level of congestion removal. The higher effort, the less attention is paid to other objects: timing, density and total wire-length. The default effort level is *medium*.

Feedback

`-perturbation_level low | medium | high`

Specifies the perturbation level for the placement to optimize congestion. Specifying *low* produces the least amount of movement from the placement. The higher the level specified, the more movement you might expect from the placement. So, specifying *high* produces the most movement from the placement. The default effort level is *medium*.

`-coordinates` *bbox*

Specifies one rectangle that defines the region from which to run incremental congestion removal.

The "bbox" is lower-left and upper-right coordinates of a rectangle.

The default (without this option) is to run incremental placement for the entire design, which is the recommended way to use this command. If you want to specify one localized region on which incremental placement should be done, you can use this option to prevent any disturbance of the rest of the converged design. The region based refinement may cause timing/congestion degradation if regions are not properly specified.

The units of the *-coordinates* are in microns.

No runtime improvement is expected when this option is used; it is primarily used to restrict the placer from making changes outside the specified rectangles.

Description

The *refine_placement* command performs incremental congestion optimization for the current design. This command does not touch netlist.

Multicorner-Multimode Support

This command operates a scenario selected based on timing QoR.

Examples

The following example runs the *refine_placement* command in low-effort congestion mode:

```
prompt> refine_placement -congestion_effort low
```

The following example runs the *refine_placement* command in single region:

```
prompt> refine_placement -coordinates { {$llx1 $lly1} { $urx1 $ury1 } }
```

See Also

- create_placement

Feedback

refine_topology_plans

Refines a topology plan to create additional nodes and edges.

Syntax

int *refine_topology_plans*

`[topology_plan_list]`

Data Types

`topology_plan_list  collection`

Arguments

`topology_plan_list`

Specifies the list of topology plans to refine. If unspecified, all the topology plans within the current design are refined.

Description

The *refine_topology_plans* command refines a topology plan by creating additional nodes and edges.

If a topology edge has layer-shapes attribute defined with Manhattan-style edge segments, new topology nodes are created where the edge segments cut at block boundaries. The original topology edge is also cut at the position where the new topology nodes are created, and new topology edges are created between new and existing topology nodes, and then connect them together.

If the topology edge does not have the layer-shapes attribute defined or the layer-shapes are not Manhattan style, then no new nodes or edges are created for this topology edge.

Upon success, the command returns 1; otherwise, 0.

Examples

The following example refines all the topology plans of the design.

```
prompt> refine_topology_plans
```

The following example refines a specific topology plan, A2B.

```
prompt> refine_topology_plans [get_topology_plans A2B]
```

refresh_performance_via_ladder_constraints

Refreshes via ladder constraints in a design to ensure compliance with via ladder candidates.

Feedback

Syntax

status *refresh_performance_via_ladder_constraints*

Description

The *refresh_performance_via_ladder_constraints* command refreshes via ladder constraints in a design to ensure compliance with via ladder candidates.

Examples

The following example verifies all via ladder constraints in the design and updates via ladder constraints which comply with via ladder candidates.

```
prompt> refresh_performance_via_ladder_constraints
```

See Also

- insert_via_ladders
- refresh_via_ladders
- remove_via_ladder_constraints
- remove_via_ladders
- set_via_ladder_constraints
- verify_via_ladders

---

refresh_via_ladders

Refreshes via ladders to ensure compliance with via ladder constraints. This command runs the *verify_via_ladders* command, removes any via ladders that would cause "Misplaced via ladder" DRCs, and runs the *insert_via_ladders* command to insert via ladders where needed. The command is further controlled with the route.auto_via_ladder.* application options.

Syntax

status *refresh_via_ladders*

```
[-nets {collection_of_nets}]
[-pins {collection_of_pins}]
```

Data Types

```
collection_of_nets  collection
collection_of_pins  collection
```

Feedback

Arguments

`-nets {collection_of_nets}`

Specifies the nets on which to update via ladders. A via ladder will be updated only on pins with via ladder constraints when the pin is also on one of the specified nets.

If you do not specify this option, via ladders are updated on any pin with a via ladder constraint.

`-pins {collection_of_pins}`

Specifies the pins on which to insert via ladders.

Description

The *refresh_via_ladders* command refreshes via ladders in a design to ensure compliance with via ladder constraints. This command runs the *verify_via_ladders* command, removes any via ladders that would cause "Misplaced via ladder" DRCs, and runs the *insert_via_ladders* command to insert via ladders where needed.

The *route.auto_via_ladder.update_during_route* application option, when true, activates an automatic via ladder update at the start of all routing commands that run global routing, track assignment, and detail routing. This includes the *route_auto*, *route_group*, and *route_eco* commands.

The *refresh_via_ladders* command executes the same internal flow as automatic via ladder updating in routing commands, but does so as a standalone command. The *refresh_via_ladders* command performs the via ladder update and terminates immediately without performing any other routing tasks.

Examples

The following example verifies all via ladders in the design, removes any via ladders that cause "Misplaced via ladder DRCs," and performs via ladder insertion. Vias ladders are inserted on any pin with a via ladder constraint but no corresponding via ladder in the layout.

```
prompt> refresh_via_ladders
```

---

remove_3d_virtual_blocks

Removes virtual interface blocks.

Syntax

integer *remove_3d_virtual_blocks*

```
-all | vib | vib_cell | {die1 die2}
```

Data Types

```
vib         collection
vib_cell    collection
die1        collection
die2        collection
```

Arguments

`-all`

Removes all virtual interface blocks in the design.

vib

Specifies the virtual interface block to remove.

vib_cell

Specifies the virtual interface block by cell instance to remove.

{ die1 die2 }

Specifies the dies between which to remove the virtual interface block.

Description

This command removes virtual interface blocks from the design. If the virtual interface block was connected to the top netlist during creation, the die ports at the interface are reconnected back together.

Examples

The following example removes all virtual interface blocks from the design.

```
prompt> remove_3d_virtual_blocks -all
```

The following example removes the virtual interface block between two dies.

```
prompt> remove_3d_virtual_blocks {die1 die2}
```

Feedback

The following example removes the specified virtual interface block.

```
prompt> remove_3d_virtual_blocks die1__die2
```

See Also

- create_3d_virtual_blocks

---

remove_abstract

Removes the abstract associated with the given design from memory and disk

Syntax

```
return_val remove_abstract
[design_name]
```

Data Types

```
return_val        0 (or 1) if command failed (or succeeded).
design_name       Name in form [libName:]designName/label
```

Arguments

design_name

The source design name with optional library specifications. If the option is not given, the *current_design* is used. If the library specification is not given, the *current_lib* is used. The library of the specified block should already be opened in edit mode.

Returns

Returns 1 if the design is saved and 0 if not. If an illegal name(with a slash) is given for the design, a TCL error is raised.

Description

The command removes the abstract view associated with the given (or current) design. If the abstract is editable, the open blocks on which the abstract depends will automatically be upgraded to "edit" mode.

Examples

Remove the abstract view associated with the current design.

```
prompt> remove_abstract
1
```

Following example removes the abstract associated with the design "mid", in library "midlib".

Feedback

```
prompt> list_blocks
Lib toplib
  +>  0 top.design current
Lib midlib
  ->  0 mid.abstract
  -   0 mid.design
3
prompt> remove_abstract midlib:mid
1
prompt> list_blocks
Lib toplib
  +>  0 top.design current
Lib midlib
  ->   0 mid.design
2
```

See Also

- create_abstract
- merge_abstract

---

remove_alignment_marker_rules

Removes the specified alignment marker rules.

Syntax

status *remove_alignment_marker_rules*

```
[-design design]
[-all]
[alignment_marker_rule_list]
```

Data Types

design	string
alignment_marker_rule_list	collection

Arguments

`-design design`

Specifies the design in which to remove the alignment marker rule(s). If no design is specified, the alignment marker rule(s) are removed from the current design.

`-all`

Removes all the alignment_marker_rule objects defined in the current design.

Feedback

alignment_marker_rule_list

Specifies the rule objects or names, which need to be removed.

Description

Removes the specified rule objects from the current design. It also deletes the cell(s) associated with the alignment_marker_rule(s) being deleted.

Examples

The following example collects collection of alignment_marker_rule objects and then deletes them.

```
prompt> remove_alignment_marker_rules [get_alignment_marker_rules rule1*]
```

The following example deletes all the alignment_marker_rule objects from design "design1".

```
prompt> remove_alignment_marker_rules -design design1 -all
```

See Also

- create_alignment_marker_rule
- get_alignment_marker_rules

---

remove_anchors

Removes anchors from the current block.

Syntax

int *remove_anchors*

```
[-all]
[-verbose]
[anchor_list]
```

Data Types

anchor_list list

Arguments

-all

Removes all anchors from the current block.

Feedback

`-verbose`

Displays verbose deletion information.

`anchor_list`

Specifies a list of anchors to remove. The list can contain anchor names, patterns, or collections. A collection can be specified by using the *get_anchors* command.

Description

This command removes anchors from the current block.

Examples

The following example removes anchors that match the pattern "anchor*".

```
prompt> remove_anchors anchor*
3
```

The following example removes all anchors in the block.

```
prompt> remove_anchors -all
5
```

See Also

- get_anchors
- create_anchor

---

remove_annotated_check

Removes annotated timing-check information.

Syntax

status *remove_annotated_check*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
-all | -from from_list | -to to_list
[-rise | -fall]
[-clock rise | fall]
[-setup]
[-hold]
[-recovery]
[-removal]
[-nochange_low]
[-nochange_high]
```

Feedback

```
[-width]
[-period]
```

Data Types

```
from_list      list
to_list        list
```

Arguments

`-modes` *mode_list*

Specifies the modes for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the *-scenarios* option.

`-corners` *corner_list*

Specifies the corners for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the *-scenarios* option.

`-scenarios` *scenario_list*

Specifies the scenarios for which to remove the annotated value. Each of the specified scenarios is de-annotated separately. It is an error to give this option with the *-modes* or the *-corners* options. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command applies to the current scenario only.

`-all`

Removes all annotated checks in the current design. This includes rise and fall values for setup, hold, recovery, removal, and nochange pin-to-pin timing checks. You must specify either *-all*, *-from*, or *-to*; if you specify *-all*, you cannot specify any other arguments or options.

`-from` *from_list*

Specifies a list of leaf cell clock pins that are the startpoints of the timing arcs from which annotated checks are to be removed. You must specify either *-all*, *-from*, or *-to*; if you specify *-all*, you cannot specify any other arguments or options.

Feedback

`-to` *`to_list`*

Specifies a list of leaf cell data pins that are the endpoints of the timing arcs from which annotated checks are to be removed. You must specify either *-all*, *-from*, or *-to*; if you specify *-all*, you cannot specify any other arguments or options.

`-rise | -fall`

Specifies whether the check to be removed is for data rise or fall transition. If you do not specify either *-rise* or *-fall*, both values are removed.

`-clock rise | fall`

Specifies whether the check to remove is for clock rising or falling. By default, checks for both clock rise and fall are removed.

`-setup`

Removes only setup timing-check information.

`-hold`

Removes only hold timing-check information.

`-recovery`

Removes only recovery timing-check information.

`-removal`

Removes only removal timing-check information.

`-nochange_low`

Removes only the nochange timing check against data low information.

`-nochange_high`

Removes only the nochange timing check against data high information.

`-width`

Removes only minimum pulsewidth timing check information.

`-period`

Removes only period timing check information.

Description

This command removes annotated timing checks between the specified pins. Data rise and fall and clock rise and fall annotated checks are removed by default.

You can use the *remove_annotated_check* command for pins at lower levels of the design hierarchy. These pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

If the design is not already linked, *remove_annotated_check* links it automatically.

Feedback

The *remove_annotated_check* command removes annotated timing checks set by the *set_annotated_check* command, and also removes setup, hold, recovery, removal, or nochange annotated timing checks set by the *read_sdf* command. The *reset_design* command removes annotated timing checks in addition to other information.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example removes an annotated setup check between pins u1/u2/CP and u1/u2/D:

```
prompt> remove_annotated_check -setup -from u1/u2/CP -to u1/u2/D
```

The following example removes all annotated timing checks on the current design:

```
prompt> remove_annotated_check -all
```

See Also

- current_design
- report_annotated_check
- reset_design
- set_annotated_check

---

remove_annotated_delay

Removes the annotated delay between two pins.

Syntax

status *remove_annotated_delay*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
-all | -from from_list | -to to_list
```

Data Types

```
from_list     list
to_list       list
```

Feedback

Arguments

`-modes` *`mode_list`*

Specifies the modes for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the *-scenarios* option.

`-corners` *`corner_list`*

Specifies the corners for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the *-scenarios* option.

`-scenarios` *`scenario_list`*

Specifies the scenarios for which to remove the annotated value. Each of the specified scenarios is de-annotated separately. It is an error to give this option with the *-modes* or the *-corners* options. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command applies to the current scenario only.

`-all`

Removes all net- and cell-annotated delays in the current design. If you specify *-all*, you cannot specify any other arguments.

`-from` *`from_list`*

Specifies a list of leaf-cell pins or top-level ports that are the startpoints of the timing arcs from which to remove annotated delays. You must specify either *-all*, or both *-from* and *-to*.

`-to` *`to_list`*

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs from which to remove annotated delays. You must specify either *-all*, or both *-from* and *-to*.

Description

This command removes annotated delays between the specified pins, which must be on the same net or on the same cell. Both rise and fall annotated delays are removed. There must be a timing arc between the pins in *from_list* and the pins in *to_list* or no annotated delay is removed.

You can use *remove_annotated_delay* for pins at lower levels of the design hierarchy. These pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

Feedback

To annotate net delay values between pins in a design, use *set_annotated_delay -net* command. To annotate cell delay values between pins in a design, use the *set_annotated_delay -cell* command. You must use *-from* and *-to* in the same manner you used them to set annotated values.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example first shows the annotation of the delay to remove. The second command removes the annotated net delay between output pin Z of cell instance U1/U2/U3 and input pin A of cell instance U6:

```
prompt> set_annotated_delay -net <value> -from U1/U2/U3/Z -to U6/A
prompt> remove_annotated_delay -from U1/U2/U3/Z -to U6/A
```

The following example removes all annotated net and cell delays from the current design:

```
prompt> remove_annotated_delay -all
```

See Also

- current_design
- report_timing
- reset_design
- set_annotated_delay

---

remove_annotated_power

Removes annotated cell power dissipation values that were set by *set_annotated_power*.

Syntax

status *remove_annotated_power*

```
-scenarios scenario_list
-all
[cell_list]
```

Data Types

```
scenario_list       list
cell_list       list
```

Feedback

Arguments

`-scenarios`

Specifies the set of scenarios for which the annotated values should be removed. The default is the value returned by the *current_scenario* command.

`-all`

Specifies that the power annotations of all cells should be removed.

`cell_list`

Specifies the cells for which the annotated power values should be removed. When option *-all* is given, no cell_list is allowed.

Description

This command removes annotated power values on cells. These annotations were previously applied using the *set_annotated_power* command. The command removes all annotations of a cell, so both leakage and internal power annotations for all supply nets are removed.

Examples

The following example removes the power annotations for cell U1/U2/U3 in the current scenario.

```
prompt> remove_annotated_power U1/U2/U3
```

The following example removes the power annotations of all cells in the scen1 scenario.

```
prompt> remove_annotated_power -all -scenarios scen1 \\
```

See Also

- report_annotated_power
- set_annotated_power

---

remove_annotated_transition

Removes the annotated transition at a pin.

Syntax

status *remove_annotated_transition*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
-all | pins
```

Feedback

Data Types

pins collection

Arguments

-modes *mode_list*

Specifies the modes for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified corner(s). It is an error to give this option with the *-scenarios* option.

-corners *corner_list*

Specifies the corners for which to remove the annotated value. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is de-annotated separately. If this option is not given, the command removes annotation for every scenario that is active with the specified mode(s). It is an error to give this option with the *-scenarios* option.

-scenarios *scenario_list*

Specifies the scenarios for which to remove the annotated value. Each of the specified scenarios is de-annotated separately. It is an error to give this option with the *-modes* or the *-corners* options. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command applies to the current scenario only.

-all

Removes the annotated transition time from every pin in the current design. If you specify *-all*, you cannot specify any other arguments.

pins

Removes the annotated transition time from the specified pins. If you specify *-all*, you cannot specify any other arguments.

Description

This command removes annotated transitions at the specified pins. Both rise and fall annotated transitions are removed.

To annotate net-transition values at pins in a design, use the *set_annotated_transition* command.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Feedback

Examples

The following example removes the annotated transition at every pin in the design:

```
prompt> remove_annotated_transition -all
```

The following example first shows the annotation of the transition to be removed. The second command removes the annotated transition at the output pin Z of cell instance U1/U2/U3:

```
prompt> set_annotated_transition value U1/U2/U3/Z
prompt> remove_annotated_transition U1/U2/U3/Z
```

See Also

- current_design
- report_timing
- reset_design
- set_annotated_transition

---

remove_annotation_shapes

Removes annotation_shapes.

Syntax

int *remove_annotation_shapes*

```
[-all]
[-verbose]
[annotation_shape_list]
```

Data Types

annotation_shape_list list

Arguments

`-all`

Removes all annotation_shapes from the current block.

`-verbose`

Displays verbose deletion information.

Feedback

annotation_shape_list

Specifies a list of annotation_shapes to remove. The list may contain annotation_shape names, patterns, or collections. A collection may be specified by using the *get_annotation_shapes* command.

Returns

The number of removed annotation_shapes.

Description

This command removes annotation_shapes from the current block. All annotation_points owned by the removed annotation_shapes are also removed.

Examples

The following example removes annotation_shapes that match the pattern "ANNOTATION_SHAPE*".

```
prompt> remove_annotation_shapes ANNOTATION_SHAPE*
3
```

The following example removes all annotation_shapes in the block.

```
prompt> remove_annotation_shapes -all
5
```

See Also

- get_annotation_shapes

---

remove_antenna_rules

Name

remove_antenna_rules

Removes the antenna rules in the library.

Syntax

```
integer remove_antenna_rules
[-mode antenna_mode]
[-name rule_name]
[-library library]
```

Data Types

```
antenna_mode  integer
rule_name     string
library       collection
```

Feedback

Arguments

`-mode` *`antenna_mode`*

An integer value between 1 and 6, that represents the way the antenna areas are computed. When this option is specified, only the antenna rules that use the given mode for antenna area calculation, are updated to remove the specified mode. This is an optional option and mutually exclusive to *-name*.

`-name` *`rule_name`*

The name of the antenna rule to be deleted from the given library. The command aborts if an antenna rule with the given name does not exist. This is an optional option and mutually exclusive to *-mode*.

`-library` *`library`*

The library from which the given antenna rules are to be deleted. This is an optional option. When not specified, the antenna-rules from the current library are deleted.

Description

This command removes the antenna rules from the given library. The default behavior is to remove all the antenna rules from the current library.

The command returns the number of antenna rules removed from the given library when all rules are removed. It returns 1 when a rule is removed based on a specified name or when a mode is removed from corresponding rules.

Examples

The following example removes the antenna rule 'r1' from the current library.

```
prompt>remove_antenna_rules -name r1
1
```

The following example removes all the antenna rules from the library 'lib1'

```
prompt>remove_antenna_rules -library lib1
16
```

See Also

- define_antenna_rule
- define_antenna_layer_rule
- get_antenna_rule_names
- report_antenna_rules

Feedback

remove_array_from_macro_group

Remove macro array to macro group.

Syntax

```
status remove_array_from_macro_group macro_array
```

Data Types

```
macro_array   ndm edit group for macro array
```

Arguments

```
-macro_array macro_array
```

Specifies macro array.

Description

This command remove specified macro array from the macro group it belongs to. All macros of the macro array will be removed from the macro group.

Examples

The following command remove macro array array1 from its macro group.

```
prompt> remove_array_from_macro_group -array array1
```

See Also

- add_macro_to_group
- remove_macros_from_group
- clone_macro_group_packing
- create_macro_array

remove_attachments

Removes the given attachments from the specified owner object.

Syntax

status *remove_attachments*

```
names
[-of_object objects]
```

Feedback

Data Types

```
names    list
objects  collection
```

Arguments

names

List of attachment names to be removed. This argument supports glob style patterns.

`-of_object` *objects*

Specifies the object whose attachments will be removed. By default, the current block and current library will be considered in that order as owner object.

Description

This command removes the attachments with the names in the given list from the objects provided through the *-of_object* option. If *-of_object* is not used, then the current block is used as the owner object. If current block is not set, current library is used as the owner object For the attachment names, glob style pattern is supported.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes the attachment test_attachment from the current block.

```
prompt> remove_attachments -of_object [current_block] test_attachment
1
```

See Also

- add_attachment
- open_attachment
- report_attachments

---

remove_attributes

Removes an attribute from the specified objects.

Syntax

collection *remove_attributes*

Feedback

```
[-quiet]
-objects object_list
-name attribute_name
pos_object_list
pos_attribute_name

object_list           list
attribute_name        string
pos_object_list       list
pos_attribute_name    string
```

Arguments

`-quiet`

Turns off the warning messages that would otherwise be issued if the attribute or objects are not found.

`-objects object_list`

Specifies a list of objects from which the attribute is to be removed. Each element in the list is a collection of objects. This option is mutually exclusive with *pos_object_list*. Either one (and only one) of *-objects* or *pos_object_list* must be specified.

`-name attribute_name`

Specifies the name of the attribute to be removed. This option is mutually exclusive with *pos_attribute_name*. Either one (and only one) of *-name* or *pos_attribute_name* must be specified.

pos_object_list

Specifies a list of objects from which the attribute is to be removed. Each element in the list is a collection of objects. This positional option is provided for compatibility with other tools.

pos_attribute_name

Specifies the name of the attribute to be removed. This positional option is provided for compatibility with other tools.

Description

This command removes the specified attribute from the specified objects. This command returns a collection of objects that have the specified attribute removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the attributes. However, for attributes such as *max_leakage_power*, which are scenario dependent, this command uses information from the current scenario only.

Feedback

Examples

The following command defines a new attribute named *X* on the net:

```
prompt> define_user_attribute -type int -classes net -name X
1
```

The following command sets the *X* attribute to 30 on all the nets in the current hierarchy:

```
prompt> set_attribute -objects [get_nets *] -name X -value 30
{"out", "in", "VDD", "VSS"}
```

This command removes the *X* attribute from the nets named *VSS* and *VDD*:

```
prompt> remove_attributes -objects [get_nets V*] -name X
{"VDD", "VSS"}
```

This command retrieves the *X* attribute from the net named *VDD*:

```
prompt> get_attribute -objects [get_nets VDD] -name X
Warning: Attribute 'X' does not exist on net 'VDD' (ATTR-3)
```

The following command retrieves the *X* attribute from a net named *in*;

```
prompt> get_attribute -objects [get_nets in] -name X
30
```

This command removes the *output_not_used* attribute on a port:

```
prompt> remove_attributes -objects [get_ports OUT1] -name output_not_used
{"OUT1"}
```

In the following example, a warning message is issued because the cell named *U9* cannot be found:

```
prompt> remove_attributes -objects [get_cells {U1 U9}] -name dont_touch
Warning: No cell objects matched 'U9' (SEL-004)
{"U1"}
```

In the following example, the specified attribute cannot be found:

```
prompt> remove_attributes -objects [get_cells *] -name arrival
Warning: Attribute 'arrival' has not been defined for cells (ATTR-1)
```

---

remove_auto_save

Removes the auto-saved library of the specified library.

Syntax

status *remove_auto_save*

```
[-library library_name | library_path]
```

Data types

```
library_name                string
library_path                string
auto_saved_library_name     string
```

Arguments

`-library`

Specifies the library name or path whose auto-saved library needs to be removed.

Description

This command removes the specified auto-saved library of the specified library. By default, this command removes the auto-saved library of the current library.

Examples

The following example removes the auto-saved library of the current library.

```
prompt> remove_auto_save
```

See Also

- stop_auto_save
- recover_auto_save
- start_auto_save
- report_auto_save

Feedback

remove_blackbox_timing

Removes black box timing data and updates the abstract view for the current block.

Syntax

```
status remove_blackbox_timing
```

Arguments

This command has no arguments.

Description

This command removes the black box timing information on the current block. The abstract view of the current block is updated or re-created to reflect the change.

Examples

The following example creates an abstract view with black box timing information for the current design, and then updates the abstract view to remove BBT data.

```
prompt> create_clock -period 10 -name main_clock [get_ports Clk]
prompt> set_blackbox_clock_port Clk
prompt> create_blackbox_load_type -lib_cell buf0 loadType1
prompt> create_blackbox_drive_type -lib_cell buf8 driveType1
prompt> set_blackbox_port_load -type loadType1 [all_inputs]
prompt> set_blackbox_port_drive -type driveType1 [all_outputs]
prompt> create_blackbox_delay -rise_from Clk -to [all_outputs] -clock
 main_clock -value 0.3
prompt> create_blackbox_constraint -from Clk -edge rise -to [all_inputs]
 \\
        -clock main_clock -value 0.3
prompt> commit_blackbox_timing
prompt> remove_blackbox_timing
```

See Also

- commit_blackbox_timing

remove_block_pin_constraints

Removes the existing block pin constraints.

Syntax

string *remove_block_pin_constraints*

```
[-cells cell_collection]
[-self]
```

Feedback

```
[-pin_spacing_control]
[block_pin_constraints]
```

Data Types

```
cell_collection       collection
block_pin_constraints collection
```

Arguments

`-cells` *cell_collection*

Specifies the blocks from which to remove block pin constraints. If you specify this option, the command only removes the block pin constraints for the specified blocks.

If you do not specify this option and the "-self" option, the command removes block pin constraints for all blocks inside current design.

`-self`

If this option is specified, the command removes the block pin constraints that are associated with current top design.

`-pin_spacing_control`

If this option is specified, the command removes the block pin spacing constraints that are set by read_pin_constraints and associated with reference blocks.

block_pin_constraints

Specifies the block_pin_constraint objects to remove. The list can be a collection of block_pin_constraints or name patterns. A collection might be specified by using the *get_block_pin_constraints* command. When this option is used, the number of removed block_pin_constraint objects is returned. This option is mutually exclusive with the -cell, -self, and -pin_spacing_control options.

Description

This command removes block pin constraints from blocks. If you specify the -cell, -self, -pin_spacing_control, or no options, this command removes pin constraints for all blocks. If you specify the block_pin_constraints option, this command removes the specified block_pin_constraint objects from the current block.

The *set_editability* command can enable or disable the *remove_block_pin_constraints* command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the *set_editability* command.

Examples

The following example removes the physical constraints for all pins, nets and blocks.

Feedback

```
prompt> remove_block_pin_constraints
```

The following example removes the block_pin_constraint object from the current block.

```
prompt> remove_block_pin_constraints *
1
```

See Also

- report_block_pin_constraints
- set_block_pin_constraints
- create_block_pin_constraint
- get_block_pin_constraints
- set_editability

---

remove_blocks

Removes one or more open blocks from memory, its library, and the disk.

Syntax

```
return_val remove_blocks
[-force]
blocks
```

Data Types

```
return_val      0 (or 1) if command failed (or succeeded)
blocks          A single block name in
 [libName:]blockName[/labelName][.viewName] format or
        a collection of blocks
```

Arguments

`-force`

This option is used when the destination is (or may be) open and modified but not yet saved.

`blocks`

A block name with optional library, label, and view specifications, or a collection of blocks. If the library specification is not present, the *current_lib* is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then *design view* is used. If the option is not given, the *current_block* is used. When no view is explicitly specified then all available views are considered.

Feedback

Returns

Returns the number of blocks removed and 0 if not. If an illegal name(with a slash) is given for the block, a Tcl error is raised.

Description

This command removes an open block and all of its contents. After it is executed the block is purged from memory and its disk contents are removed. USE THIS COMMAND WITH EXTREME CAUTION! It is intended for use primarily in scripts that (re)construct blocks at the beginning to reinitialize a block completely from scratch. The command will fail if the block has been modified but not yet saved unless the *-force* option is given. Note that this command works if a block exists whether it is in memory or not.

When no view is explicitly specified for *blocks* then all available views of source block are removed.

Examples

This example forcibly removes the block Top from both memory and from disk.

```
prompt> remove_blocks -force Top
1
```

---

remove_bond_pad_defs

Removes bond pad definitions from the current design.

Feedback

Syntax

status *remove_bond_pad_defs*

```
[def_list]
[-all]
```

Data Types

```
def_list      collection
```

Arguments

def_list

Specifies a list of bond pad definitions to remove. The list might contain definition collections specified using the *get_bond_pad_defs* command.

This option is mutually exclusive with *-all* option.

`-all`

Removes all bond pad definitions from the current design.

This option is mutually exclusive with *def_list* option.

Description

This command removes all specified bond pad definitions related to the current block.

Either *def_list* or *-all* must be specified.

Examples

The following example removes bond pad definition def_1.

```
prompt> remove_bond_pad_defs [get_bond_pad_defs def_1]
1
```

See Also

- create_bond_pad_def
- get_bond_pad_defs

---

remove_bound_shapes

Removes bound shapes from the current design.

Syntax

int *remove_bound_shapes*

Feedback

```
[-verbose]
[-all]
[-force]
[bound_shape_list]
```

Data Types

```
bound_shape_list     list
```

Arguments

`-verbose`

Displays verbose deletion information.

`-all`

Removes all bound shapes and their owning move bounds from the current design.

`-force`

Ignore locked status of the objects. If this option is not provided and any of the affected objects has locked status, command will fail generating tcl error.

bound_shape_list

Specifies a list of bound shapes to remove. The list may contain bound shape collections, specified using the *get_bound_shapes* command.

Description

This command removes bound shapes from the current design except macro group move bound's bound shapes. If all bound shapes of a particular move bound is removed, the move bound is removed as well.

Macro group move bound's shapes cannot be removed using this command. To remove bound shapes from macro group move bound use remove_bound to completely remove the bound followed by create bound to create the macro_group move bound with desired bound shapes.

The number of removed bound shapes are returned.

Examples

The following example removes bound shapes of bound "movebound1".

```
prompt> remove_bound_shapes [get_bound_shapes -of_objects movebound1]
2
```

The following example removes all bound shapes in the design.

```
prompt> remove_bound_shapes -all
5
```

Feedback

---

remove_boundary_cell_rules

Removes the boundary cell insertion and checking rules.

Syntax

status *remove_boundary_cell_rules*

```
[-all]
[-left_boundary_cell]
[-right_boundary_cell]
[-bottom_boundary_cells]
[-top_boundary_cells]
[-bottom_left_outside_corner_cell]
[-bottom_right_outside_corner_cell]
[-top_left_outside_corner_cell]
[-top_right_outside_corner_cell]
[-bottom_left_inside_corner_cells]
[-bottom_right_inside_corner_cells]
[-top_left_inside_corner_cells]
[-top_right_inside_corner_cells]
[-mirror_left_outside_corner_cell]
[-mirror_right_outside_corner_cell]
[-mirror_left_inside_corner_cell]
[-mirror_right_inside_corner_cell]
[-mirror_left_boundary_cell]
[-mirror_right_boundary_cell]
[-mirror_left_inside_horizontal_abutment_cell]
[-mirror_right_inside_horizontal_abutment_cell]
[-tap_distance]
[-top_tap_cell]
[-bottom_tap_cell]
[-prefix]
[-separator]
[-insert_into_blocks]
[-at_va_boundary]
```

Feedback

```
[-no_1x]
[-min_row_width]
[-min_horizontal_jog]
[-min_vertical_jog]
[-min_horizontal_separation]
[-min_vertical_separation]
[-do_not_swap_top_and_bottom_inside_corner_cell]
[-allow_protrusive_inside_corner_cell]
```

Arguments

`-all`

Specifies whether to remove all the existed boundary cell rules.

`-left_boundary_cell`

Specifies whether to remove the existed left boundary cell rule.

`-right_boundary_cell`

Specifies whether to remove the existed right boundary cell rule.

`-bottom_boundary_cells`

Specifies whether to remove the existed bottom boundary cells rule.

`-top_boundary_cells`

Specifies whether to remove the existed top boundary cells rule.

`-bottom_left_outside_corner_cell`

Specifies whether to remove the existed bottom left outside corner cell rule.

`-bottom_right_outside_corner_cell`

Specifies whether to remove the existed bottom right outside corner cell rule.

`-top_left_outside_corner_cell`

Specifies whether to remove the existed top left outside corner cell rule.

`-top_right_outside_corner_cell`

Specifies whether to remove the existed top right outside corner cell rule.

`-bottom_left_inside_corner_cells`

Specifies whether to remove the existed bottom left inside corner cells rule.

`-bottom_right_inside_corner_cells`

Specifies whether to remove the existed bottom right inside corner cells rule.

`-top_left_inside_corner_cells`

Specifies whether to remove the existed top left inside corner cells rule.

Feedback

`-top_right_inside_corner_cells`

Specifies whether to remove the existed top right inside corner cells rule.

`-mirror_left_outside_corner_cell`

Specifies whether to remove the existed mirror left outside corner cell rule.

`-mirror_right_outside_corner_cell`

Specifies whether to remove the existed mirror right outside corner cell rule.

`-mirror_left_inside_corner_cell`

Specifies whether to remove the existed mirror left inside corner cell rule.

`-mirror_right_inside_corner_cell`

Specifies whether to remove the existed mirror right inside corner cell rule.

`-mirror_left_boundary_cell`

Specifies whether to remove the existed mirror left boundary cell rule.

`-mirror_right_boundary_cell`

Specifies whether to remove the existed mirror right boundary cell rule.

`-mirror_left_inside_horizontal_abutment_cell`

Specifies whether to remove the existed mirror left inside horizontal abutment cell rule.

`-mirror_right_inside_horizontal_abutment_cell`

Specifies whether to remove the existed mirror right inside horizontal abutment cell rule.

`-tap_distance`

Specifies whether to remove the existed tap distance rule. If the tap distance rule is to be removed, the top tap cell and bottom tap cell are also removed.

`-top_tap_cell`

Specifies whether to remove the existed top tap cell rule. If the top tap cell rule is to be removed, the bottom tap cell rule is also to be removed or is not existed in current design, then the tap distance rule is also to be removed.

`-bottom_tap_cell`

Specifies whether to remove the existed bottom tap cell rule. If the bottom tap cell rule is to be removed, the top tap cell rule is also to be removed or is not existed in current design, then the tap distance rule is also to be removed.

Feedback

`-prefix`

Specifies whether to remove the existed prefix rule.

`-separator`

Specifies whether to remove the user-specified separator. If yes, the default "!" is used.

`-insert_into_blocks`

Specifies whether to remove the insert into blocks rule.

`-at_va_boundary`

Specifies whether to remove the existed at va boundary rule.

`-no_1x`

Specifies whether to remove the existed no 1x rule. If any of top right outside corner cell rule, bottom right outside corner cell rule, top left outside corner cell rule and bottom left outside corner cell rule is to be removed, then no 1x rule is also to be removed.

`-min_row_width`

Specifies whether to remove the existed min row width rule.

`-min_horizontal_jog`

Specifies whether to remove the existed min horizontal jog rule.

`-min_vertical_jog`

Specifies whether to remove the existed min vertical jog rule.

`-min_horizontal_separation`

Specifies whether to remove the existed min horizontal separation rule.

`-min_vertical_separation`

Specifies whether to remove the existed min vertical separation rule.

`-do_not_swap_top_and_bottom_inside_corner_cell`

Specifies whether to remove the existed do no swap top and bottom inside corner cell rule.

`-allow_protrusive_inside_corner_cell`

Specifies whether to remove the allow protrusive inside corner cell rule.

Feedback

Description

This command is used to remove the existed boundary cell insertion and checking rules. If you specify one option whose corresponding boundary cell rule is not stored in design, then the option is automatically ignored.

Examples

The following example removes all the existed boundary cell rules.

```
prompt> remove_boundary_cell_rules -all
```

---

remove_boundary_optimization

Removes the boundary_optimization restriction on specified pins, cells or modules.

Syntax

int *remove_boundary_optimization*

```
        object_list
```

Data Types

object_list list

Arguments

object_list

Specifies a list of pins, cells or modules where to remove boundary optimization restrictions. Cell or reference names in object_list must be from the current design. If more than one object is specified, they must be enclosed in quotation marks ("") or braces ({}).

Feedback

Description

This command removes the boundary_optimization restriction on objects in object_list, which were previously set using set_boundary_optimization command. The command has no effect on objects specified in the object_list, which were not restrictred earlier. If the pins and cells inherit boundary_optimization restriction from their parent cell and module,pectively this command will not remove boundary_optimization restriction on such pins and cells individually.

Examples

The following example shows how to remove previously set boundary optimization restriction on the cells named U0, U1 and U2.

```
prompt> remove_boundary_optimization { U0 U1 }

prompt> remove_boundary_optimization U2
```

See Also

- compile
- set_boundary_optimization
- report_boundary_optimization

---

remove_bounds

Removes bounds from the current design.

Syntax

int *remove_bounds*

```
[-force]
[-verbose]
[-all]
[bound_list]
```

Data Types

```
bound_list     list
```

Arguments

`-force`

Ignore locked status of the objects. If this option is not provided and any of the affected objects has locked status, command will fail generating tcl error.

Feedback

`-verbose`

Displays verbose deletion information.

`-all`

Removes all bounds from the current design.

`bound_list`

Specifies a list of bounds to remove. The list may contain bound names, patterns, or collections. A collection may be specified by using the *get_bounds* command.

Description

This command removes bound constraints from the current design. The number of removed bounds are returned.

Examples

The following example removes bounds named "movebound1" and "movebound2".

```
prompt> remove_bounds { movebound1 movebound2 }
2
```

The following example removes bounds that match the pattern "movebound*".

```
prompt> remove_bounds movebound*
3
```

The following example removes all bounds in the design.

```
prompt> remove_bounds -all
5
```

See Also

- create_bound
- get_bounds
- add_to_bound
- remove_from_bound

---

remove_buffer

Removes the buffer cells at a specified driver pin or net on a mapped design.

Feedback

Syntax

```
status remove_buffer
-from start_point
-net net_list
cell_list
[-allow_tie_connection]
```

Data Types

start_point	list
net_list	list
cell_list	list
allow_tie_connection	boolean

Arguments

`-from start_point`

Specifies the starting pin or port of the fanout tree from which the buffers or inverter pairs need to be removed. Only driver pins or driver ports can be specified for this option.

This option is mutually exclusive with the *-net* and *cell_list* options.

`-net net_list`

Specifies the starting net of the fanout tree from which the buffers or inverter pairs need to be removed. Only one net can be specified for this option and the driver pin of this net would be considered as the start for fanout traversal. This means that all of the load cells connected to the net are considered in the buffer tree.

This option is mutually exclusive with the *-from* and *cell_list* options.

cell_list

Specifies the buffer or inverter cells to be removed. Each buffer is a cell name or a collection of netlist cells. When inverter cells are specified, they must be specified in pairs.

This option is mutually exclusive with *-from* options.

-allow_tie_connection

Specifies whether the buffers connected with the tie/PG net can be removed.

Description

This command removes buffer cells when you specify a *cell_list* and a buffer or a pair of inverters at the specified pins, or the net on a mapped design. When a driver pin or a net is given, a buffer or a pair of buffers is removed with this driver as the root.

Feedback

This command does not remove buffer/inverter-pair across the logical hierarchy.

This command support transparent interface optimization(TIO) flow, which can remove buffer cells in sub blocks of abstract view from top block.

This command can remove inverters only as pairs. You must specify both of the pairing inverters if you use the *cell_list* argument.

This command accepts the final implementation of buffer or inverters removal, even if it negatively impacts the timing or Design Rule Checking (DRC) violations in the design.

This command support editing a verilog module in the module aspect, through *edit_module*.

This command will check the editability of the block before removing buffer cells.

This command honors design.eco_freeze_silicon_mode. When this app option is true, buffers to remove will be marked as spare cell and renamed by adding _Spare post-fix, instead of being removed from database.

This command is exactly equivalent to *remove_buffers*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes a buffer cell:

```
prompt> remove_buffer -from [get_pins cell1/O]
1

prompt> remove_buffer -net [get_nets net1]
1

prompt> remove_buffer cell2
1
```

Editing a verilog module in the module aspect:

```
prompt> edit_module h1m {remove_buffer {u2 u3 u4 u5 u6}}
```

See Also

- remove_buffers
- all_fanout
- add_buffer

Feedback

- report_cell
- edit_module

---

remove_buffer_trees

Remove all buffer trees or buffer trees between specified drivers / loads

Syntax

status *remove_buffer_trees*

```
[-from pin_or_net_list]
[-source_of pin_list]
[-all]
[-verbose]
```

Data Types

pin_or_net_list	N/A
pin_list	N/A

Arguments

`-from pin_or_net_list`

Specifies a list of driver pins or nets from which buffer trees are to be removed. The command removes all buffers and inverters from these specified pins or nets until encountering the next non-repeaters loads. This option is mutually exclusive with the *-all* option. If this option is specified with *-source_of*, then buffer trees between the *-from* driver pins and *-source_of* load pins are removed.

`-source_of pin_list`

Specifies a list of load pins. The command removes all buffers and inverters between the load pin and the previous non-repeater driver pin, tracing upstream from the load. Only the buffers and inverters directly between that driver and the specified load pins are removed. There might be repeaters in the tree going only to other loads, and they will not be removed. If the cell of a specified pin is a repeater, the cell itself is also removed. This option is mutually exclusive with the *-all* option.

`-all`

Removes all buffer trees in the design. This option is mutually exclusive with the *-from* and *-source_of* option.

Feedback

`-verbose`

Prints detailed info during buffer tree removal, such as buffer instance names whose removal introduce logical feedthroughs in the netlist.

Description

This command removes data path buffer trees in the design.

There are three options for removing buffer trees. It is required to specify one of these options:

- *-all*: Removes all buffer trees
- *-from*: Removes buffer trees from the specified drivers pins or nets
- *-source_of*: Removes the partial buffer trees in the fan-in to the specified load pins

Buffer tree removal is not performed on ideal nets, clock nets, tri-state nets, and multi-driven nets. Some buffers and inverters cannot be removed, including dont_touch cells, size_only cells, and unpaired inverters.

If a buffer removal would introduce a logical feedthrough in the netlist, and the app option *opt.port.eliminate_verilog_assign* is set to *true*, then that buffer will not be removed.

Use *remove_clock_trees* to remove clock trees.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes a buffer tree driven by pin a/O

```
prompt> remove_buffer_trees -from [get_pins a/O]
```

The following example removes the fan-in buffer tree driving pin b/I

```
prompt> remove_buffer_trees -source_of [get_pins b/I]
```

The following example removes all buffer trees

```
prompt> remove_buffer_trees -all
```

See Also

- create_buffer_trees
- remove_clock_trees

Feedback

- report_buffer_trees
- opt.port.eliminate_verilog_assign

---

remove_buffers

Removes the buffer cells at a specified driver pin or net on a mapped design.

Syntax

```
status remove_buffers
-from start_point
-net  net_list
cell_list
[-allow_tie_connection]
```

Data Types

start_point	list
net_list	list
cell_list	list
allow_tie_connection	boolean

Arguments

`-from` *start_point*

Specifies the starting pin or port of the fanout tree from which the buffers or inverter pairs need to be removed. Only driver pins or driver ports can be specified for this option.

This option is mutually exclusive with the *-net* and *cell_list* options.

`-net` *net_list*

Specifies the starting net of the fanout tree from which the buffers or inverter pairs need to be removed. Only one net can be specified for this option and the driver pin of this net would be considered as the start for fanout traversal. This means that all of the load cells connected to the net are considered in the buffer tree.

This option is mutually exclusive with the *-from* and *cell_list* options.

cell_list

Specifies the buffer or inverter cells to be removed. Each buffer is a cell name or a collection of netlist cells. When inverter cells are specified, they must be specified in pairs.

This option is mutually exclusive with *-from* options.

Feedback

-allow_tie_connection

Specifies whether the buffers connected with the tie/PG net can be removed.

Description

This command removes buffer cells when you specify a *cell_list* and a buffer or a pair of inverters at the specified pins, or the net on a mapped design. When a driver pin or a net is given, a buffer or a pair of buffers is removed with this driver as the root.

This command does not remove buffer/inverter-pair across the logical hierarchy.

This command support transparent interface optimization(TIO) flow, which can remove buffer cells in sub blocks of abstract view from top block.

This command can remove inverters only as pairs. You must specify both of the pairing inverters if you use the *cell_list* argument.

This command accepts the final implementation of buffer or inverters removal, even if it negatively impacts the timing or Design Rule Checking (DRC) violations in the design.

This command support editing a verilog module in the module aspect, through *edit_module*.

This command will check the editability of the block before removing buffer cells.

This command honors design.eco_freeze_silicon_mode. When this app option is true, buffers to remove will be marked as spare cell and renamed by adding _Spare post-fix, instead of being removed from database.

This command is exactly equivalent to *remove_buffer*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes a buffer cell:

```
prompt> remove_buffers -from [get_pins cell1/O]
1

prompt> remove_buffers -net [get_nets net1]
1

prompt> remove_buffers cell2
1
```

Editing a verilog module in the module aspect:

```
prompt> edit_module h1m {remove_buffers {u2 u3 u4 u5 u6}}
```

---

remove_bump_clusters

Removes bump clusters from the current design.

Syntax

int *remove_bump_clusters*

```
[-force]
[-verbose]
[-all]
[bump_cluster_list]
```

Data Types

```
bump_cluster_list     list
```

Arguments

`-force`

Ignore locked status of the objects. If this option is not provided and any of the affected objects has locked status, command will fail generating tcl error.

`-verbose`

Displays verbose deletion information.

`-all`

Removes all bump clusters from the current design.

`bump_cluster_list`

Specifies a list of bump clusters to remove. The list may contain bump cluster names, patterns, or collections.

Returns

The number of removed bump clusters.

Feedback

Description

This command removes bump clusters from the current design. Note that objects contained in the bump cluster are all removed from the design.

Examples

The following example removes bump clusters named "bump_cluster1" and "bump_cluster2".

```
prompt> remove_bump_clusters { bump_cluster1 bump_cluster2 }
2
```

The following example removes bump clusters that match the pattern "bump_cluster*".

```
prompt> remove_bump_clusters bump_cluster*
3
```

The following example removes all bump clusters in the design.

```
prompt> remove_bump_clusters -all
5
```

See Also

- create_bump_cluster
- get_bump_cluster_name
- get_bump_cluster_objects

---

remove_bump_region_patterns

Removes the bump region patterns from the current block.

Syntax

int *remove_bump_region_patterns*

```
[-all]
[-verbose]
[bump_region_pattern_list]
```

Data Types

bump_region_pattern_list list

Arguments

-all

Removes all the bump region patterns from the current block.

Feedback

`-verbose`

Displays detailed deletion information.

`bump_region_pattern_list`

Specifies a list of the bump region patterns to remove. The list might contain the bump region pattern names, patterns, or collections. You can specify a collection using the *get_bump_region_patterns* command.

Description

This command removes the bump region patterns from the current block. If a bump region pattern is referenced by one or more bump regions, then it cannot be removed and the tool issues a warning message.

Examples

The following example removes the bump region patterns that match the pattern "brp*".

```
prompt> remove_bump_region_patterns brp*
3
```

The following example removes all bump region patterns in the block.

```
prompt> remove_bump_region_patterns -all
5
```

See Also

- create_bump_region_pattern
- create_bump_region
- get_bump_region_patterns
- get_bump_regions
- get_pseudo_bumps

---

remove_bump_regions

Removes the bump regions from the current block.

Syntax

int *remove_bump_regions*

```
[-all]
[-verbose]
[bump_region_list]
```

Feedback

Data Types

bump_region_list list

Arguments

-all

Removes all bump regions from the current block.

-verbose

Displays detailed deletion information.

bump_region_list

Specifies a list of the bump regions to remove. The list might contain the bump region names, patterns, or collections. You can specify a collection using the *get_bump_regions* command.

Description

This command removes the bump regions from the current block. Removing a bump region invalidates any collections of pseudo bumps owned by the bump region.

Examples

The following example removes the bump regions that match the pattern "region*".

```
prompt> remove_bump_regions region*
3
```

The following example removes all bump_regions in the block.

```
prompt> remove_bump_regions -all
5
```

See Also

- create_bump_region
- create_bump_region_pattern
- get_bump_regions
- get_bump_region_patterns
- get_pseudo_bumps

---

remove_bundle_pin_constraints

Removes all bundle pin constraints from the bundles. If no options are given, all bundle pin constraints in the design are removed.

Feedback

Syntax

int *remove_bundle_pin_constraints*

```
[-bundles bundle_collection]
[-cells cell_collection]
[-self]
```

Data Types

```
bundle_collection  collection
cell_collection    collection
```

Arguments

`-bundles` *bundle_collection*

Specifies the net bundles from which the constraints are removed. If not specified, it applies to all bundles. The bundles must be in the top level of the current design.

`-cells` *cell_collection*

Specifies the block cells from which the constraints are removed. If not specified, and *-self* is also not specified, the command processes all block cells. The cells must be in the top level of the current design.

`-self`

Specifies that the constraints applied to the top-level block are removed. If not specified, and *-cells* is also not specified, it applies to all block cells. It is legal to use *-cells* and *-self* together.

Description

This command removes all existing bundle pin constraints from nets, pins and ports. If you do not specify any arguments, this command removes *all* bundle pin constraints from the design. Note that you can specify both a set of bundles with *-bundles* and a set of block cells with *-cells* (or *-self*). In this case, only constraints which apply to both a specified bundle and a specified cell will be removed.

The *set_editability* command can enable or disable the *remove_bundle_pin_constraints* command for specified blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled with the *set_editability* command.

There are four type of bundle pin constraints, ordered from less specific to more specific:

- Global constraints: Constraint applies to all bundles and all block instances.
- Per-bundle constraints: Constraint applies to a specific bundle and all block instances.

Feedback

- Per-cell constraints: Constraint applies to all bundles and a specific block instance.
- Per-bundle-cell-pair constraints: Constraint applies to a specific bundle and a specific block instance.

In general, this command removes the specified constraint and any other related, more specific constraint. For example, the command *remove_bundle_pin_constraints -bundles B* removes the per-bundle constraint specific to bundle B, but also removes the per-bundle-cell-pair constraints which are specific to bundle B and any cell related to bundle B. Constraints specific to only to a cell but not to bundle B are not removed. In addition, global constraints and are not removed in this example.

This command returns 1 if some constraints could be removed, 0 otherwise.

Examples

The following example removes all bundle pin constraints from the design, including global constraints, per-bundle constraints, per-cell constraints, and per-bundle-cell-pair constraints.

```
prompt> remove_bundle_pin_constraints
```

The following example removes all bundle pin constraints specific to BUNDLE0. Per-bundle and per-bundle-cell-pair constraints which are specific to BUNDLE0 are removed.

```
prompt> remove_bundle_pin_constraints -bundles [get_bundles BUNDLE0]
```

The following example removes all bundle pin constraints specific to cmem0. Per-cell and per-bundle-cell-pair constraints which are specific to cmem0 are removed.

```
prompt> remove_bundle_pin_constraints -cells [get_cells cmem0]
```

The following example removes all bundle pin constraints specific to the top-level block. Per-cell and per-bundle-cell-pair constraints which are specific to the top-level block are removed.

```
prompt> remove_bundle_pin_constraints -self
```

The following example removes all bundle pin constraints specific to the combination of BUNDLE0 and cmem0. Only matching per-bundle-cell-pair constraints are removed.

```
prompt> remove_bundle_pin_constraints -bundles [get_bundles BUNDLE0] \\
   -cells [get_cells cmem0]
`.in -0.25in
```

---

remove_bundles

Remove the specified bundle(s)

Syntax

```
status_value remove_bundles
bundle_list

bundle_list  list
```

Arguments

bundle_list

Specifies a list of bundles to remove.

Description

Removes a list of bundles from the current design.

Examples

The following example removes bundles from the design

```
prompt> remove_bundles [get_bundles BUNDLE_5]
1
prompt> remove_bundles my_bundle
1
```

See Also

- add_to_bundle
- create_bundle
- get_bundles

- report_bundles

Feedback

remove_busplans

Remove entire busplans or specified bits of busplans from design.

Syntax

int *remove_busplans*

```
[-from pins_or_ports]
[buses]
```

Data Types

```
pins_or_ports     collection of pin or port objects
buses             string
```

Arguments

`-from pins_or_ports`

Specify the busplans to be removed based on where the busplan begins. This allows you to remove a subset of the bits of a busplan. This is mutually exclusive with *buses*.

`buses`

Specify the busplans to remove based on the busplan names. The busplans must have been previously created by the *create_busplans* command. This is mutually exclusive with *-from*.

Description

Remove busplans that were previously defined by the *create_busplans* command.

Examples

Create a 8 bit busplan named bus1 and then remove one bit from that busplan.

```
prompt> create_busplans -name bus1 -from B1/OUT1[*] -start_end_cells {B1
 B2 B3 B4}
prompt> report_busplans bus1

****************************************
Report : report_busplans
 ...

****************************************
Start/end at instances: B1 B2 B3 B4

---

remove_cap_cell_rules

Removes the specified cap cell rules.

Syntax

status *remove_cap_cell_rules*

```
[-design design]
[cap_cell_rule_list]
[-all]
```

Data Types

design	string
cap_cell_rule_list	collection

Arguments

`-design design`

Specifies the design in which to remove the cap cell rule(s). If no design is specified, the cap cell rule(s) are removed from the current design.

cap_cell_rule_list

Specifies a list of cap_cell_rules to remove. The list might contain cap cell rules collections specified using the *get_cap_cell_rules* command.

Feedback

This option is mutually exclusive with *-all* option.

`-all`

Removes all cap cell rules from the current design.

This option is mutually exclusive with *cap_cell_rule_list* option.

Description

This command deletes all specified cap cell rules from the current design, unless a different design is specified using the -design option.

Either *cap_cell_rule_list* or *-all* must be specified.

Examples

The following example removes cap cell rules cap_cell_rule_1.

```
prompt> remove_cap_cell_rules [get_cap_cell_rules cap_cell_rule_1]
1
```

See Also

- create_cap_cell_rule

remove_case_analysis

Removes the case analysis value on the specified input.

Syntax

status *remove_case_analysis*

port_or_pin_list

Data Types

port_or_pin_list list

Arguments

port_or_pin_list

Lists ports or pins for which to remove the case analysis entry.

`-all`

Specifies to remove all case analysis in the current design.

Feedback

Description

This command removes previously specified case analysis entries on ports or pins. Case analysis is specified using the *set_case_analysis* command. The command specifies that a pin or port is at a constant logic value (0 or 1), or that only one of the rising or falling transition is valid.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example specifies that ports in0 and in2 are set to the constant logic value 0.

```
prompt> set_case_analysis 0 {in0 in2}
prompt> report_case_analysis

****************************************
Report : case_analysis
 ...

****************************************

Pin name     Case analysis value
--------------------------------
in2          0
in0          0
```

The following example removes the case analysis entry on port in2.

```
prompt> remove_case_analysis {in2}
prompt> report_case_analysis

****************************************
Report : case_analysis
Design : middle
Version:
Date   :
****************************************

Pin name     Case analysis value
--------------------------------
in0          0
```

The following example removes all specified mode that has been set from the current design. prompt> *remove_case_analysis -all*

Feedback

See Also

---

remove_cell

Removes the specified cell instances.

Syntax

integer *remove_cells*

```
[-design design]
[-force]
[cells]
[-all]
```

Data Types

```
design       collection
cells        collection
```

Arguments

`-design design`

Specifies the block from which to remove the cells.

By default, the cells are removed from the current block.

`-force`

Removes the specified cell instances even if their *physical_status* attribute is set to *locked*.

By default, the command raises a Tcl error if the *physical_status* attribute of any of the specified cells has a value of *locked*.

cells

Specifies the cell instances to remove.

This argument and the *-all* option are mutually exclusive; you must specify one.

`-all`

Removes all cell instances from the specified block.

This option and the *cells* argument are mutually exclusive; you must specify one.

Feedback

Description

Removes the specified cell instances from the current block unless otherwise specified by the *-design* option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes all cells whose instance names start with "or2t".

```
prompt> get_cells or2t*
{or2t_1 or2t_2}

prompt> remove_cells or2t*
2
```

See Also

- create_cell
- get_cells

---

remove_cell_array_patterns

Removes cell array patterns.

Syntax

int *remove_cell_array_patterns*

```
[-all]
[-verbose]
[cell_array_pattern_list]
```

Data Types

cell_array_pattern_list list

Arguments

`-all`

Removes all cell_array_patterns from the current block.

`-verbose`

Displays verbose deletion information.

Feedback

cell_array_pattern_list

Specifies a list of cell array patterns to remove. The list may contain cell array pattern names, patterns, or collections. A collection may be specified by using the *get_cell_array_patterns* command.

Returns

The number of removed cell array patterns.

Description

This command removes cell_array_patterns from the current block.

Examples

The following example removes cell_array_patterns that match the pattern "CELL_ARRAY_PATTERN*".

```
prompt> remove_cell_array_patterns CELL_ARRAY_PATTERN*
3
```

The following example removes all cell_array_patterns in the block.

```
prompt> remove_cell_array_patterns -all
5
```

See Also

- get_cell_array_patterns
- create_cell_array_pattern
- report_cell_array_patterns

---

remove_cell_buses

Removes cell buses from the current design.

Syntax

```
collection remove_cell_buses
[-design design]
[-force]
[-block block]
[-cell cell]
-all | -hierarchical | cell_bus_list
```

Feedback

Data Types

```
block           string or collection
cell            string or collection
cell_bus_list   string or collection
```

Arguments

`-design` *design*

Specifies the design in which to remove the cell buses. If no design is specified, the cell buses are removed from the current design.

`-block` *block*

Specifies the block where the cell bus is to be removed. If specified, *remove_cell_buses* has the same effect as *edit_module* in which the module is changed and changes will be on all module occurrences.

`-cell` *cell*

Specifies the cell where the cell bus is to be removed. The cell bus is removed on the cell's reference module. *remove_cell_buses* will first uniquify the reference if needed, then remove the cell bus. When not specified, the cell bus is removed on the current module.

`-force`

Ignores the locked status of cells of the bus cell. If this option is not specified and any of the affected objects has locked status, the command issues a Tcl error and exits.

`-all`

Removes all cell buses of top level only.This option is mutually exclusive to the options *-hierarchical* and *cell_bus_list*.

`-hierarchical`

Removes all the cell buses within the hierarchy relative to current instance.This option is mutually exclusive to the options *-all* and *cell_bus_list*.

cell_bus_list

Specifies a list of cell buses to remove.This option is mutually exclusive to the options *-hierarchical* and *-all*.

Returns

This command returns the removed cell bus count, an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

Feedback

Description

This command removes a list of cell buses from the current design (unless otherwise specified by -design). Individual members of buses remain.

Examples

The following example removes cell bus named *bus1*

```
prompt> remove_cell_buses bus1
1
```

See Also

- create_cell_bus
- get_cell_buses
- report_cell_buses

---

remove_cells

Removes the specified cell instances.

Syntax

integer *remove_cells*

```
[-design design]
[-force]
[cells]
[-all]
```

Data Types

```
design        collection
cells         collection
```

Arguments

`-design design`

Specifies the block from which to remove the cells.

By default, the cells are removed from the current block.

`-force`

Removes the specified cell instances even if their *physical_status* attribute is set to *locked*.

By default, the command raises a Tcl error if the *physical_status* attribute of any of the specified cells has a value of *locked*.

Feedback

cells

Specifies the cell instances to remove.

This argument and the *-all* option are mutually exclusive; you must specify one.

-all

Removes all cell instances from the specified block.

This option and the *cells* argument are mutually exclusive; you must specify one.

Description

Removes the specified cell instances from the current block unless otherwise specified by the *-design* option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes all cells whose instance names start with "or2t".

```
prompt> get_cells or2t*
{or2t_1 or2t_2}

prompt> remove_cells or2t*
2
```

See Also

- create_cell
- get_cells

---

remove_checkpoint_actions

Removes the specified action's definitions, associations, and history from the checkpoint system.

Syntax

```
integer remove_checkpoint_actions
action_names action_names
```

Data Types

action_names list

Feedback

Arguments

`-action_names` *`action_names`*

Specifies the names of the action or flow change for the checkpoint system that will be removed.

Description

This command removes the specified actions from the checkpoint system. Removal includes the action definition created by create_checkpoint_action, the associations to checkpoints defined by associate_checkpoint_action, and any history of that action having run at previous checkpoints reported by get_checkpoint_data.

Examples

The following example removes a checkpoint action or flow change for the checkpoint system.

This example removes the high_congestion_effort action.

```
prompt> remove_checkpoint_actions high_congestion_effort
```

This example removes the power_mode_total and power_mode_leakage actions.

```
prompt> remove_checkpoint_actions "power_mode_total power_mode leakage"
```

- get_checkpoint_data

Feedback

remove_checkpoint_reports

Removes the specified report's definitions, associations, and history from the checkpoint system.

Syntax

```
integer remove_checkpoint_reports
report_names report_names
```

Data Types

```
report_names   list
```

Arguments

```
-report_names report_names
```

Specifies the names of the report for the checkpoint system that will be removed.

Description

This command removes the specified reports from the checkpoint system. Removal includes the report definition created by create_checkpoint_report, the associations to checkpoints defined by associate_checkpoint_report, and any history of that report having run at previous checkpoints reported by get_checkpoint_data.

Examples

This example removes the timing report.

```
prompt> remove_checkpoint_actions timing
```

This example removes the area and power reports.

```
prompt> remove_checkpoint_actions "area power"
```

- reset_checkpoints
- get_checkpoint_data

---

remove_clock

Removes one or more clocks from the current design.

Syntax

string *remove_clocks* -all | *clock_list*

`list clock_list`

Arguments

`-all`

Specifies to remove all clocks in the current design.

`clock_list`

Specifies a list of collections containing clocks or patterns matching the clock names.

Description

Removes the specified clock objects from the current design. You must specify either *clock_list* or *-all*. The command returns the number of clocks removed.

If a removed clock is the only member of a path group, the path group is also removed. For information about path groups, refer to the *group_path* man page. To list all clock sources in the design, use *report_clock*.

All arrival and required times specified by commands *set_input_delay* and *set_output_delay* relatively to the clock that is being removed are also removed.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example removes clock CLK1.

prompt> *remove_clocks CLK1*

The following example removes all clocks from the current design.

prompt> *remove_clocks -all*

Feedback

See Also

- create_clock
- current_design
- get_clocks
- group_path
- report_clock
- set_input_delay
- set_output_delay

---

remove_clock_balance_groups

Remove clock balance groups.

Syntax

```
string remove_clock_balance_groups
 clock_balance_group_list | -all
```

Data Types

```
clock_balance_group_list     collection
```

Arguments

clock_balance_group_list

Specifies a list of clock balance groups to remove. This option and *-all* option are mutually exclusive.

-all

Remove all clock balance groups in the current design. This option and *clock_balance_group_list* are mutually exclusive. Either the *-all* option or *clock_balance_group_list* has to be specified.

Description

This command will remove clock balance groups from constraints.

Examples

The following example removes the specified clock_balance_group.

```
prompt> remove_clock_balance_groups grp1
```

Feedback

See Also

- create_clock_balance_group
- report_clock_balance_groups
- get_clock_balance_groups
- balance_clock_groups

---

remove_clock_balance_points

Removes user-specified constraints set with the *set_clock_balance_points* command.

Syntax

string *remove_clock_balance_points*

```
[-clock clock_list]
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
[-balance_points port_pin_list]
```

Data Types

```
clock_list      list
mode_list       list
corner_list     list
scenario_list   list
port_pin_list   list
```

Arguments

`-clock clock_list`

Specifies the clocks from which to remove the constraints.

By default, the command removes the constraints from all clocks of the current mode.

`-modes mode_list`

Specifies the scenarios from which to remove the balance points. If this option is given, all scenarios of the specified modes are used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

Feedback

`-corners` *corner_list*

Specifies the scenarios from which to remove the balance points. If this option is given, all scenarios of the specified corners and the current mode are used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

`-scenarios` *scenario_list*

Specifies the scenarios from which to remove the balance points. The *-modes* or *-corners* option must not be specified with this option.

`-balance_points` *port_pin_list*

Specifies the ports or pins from which to remove the constraints.

By default, the command removes all constraints from the specified clocks.

Description

This command removes user-specified constraints set with the *set_clock_balance_points* command.

If the command does not find any constraints to remove, it issues an information message.

Examples

The following example removes the constraint set on the gck/CP pin for all clocks in the current mode.

```
prompt> remove_clock_balance_points -balance_points gck/CP
```

See Also

- set_clock_balance_points
- report_clock_balance_points

---

remove_clock_cell_spacings

Removes spacing rules for the specified or all cells in the clock tree.

Syntax

status *remove_clock_cell_spacings*

```
[-clocks clock_list ]
[-lib_cells libcell_name_list ]
```

Feedback

Data Types

```
clock_list          collection
libcell_name_list         list
```

Arguments

`-clocks clock_list`

Specifies the clock trees for which the cell spacing settings will be removed.

`-lib_cells libcell_name_list`

Specifies a list of library cell names, so that only instances on the clock tree of such type would be affected.

Description

This command serves as an instruction to mark relevant existing clock cell spacing rules, previously defined by *set_clock_cell_spacing_rule* command for the removal. In order for the rules to be removed from the relevant instances on the clock network, *synthesize_clock_trees* command needs to be executed. If *-lib_cells* switch is not specified all spacing rules previously defined would be marked for the removal. If it (*-lib_cells* switch) is defined - only spacing rules, that are applied to specified libcells would be marked for the removal. If *-clocks* option is used then it will remove cell spacing settings for specified clock networks.

Examples

The following example marks clock cell spacing rules for the removal for all clock buffers that are of the cell type BUFFD2BWP

```
prompt> remove_clock_cell_spacings -lib_cells mylib/BUFFD2BWP
```

The following example marks all clock cell spacing rules for the removal.

```
prompt> remove_clock_cell_spacings
```

The following example marks clock cell spacing rules, previously defined by *set_clock_cell_spacing -clocks clk* or *set_clock_cell_spacing -clocks clk -lib_cells* * for the removal.

```
prompt> remove_clock_cell_spacings -clocks clk
```

The following example marks clock cell spacing rules, previously defined by *set_clock_cell_spacing -clocks* * *-lib_cells* * for the removal.

```
prompt> remove_clock_cell_spacings -clocks * -lib_cells *
```

Feedback

See Also

- report_clock_cell_spacings
- set_clock_cell_spacing
- cts.placement.cell_spacing_rule_style

---

remove_clock_drivers

Removes cells added with command *create_clock_drivers*.

Syntax

```
status remove_clock_drivers
[-prefix name]
```

Data Types

```
name              string
```

Arguments

`-prefix name`

Only those cells are deleted which have a name starting exactly with the specified prefix. The passed name should not contain a wildcard.

Description

The *remove_clock_drivers* command will delete cells inserted by previous calls of command *create_clock_drivers*. It will remove all repeaters and merge template clones into the originally given template cell. Merging of template clones will only be done if every equivalent input is driven by the same pin as the equivalent original template cell input pin. With the option *-prefix* the set of removed cells can be limited to those which start exactly with the specified prefix.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example removes all cells inserted with calls to *create_clock_drivers* having a name starting with foo.

```
prompt> remove_clock_drivers -prefix foo
```

Feedback

See Also

- create_clock_drivers
- synthesize_multisource_global_clock_trees
- remove_multisource_global_clock_trees

---

remove_clock_exclusivity

Removes clock exclusivity setting on a cell output set by set_clock_exclusivity command.

Syntax

```
Boolean remove_clock_exclusivity
-output output_pins

output_pins list
```

Arguments

`-output`

Specifies the output pin of a cell that has been previously set as exclusive by the set_clock_exclusivity command.

Description

This command removes the exclusivity previously set on an output pin of a cell by the set_clock_exclusivity command. In that case, the tool will no longer infer exclusivity of clocks that pass through the cell and reach that output pin.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example removes two exclusivity points previously set by set_clock_exclusivity command.

```
prompt> remove_clock_exclusivity -output {AND02/Z MUX02/Z}
```

See Also

- set_clock_exclusivity
- report_clock
- set_disable_auto_mux_clock_exclusivity
- time.enable_auto_mux_clock_exclusivity

Feedback

remove_clock_gating_check

Removes clock gating checks for design objects.

Syntax

status *remove_clock_gating_check*

```
[-setup]
[-hold]
[-rise]
[-fall]
[-high | -low]
[object_list]
```

Data Types

object_list list

Arguments

`-setup`

Removes the clock-gating constraint on the setup time only. If you do not specify either the *-setup* or *-hold* option, both setup and hold constraints are removed.

`-hold`

Removes the clock-gating constraint on the hold time only. If you do not specify either the *-setup* or *-hold* option, both setup and hold constraints are removed.

`-rise`

Removes the clock-gating constraint only on the rising delays. If you do not specify either the *-rise* or *-fall* option, constraints on both rising and falling delays are removed.

`-fall`

Removes the clock-gating constraint only on the falling delays. If you do not specify either the *-rise* nor *-fall* option, constraints on both rising and falling delays are removed.

`-high`

Removes the high specification from the object list, previously set by the *set_clock_gating_check* command. You must specify either *-high* or *-low*.

`-low`

Removes the low specification from the object list, previously set up by *set_clock_gating_check* command. This option has to be either high or low.

Feedback

object_list

Specifies a list of objects in the current design for which to remove the clock gating check. The objects can be clocks, ports, pins, or cells. If you specify a cell, all input pins of that cell are affected. If you do not specify any objects, the clock-gating check is removed from the current design.

Description

The *remove_clock_gating_check* command is used to remove any clock-gating check properties applied with the *set_clock_gating_check* command. This command does not remove the clock-gating check itself.

Examples

The following example removes the setup requirement (for rising and falling delays) on all gates in the clock network involved with clock CK1 path.

```
prompt> remove_clock_gating_check -setup [get_clocks CK1]
```

The following example removes the hold requirement on the rising delay of gate and1.

```
prompt> remove_clock_gating_check -hold -rise [get_cells and1]
```

You can also use the *reset_design* command to remove information set by the *set_clock_gating_check* command.

See Also

- current_design
- remove_disable_clock_gating_check
- reset_design
- set_clock_gating_check
- set_disable_clock_gating_check
- time.disable_clock_gating_checks
- time.clock_gating_user_setting_only

---

remove_clock_groups

Removes specific exclusive or asynchronous clock groups from the current design.

Syntax

status *remove_clock_groups*

Feedback

```
-physically_exclusive | -logically_exclusive | -asynchronous | -exclusive
-name name_list | -all
```

Data Types

name_list list

Arguments

`-physically_exclusive`

Removes the groups that are set for physically exclusive clocks. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive. You must choose only one option.

`-logically_exclusive`

Removes the groups that are set for logically exclusive clocks. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive. You must choose only one option.

`-asynchronous`

Removes the group that are set for asynchronous clocks. The *-physically_exclusive*, *-logically_exclusive* and *-asynchronous* options are mutually exclusive. You must choose only one option.

`-exclusive`

Removes the groups that are set for exclusive clocks.

`-name` *name_list*

Removes a list of clock groups which matches the groups in the given names. You should use the *set_clock_groups* command to predefine these names. Substitute the list you want for the *name_list*. The *-name* and *-all* options are mutually exclusive.

`-all`

Removes all groups set for exclusive or asynchronous clocks in the current design. The *-name* and *-all* options are mutually exclusive.

Description

Removes specific exclusive or asynchronous clock groups from the current design. These clock groups are specified by the name_list from the current design. You must specify either *-exclusive* or *-asynchronous* option. You must specify either *name_list* or *-all* option.

To find the names for existing groups, use the *report_clock* command with the *-groups* option.

Feedback

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example removes exclusive clock groups named *mux*.

```
prompt> remove_clock -exclusive -name mux
```

The following example removes all asynchronous clock groups from the current design.

```
prompt> remove_clock -asynchronous -all
```

See Also

- report_clock
- set_clock_groups

---

remove_clock_jitter

Removes clock jitter information previously set by the *set_clock_jitter* command.

Syntax

```
status remove_clock_jitter
   -clock clock_list
   [-modes mode_list]
   [-corners corner_list]
   [-scenarios scenario_list]
```

Data Types

```
clock_list     list
```

Arguments

`-clock clock_list`

Specifies a list of clocks from which to remove the clock jitter.

`-modes mode_list`

Specifies the scenarios to remove the clock jitter. If this option is given, all scenarios of the given modes are used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

Feedback

`-corners` *`corner_list`*

Specifies the scenarios to remove the clock jitter. If this option is given, all scenarios of the given corners and the current mode is used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

`-scenarios` *`scenario_list`*

Specifies the scenarios to remove the clock jitter. The *-modes* or *-corners* option must not be given with this option.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Description

This command removes the cycle-to-cycle jitter or the duty-cycle jitter of the clock that was previously set by the *set_clock_jitter* command.

Examples

The following example removes the cycle-to-cycle jitter of 0.5 and duty-cycle jitter of 0.7 specified on the clock mclk

```
prompt> set_clock_jitter -clock [get_clocks mclk] -cycle 0.5 -duty_cycle
 0.7
prompt> remove_clock_jitter -clock [get_clocks mclk]
```

See Also

- report_clock_jitter
- set_clock_jitter

---

remove_clock_latency

Removes clock latency information from specified objects.

Syntax

string *remove_clock_latency*

```
[-source]
[-offset]
[-clock clock_list]
[-modes mode_list]
[-corners corner_list]
```

Feedback

```
[-scenarios scenario_list]
object_list
```

Data Types

```
clock_list      list
mode_list       list
corner_list     list
scenario_list   list
object_list     list
```

Arguments

`-source`

Specifies that clock source latency should be removed.

`-offset`

Specifies that clock offset latency should be removed.

`-clock clock_list`

Removes from the design any network latency defined on the pin or port objects in *object_list* which refers the clocks in *clock_list*. If the *-clock* option is supplied when *object_list* refers to clock objects, a warning is issued that the option is not relevant in this case and execution of the command proceeds as if *-clock* was not specified. This option does not remove a more general latency setting without any specific clock.

`-modes mode_list`

Specifies the scenarios from which to remove the clock latency. If this option is given, all scenarios of the specified modes will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-corners corner_list`

Specifies the scenarios from which to remove the clock latency. If this option is given, all scenarios of the specified corners and the current mode will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-scenarios scenario_list`

Specifies the scenarios from which to remove the clock latency. The *-modes* or *-corners* option must not be specified with this option.

Feedback

object_list

Provides a list of clocks, ports, or pins.

Description

This command removes clock latency information from the specified objects. It removes the user-specified clock network or source latency information from the specified objects. If a dynamic component of clock source latency has been specified, this will also be removed. If separate latency values for corners exist (specified using *-corners* in the *set_clock_latency* command) then all those corner values are also removed. Clock network latency is the time required for a clock signal on the design to propagate from the clock definition point to a register clock pin. Clock source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design.

Clock latency is managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using the *-modes*, *-corners*, and *-scenarios* options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the *-scenarios* option is specified, the command applies to all of the specified scenarios.

If the *-modes* option is specified, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the *-corners* option is specified, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the *-modes* and *-corners* options are specified, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify *-scenarios* with *-modes* or *-corners*.

Clock network and source latency information is set on objects by using the *set_clock_latency* command. See the *set_clock_latency* man page for more details.

To report clock network and source latency information, use the *report_clocks* command with the *-skew* option.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example removes clock latency information from the clock named *CLK1*.

```
prompt> remove_clock_latency [get_clocks CLK1]
```

Feedback

The following example removes clock source latency information from the clock named *CLK1*.

```
prompt> remove_clock_latency -source \\
[get_clocks CLK1]
```

The following example removes clock source latency information from the clock source port, CLK, with relative clock, *CLK1*. Dynamic component with the source latency is also removed.

```
prompt> remove_clock_latency -source \\
-clock [get_clocks CLK1] [get_ports CLK]
```

remove_clock_routing_rules

Removes routing rules in clock tree synthesis.

Syntax

status *remove_clock_routing_rules*

```
[-clocks clock_list | -nets net_list]
[-net_type sink | internal | root]
[-rule ndr_rule | -default_rule]
```

Data Types

```
clock_list  collection
net_list    collection
ndr_rule    string
```

Arguments

`-clocks clock_list`

Specifies the clock trees of the rules . This option and the *-nets* option are mutually exclusive.

Feedback

`-nets net_list`

Specifies the nets on which the routing rules are removed. This option and the *-clocks* option are mutually exclusive.

`-net_type sink | internal | root`

Specifies the net type of the routing rules. This option cannot work together with the *-nets* option. There are three net types: *sink*, *internal* and *root*.

`-rule ndr_rule`

Specifies the non-default routing rule to be removed.

`-default_rule`

Removes the default routing rule.

Description

This command removes the routing rules used in clock tree synthesis. When none of the options is specified, this command removes all CTS routing rules.

Examples

The following example assigns a non-default rule named *dblespacing* to the sink level nets of clock clk1 in clock tree. Then it removes this rule and reports the routing rules to confirm the settings.

```
prompt> set_clock_routing_rules -clocks clk1 -net_type sink -rule
 dblespacing
1
prompt> report_clock_routing_rules

****************************************
 Report : clock routing rules
 Design : Decoder
 Date   : Thu Nov 29 08:44:45 2012
****************************************
   Clock: clk1 (mode default); Net Type: sink;     Rules: dblespacing

prompt> remove_clock_routing_rules -clocks clk1 -net_type sink
1
prompt> report_clock_routing_rules

****************************************
 Report : clock routing rules
 Design : Decoder
 Date   : Thru Nov 29 08:45:12 2012
****************************************

 No clock routing rule is found.
```

Feedback

See Also

- set_clock_routing_rules
- report_clock_routing_rules

---

remove_clock_sense

The remove_clock_sense command is deprecated. Use the remove_sense command instead.

Multicorner-Multimode Support

This command works only on the current mode.

See Also

- remove_sense
- set_sense

---

remove_clock_skew_groups

Removes the user-defined skew group.

Syntax

remove_clock_skew_groups

```
skew_group_list
```

Data Types

skew_group_list collection

Arguments

skew_group_list

List of skew group names/collections.

Description

This command removes the specified skew group from the design.

Examples

The following example removes the skew group named grp1.

```
prompt> remove_clock_skew_groups [get_clock_skew_groups grp1]
in -0.25i
```

Feedback

See Also

- create_clock_skew_group
- report_clock_skew_groups

---

remove_clock_transition

Removes clock transition time information.

Syntax

string *remove_clock_transition clock_list*

```
clock_list
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]

clock_list     list
mode_list      list
corner_list    list
scenario_list  list
```

Arguments

clock_list

Specifies a list of clocks for which to remove clock transition time.

-modes *mode_list*

Specifies the scenarios that clock transitions will be removed from. If this option is given, all scenarios of the given modes will be used. The *-scenarios* option may not be given with this option. If both *-modes* and *-corners* are given, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

-corners *corner_list*

Specifies the scenarios that clock transitions will be removed from. If this option is given, all scenarios of the given corners and the current mode will be used. The *-scenarios* option may not be given with this option. If both *-modes* and *-corners* are given, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

-scenarios *scenario_list*

Specifies the scenarios that clock transitions will be removed from. The *-modes* or *-corners* option may not be given with this option.

Feedback

Description

Removes clock transition information specified by the *set_clock_transition* command. To list all the set clock transition values, use the *report_clock* command with the *-skew* option.

Clock transition is managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using *-modes*, *-corners*, and *-scenarios* options.

By default, if none of these options are specified, the command is applied to the current scenario. (It will be an error if there is no current scenario). If the *-scenarios* option is given, the command will be applied to all of the specified scenarios. If the *-modes* option is given, the command will be applied to all scenarios of the specified modes. (It will be an error if none of the specified modes have any scenarios.) If the *-corners* option is given, the command will be applied to all scenarios of the specified corners and the current mode. (It will be an error if none of the specified corners have any scenarios with the current mode.) If both the *-modes* and *-corners* options are given, the command will be applied to all scenarios of the specified corners and the specified modes. (It will be an error there are no such scenarios.) It is an error to give *-scenarios* with *-modes* or *-corners*.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example removes clock transition information from all clocks in the current scenario.

```
prompt> remove_clock_transition [all_clocks]
```

See Also

- all_clocks
- create_clock
- report_clocks

---

remove_clock_tree_options

Removes existing target skew or latency constraints.

Feedback

Syntax

status *remove_clock_tree_options*

```
[-clocks clock_list]
[-corners corner_list]
[-skew_groups skew_group_list]
[-all]
[-target_skew]
[-target_latency]
[-copy_exceptions_across_modes]
[-root_ndr_fanout_limit]
[-max_incr_repeater_levels]
```

Data Types

clock_list	list
corner_list	list
skew_group_list	list

Arguments

`-clocks` *clock_list*

Removes target skew or latency on specified clock trees. If not specified, target skew or latency that is previously defined by the *set_clock_tree_options* command without -clocks option is removed.

`-corners` *corner_list*

Removes target skew or latency in specified corners. If it is not specified, target skew or latency set for the current corner is removed.

`-skew_groups` *skew_group_list*

Removes target skew or latency in specified skew groups. If it is not specified, target skew or latency set for the default skew group is removed.

`-all`

Removes all target skew or latency constraints.

`-target_skew`

Specifies that the constraints to be removed are target skew constraints.

`-target_latency`

Specifies that the constraints to be removed are target latency constraints.

`-copy_exceptions_across_modes`

Removes all the *-copy_exceptions_across_modes* settings that are set using the *set_clock_tree_options* command. It can only be used by itself and cannot be combined with other options.

Feedback

`-root_ndr_fanout_limit`

Removes *-root_ndr_fanout_limit* (fanout based nondefault routing rule) settings that are set using the *set_clock_tree_options* command. It can be combined with all other options except the *-copy_exceptions_across_modes* option.

`-max_incr_repeater_levels`

Removes *-max_incr_repeater_levels* settings that are set using the *set_clock_tree_options* command settings are removed.

Description

Removes target skew or latency constraints or fanout based nondefault routing rule settings that are previously defined by the *set_clock_tree_options* command.

Examples

The following example removes the target skew constraint on clock clk1.

```
prompt> remove_clock_tree_options -target_skew -clock clk1
```

The following example removes all target latency constraint on all clocks.

```
prompt> remove_clock_tree_options -target_latency -all
```

See Also

- set_clock_tree_options
- report_clock_tree_options

---

remove_clock_tree_reference_subset

Removes previously defined references from a clock tree.

Syntax

status *remove_clock_tree_reference_subset*

`[-clocks clock_list]`

Data Types

clock_list collection

Arguments

`-clocks clock_list`

Removes references settings for the specified list of clocks.

Feedback

Description

Use this command to remove the specified references settings from clock trees. If the *-clocks* option is used, reference lists of the specified clocks are removed. If the *-clocks* option is not used, all clock tree reference settings will be removed.

Examples

The following example removes reference cell settings for clock tree clk1.

```
prompt> remove_clock_tree_references_subset -clocks clk1
```

See Also

- report_clock_tree_reference_subset
- set_clock_tree_reference_subset

---

remove_clock_trees

Removes buffers and inverters in the clock trees.

Syntax

status *remove_clock_trees*

```
[-clocks clock_list]
[-clock_repeaters_only]
[-keep_ideal_clock_attributes]
[-keep_struct]
```

Data Types

clock_list	collection

Arguments

`-clocks clock_list`

Runs only the clock trees specified in *clock_list*. By default, the command is applied for all currently defined clock trees in all active modes.

`-clock_repeaters_only`

Removes buffers/inverters inserted by clock tree synthesis tools only. This option is off by default.

`-keep_ideal_clock_attributes`

Keeps the ideal clock attributes, such as clock latencies, clock transitions, and clock uncertainties. Those cells with ideal clock attributes will not be removed in this situation.

Feedback

`-keep_struct`

This option will skip reparenting gates, so the clock tree's structure will not change.

Description

This command removes buffers and inverters in clock trees.

Examples

The following example removes all buffers in clock tree named CLK1.

```
prompt> remove_clock_trees -clocks CLK1
```

See Also

- synthesize_clock_trees

---

remove_clock_trunk_endpoints

Removes the status of clock trunk endpoint from pins or ports.

Syntax

status *remove_clock_trunk_endpoints*

```
[-clock clock_list]
[-corners corner_list]
[-auto_clock connected | local | all]
[pins_or_ports]
```

Data Types

```
clock_list     list or collection
corner_list    list or collection
pins_or_ports  collection
```

Arguments

`-clock clock_list`

Removes clock trunk endpoints for the specified clocks. By default, clock trunk endpoints are removed for all clocks.

`-corners corner_list`

Removes corner trunk endpoints for the specified corners. By default, clock trunk endpoints are removed for all corners.

Feedback

pins_or_ports

Removes clock trunk endpoints for the specified pins or ports. By default, clock trunk endpoints are removed for all pins and ports.

`-auto_clock connected | local | all`

Associates clocks at the block level with clocks at the top level. For example, your top-level clock might be called "SYS_CLK", and the same clock in the block might be called "CLK". You can set the association between block clock and top clock by using the *set_block_to_top_map* command, or by using *remove_clock_trunk_endpoints -auto_clock* and specifying the same rule. See the *set_block_to_top_map* man page for more details. Note that the *-clocks* and *-auto_clock* options are mutually exclusive. You can select one of three rules for auto-clock mapping:

- *connected* - The "connected" rule associates block-level clocks with top-level clocks under the following conditions: If a block clock has its source at a block port (a boundary clock), it can be associated to a top-level clock that propagates to that port. If a block clock has its source on an internal pin sources (a local clock), the top-level clock source must be declared at the same pin.
- *local* - The "local" rule maps connected clocks. In addition, if a block clock has its source on an internal pin sources (a local clock) and has no associated top-level clock, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock.
- *all* - The "all" rule maps clocks as in the "local" rule. In addition, if a block clock has its source at a block port (a boundary clock) and no top-level clock propagates to that port, a new top-level clock will be created with the same waveform as the block-level clock. The new top-level clock will be associated with the local block-level clock. The top-level boundary clock will allow timing analysis to be done, but it is not necessarily correct for signoff. You should consider removing or replacing this clock before signoff.

Note that if two block-level clocks are declared at the same boundary port, the "all" rule cannot resolve both of them. This is because it will not automatically declare two conflicting clocks in the top-level block. You must manually declare two top-level clocks, with the appropriate waveforms. After the top clocks exist, *-auto_clock* mapping can associate them with the block clocks.

Description

This command removes clock trunk endpoints during clock trunk planning. Use options to remove clock trunk endpoints only for specified clocks, corners, pins, or ports.

Feedback

Examples

The following example removes all clock trunk endpoints.

```
prompt> remove_clock_trunk_endpoints
1
```

The following example removes clock trunk endpoints for the block1/CLK pin.

```
prompt> remove_clock_trunk_endpoints block1/CLK
1
```

See Also

- gui_load_clock_trunk_planning
- report_clock_trunk_endpoints
- set_clock_trunk_endpoints

---

remove_clock_uncertainty

Removes clock uncertainty information previously set by the *set_clock_uncertainty* command.

Syntax

```
string remove_clock_uncertainty
[object_list |
 -from from_clock
   | -rise_from rise_from_clock
   | -fall_from fall_from_clock
 -to to_clock
   | -rise_to rise_to_clock
   | -fall_to fall_to_clock]
[-rise]
[-fall]
[-setup]
[-hold]
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
[object_list]
```

Data Types

```
object_list         list
from_clock          list
rise_from_clock     list
fall_from_clock     list
to_clock            list
rise_to_clock       list
```

Feedback

```
fall_to_clock       list
mode_list           list
corner_list         list
scenario_list       list
```

Arguments

`-from` *from_clock*

Specifies the source clock for interclock uncertainty. You must specify either the pair of *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to*, or *object_list*; you cannot specify both.

`-rise_from` *rise_from_clock*

Same as the *-from* option, but indicates that *uncertainty* applies only to rising edge of the source clock. You can use only one of the *-from*, *-rise_from*, or *-fall_from* options. Use *-rise_from* instead of the obsolete option *-from_edge rise*.

`-fall_from` *fall_from_clock*

Same as the *-from* option, but indicates that *uncertainty* applies only to the falling edge of the source clock. You can use only one of the *-from*, *-rise_from*, or *-fall_from* options. Use *-fall_from* instead of the obsolete option *-from_edge fall*.

`-to` *to_clock*

Specifies the destination clock for interclock uncertainty. You must specify either the pair of *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to*, or *object_list*; you cannot specify both.

`-rise_to` *rise_to_clock*

Same as the *-to* option, but indicates that *uncertainty* applies only to rising edge of the destination clock. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options. Use *-rise_to* instead of the obsolete option *-to_edge rise*.

`-fall_to` *fall_to_clock*

Same as the *-to* option, but indicates that *uncertainty* applies only to falling edge of the destination clock. You can use only one of the *-to*, *-rise_to*, or *-fall_to* options. Use *-fall_to* instead of the obsolete option *-to_edge fall*.

`-modes` *mode_list*

Specifies the scenarios that uncertainty will be set on. If this option is given, all scenarios of the given modes are used. The *-scenarios* option must not be given with this option. If both *-modes* and *-corners* are given, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

Feedback

`-corners` *`corner_list`*

Specifies the scenarios that uncertainty will be set on. If this option is given, all scenarios of the given corners and the current mode are used. The *-scenarios* option may not be given with this option. If both *-modes* and *-corners* are given, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-scenarios` *`scenario_list`*

Specifies the scenarios that uncertainty will be set on. The *-modes* or *-corners* option must not be given with this option.

`object_list`

Specifies a list of clocks, ports or pins from which uncertainty information is to be removed. You can use either the pair of *-from/-rise_from/-fall_from* and *-to/-rise_to/-fall_to* options or the *object_list* option, but you cannot specify both; they are mutually exclusive.

`-rise`

Specifies that uncertainty is to be removed for only the rising clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use *-rise_to* instead.

`-fall`

Specifies that uncertainty is to be removed for only the falling clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use *-fall_to* instead.

`-setup`

Specifies that only setup check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

`-hold`

Specifies that only hold check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

Description

Removes clock uncertainty information previously set by the *set_clock_uncertainty* command from clocks, ports, pins, or between specified clocks. To display clock uncertainty information, use the *report_clocks* command with the *-skew* option.

Clock uncertainty is managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using *-modes*, *-corners*, and *-scenarios* options.

Feedback

By default, if none of these options are specified, the command is applied to the current scenario, and it is an error if there is no current scenario. If the *-scenarios* option is given, the command is applied to all of the specified scenarios. If the *-modes* option is given, the command is applied to all scenarios of the specified modes, and it is an error if none of the specified modes have any scenarios. If the *-corners* option is given, the command is applied to all scenarios of the specified corners and the current mode, and it is an error if none of the specified corners have any scenarios with the current mode. If both the *-modes* and *-corners* options are given, the command is applied to all scenarios of the specified corners and the specified modes, and it is an error if there are no such scenarios. It is an error to give *-scenarios* with *-modes* or *-corners*.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example removes uncertainty information from a clock named *CLK* and a pin named *clk_buf/Z*.

```
prompt> remove_clock_uncertainty [get_clocks CLK]
prompt> remove_clock_uncertainty [get_pins clk_buf/Z]
```

The following example removes interclock uncertainties between the *PHI1* and *PHI2* clock domains.

```
prompt> remove_clock_uncertainty -from PHI1 -to PHI1
prompt> remove_clock_uncertainty -from PHI2 -to PHI2
prompt> remove_clock_uncertainty -from PHI1 -to PHI2
prompt> remove_clock_uncertainty -from PHI2 -to PHI1
```

---

remove_clocks

Removes one or more clocks from the current design.

Feedback

Syntax

string *remove_clocks* -all | *clock_list*

`list clock_list`

Arguments

`-all`

Specifies to remove all clocks in the current design.

`clock_list`

Specifies a list of collections containing clocks or patterns matching the clock names.

Description

Removes the specified clock objects from the current design. You must specify either *clock_list* or *-all*. The command returns the number of clocks removed.

If a removed clock is the only member of a path group, the path group is also removed. For information about path groups, refer to the *group_path* man page. To list all clock sources in the design, use *report_clock*.

All arrival and required times specified by commands *set_input_delay* and *set_output_delay* relatively to the clock that is being removed are also removed.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example removes clock CLK1.

prompt> *remove_clocks CLK1*

The following example removes all clocks from the current design.

prompt> *remove_clocks -all*

See Also

---

remove_colors

Clears user specified colors from given objects and associated cells.

Syntax

status *remove_colors*

`[object_list]`

Data Types

object_list collection

Arguments

object_list

For cells in the object_list collection, user specified colors of all cells in the collection, and all cells descended from hierarchical cells in the collection will be removed.

For voltage areas in the object_list collection, user specified colors of all voltage areas in the collection, and all cells associated with the voltage areas will be removed.

If omitted, colors are removed from all cells in the current top design.

Description

If *objects* is specified and contains cells, this command removes user specified colors from the cells in the collection and all cells descended from hierarchical cells in the collection. If *objects* is specified and contains designs, this command removes user specified colors from all cells of designs in the collection. If *objects* contains voltage areas, this command removes user specified colors from the voltage areas in the collection and all cells associated with them. If *objects* is omitted or contains no cells, designs or voltage areas, the commands removes user specified colors on all objects in the current design whose color can be set by the set_colors command.

Examples

The following example removes user specified colors from all cells:

```
prompt> remove_colors
```

Feedback

See Also

- set_colors

---

remove_command_hook

Remove hook from command execution

Syntax

string *remove_command_hook* -before *name*

-after *name* -replace *name commandName*

```
string name
string commandName
```

Arguments

`-before name`

Remove the before hook named *name*

`-after name`

Remove the after hook named *name*

`-replace name`

Remove the replace hook named *name*

commandName

Command to update

Description

The *remove_command_hook* removes a hook previously added to a command. When a hook is created via the *add_command_hook* the name of the hook is returned. Use that name to remove the hook. The get_command_hooks command can also be used to determine the name of each registered hook.

Examples

```
prompt> remove_command_hook place_opt -before before0
```

See Also

- add_command_hook
- get_current_hook_command
- get_command_hooks

Feedback

remove_comments

Removes the specified comment.

Syntax

```
collection remove_comments
-all | comments | -design design
```

Data Types

```
comments      collection
design    collection
```

Arguments

`-all`

Removes all comments in the current design.

`-comment`

Specifies a list of comments to remove. The list might contain comment collections, specified using the *get_comments* command.

`-design design`

Specifies the design from which to delete the comment.

Description

This command removes the specified comments from the current block unless otherwise specified by the -design option.

Examples

The following example removes all comments from the current block.

```
prompt > remove_comments -all
{"85"}
```

See Also

- get_comments
- create_comments

remove_constraint_groups

Removes constraint groups from the current design.

Feedback

Syntax

int *remove_constraint_groups*

`-all | constraint_group_list`

Data Types

constraint_group_list string or collection

Arguments

`-all`

Removes all constraint groups in the current design. This is mutually exclusive with *constraint_group_list*.

constraint_group_list

Specifies a list of constraint groups to remove. The list may contain constraint group collections, specified using the *get_constraint_groups* command. This is mutually exclusive with *-all*.

Description

This command removes all specified constraint groups. Constituent objects are disassociated from the removed constraint groups.

The number of removed constraint groups is returned.

Examples

The following example removes constraint groups:

```
prompt> set a [get_constraint_groups shield*]
{"shielding_0", "shielding_1"}

prompt> remove_constraint_groups $a
2
```

The following example removes all constraint groups:

```
prompt> remove_constraint_groups -all
10
```

See Also

- create_wire_matching
- create_length_limit
- create_differential_group
- create_net_shielding

Feedback

- create_net_priority
- create_bus_routing_style
- get_constraint_groups

---

remove_corners

Removes one or more corners in multi corner analysis.

Syntax

status *remove_corners*

```
-all | corner_list
```

Data Types

```
corner_list     collection
```

Arguments

`-all`

Removes all corners from memory.

corner_list

Specifies a list of unique corner strings to remove from memory.

Description

This command removes the specified corners from memory. To list the corners in the design, use the *all_corners* command.

The command returns the number of corners that were removed.

Examples

The following example removes the two corners named corner1 and corner2.

```
prompt> remove_corners {corner1 corner2}
1
```

See Also

- all_corners
- create_corner
- current_corner

Feedback

- get_corners
- set_scenario_status

---

remove_ctp_constraints

Removes the existing CTP constraints.

Syntax

string *remove_ctp_constraints*

```
[-cells cell_collection]
```

Data Types

```
cell_collection       collection
```

Arguments

`-cells cell_collection`

Specifies the blocks from which to remove CTP constraints. If you specify this option, the command only removes the CTP constraints for the specified blocks.

Description

This command removes CTP constraints from blocks. If you do not specify any arguments, this command removes CTP constraints for all blocks.

The *set_editability* command can enable or disable the *remove_ctp_constraints* command for specified blocks. This command has no effect on the blocks that are disabled with the *set_editability* command.

Examples

The following example removes the CTP constraints for all blocks in the design.

```
prompt> remove_ctp_constraints
```

See Also

- synthesize_clock_trunks
- set_ctp_constraints
- report_ctp_constraints
- set_editability

Feedback

remove_custom_shields

Removes shielding for the specified nets if the shielding was created with Custom Router previously.

Syntax

status *remove_custom_shields*

```
[-nets nets]
[-keep_session (false|true)]
```

Data Types

nets a collection of nets to process

Arguments

`-nets` *nets*

Specifies the collection of nets for which shielding witll be deleted. If not specified, all top level nets in the design will be processed. Nets without shielding shapes created by the custom router will be skipped.

`-keep_session` *bool*

Specifies whether or not the custom router view of the data will be retained after the command completes. Use true only if you expect to perform additional custom route commands immediately after the current command. The default is false.

Description

The *remove_custom_shields* command removes shielding created by the custom router for a set of specified nets.

remove_cut_metals

This command removes cut metals at metal cut ends, where the cut metals are generated by *create_cut_metals* command.

Syntax

status *remove_cut_metals*

Description

This command deletes cut metal shapes of top-design, where the cut metals shapes are created by *create_cut_metals* command.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

```
prompt> remove_cut_metals
```

See Also

- remove_cut_metals

---

remove_data_check

Removes specified data-to-data checks previously set by the *set_data_check* command.

Syntax

string *remove_data_check*

```
-modes mode_list
-corners corner_list
-scenarios scenario_list
-from from_object
   | -rise_from from_object
   | -fall_from from_object
-to to_object
   | -rise_to to_object
   | -fall_to to_object
[-setup | -hold]
[-clock clock]
[-all]
```

Data Types

```
from_object     collection
to_object       collection
clock_object    collection
```

Arguments

`-modes mode_list`

Removes data check for scenarios of these modes (default is current mode, or current scenario if neither mode nor corner is specified)

`-corners corner_list`

Removes data check for scenarios of these corners (default is current scenario if neither mode nor corner is specified)

Feedback

`-scenarios` *scenario_list*

Removes data check for these scenarios (default is current scenario)

`-from` *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. Both rising and falling checks are removed. You must specify one of *-from*, *-rise_from*, or *-fall_from*.

`-to` *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. Both rising and falling checks are removed. You must specify one of *-to*, *-rise_to*, or *-fall_to*.

`-rise_from` *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. This is similar to the *-from* option, but applies to only rising delays at the related pin. You must specify one of *-from*, *-rise_from*, or *-fall_from*.

`-fall_from` *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. This is similar to the *-from* option, but applies to only falling delays at the related pin. You must specify one of *-from*, *-rise_from*, or *-fall_from*.

`-rise_to` *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. This is similar to the *-to* option, but applies to only rising delays at the constrained pin. You must specify one of *-to*, *-rise_to*, or *-fall_to*.

`-fall_to` *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. This is similar to the *-to* option, but applies to only falling delays at the constrained pin. You must specify one of *-to*, *-rise_to*, or *-fall_to*.

`-setup`

Indicates that only the setup data check is to be removed. If neither *-setup* nor *-hold* is specified, both setup and hold checks are removed.

`-hold`

Indicates that only the hold data check is to be removed. If neither *-setup* nor *-hold* is specified, both setup and hold checks are removed.

Feedback

`-clock` *clock_object*

Indicates that the data check for the specified clock at the related pin is to be removed. This option applies only if a previous *set_data_check* command used the *-clock* option to specify the same clock; otherwise, this option is ignored.

`-all`

Indicates that all the data checks to be removed. The command ignores all other options and removes all data checks.

Description

The *remove_data_check* command specifies data-to-data check(s) to be removed between the *from* object and the *to* object for the specified options. These checks were previously set using the *set_data_check* command.

Multicorner-Multimode Support

This command applies to the current scenario only.

Examples

The following example removes a data-to-data check from and1/B to and1/A with respect to the rising edge of signals at and1/B. Both setup and hold checks are removed.

```
prompt> remove_data_check -rise_from and1/B -to and1/A
```

The following example removes setup data-to-data checks between and1/B and and1/A with respect to the rising edge of signals at and1/B and the falling edge of signals at and1/A, coming from startpoints triggered by the CK1 clock:

```
prompt> remove_data_check -rise_from and1/B \\
   -fall_to and1/A -setup -clock [get_clock CK1]
```

See Also

- set_data_check
- update_timing

---

remove_density_rules

Removes density rules from the specified technology data.

Syntax

status *remove_density_rules*

Feedback

```
[-tech tech]
[-library library]
[-all]
[density_rules]
```

Data Types

```
tech          collection
library       collection
density_rules collection
```

Arguments

`-tech tech`

Specifies the technology data from which to remove the density rules.

If you do not specify the *-tech* or *-library* option, the command removes the rules from the technology data of the current library.

`-library library`

Specifies the library from which to remove the density rules.

If you do not specify the *-tech* or *-library* option, the command removes the rules from the technology data of the current library.

`-all`

Removes all density rules from the specified technology data.

The *-all* option and *density_rules* argument are mutually exclusive; you must specify one of these arguments.

density_rules

Specifies the density rules to remove. You can specify any combination of rule names, patterns, or collections, which are created by the *get_density_rules* command.

The *-all* option and *density_rules* argument are mutually exclusive; you must specify one of these arguments.

Description

The *remove_density_rules* command removes the specified density rules from the specified technology data.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

You can use either of the commands in the following example to remove all density rules from the technology data in the current library.

```
prompt> remove_density_rules -all

prompt> remove_density_rules [get_density_rules *]
```

The following example removes the density rules associated with the M3 layer from the technology data in the current library.

```
prompt> remove_density_rules \\
   [get_density_rules -filter "layer_name==M3"]
1
```

See Also

- create_density_rule
- get_density_rules

---

remove_design_rules

Removes design rules (design_rule) from the current technology object.

Syntax

```
integer remove_design_rules
[-all]
[design_rule_list]
```

Data Types

design_rule_list collection

Arguments

-all

Removes all design rules.

The *-all* option and *design_rule_list* argument are mutually exclusive; you must specify one.

design_rule_list

Specifies the design rules to remove. You can specify the rules by name or as a collection.

The *-all* option and *design_rule_list* argument are mutually exclusive; you must specify one.

Feedback

Description

This command removes design rules from the current technology object.

This command returns the number of rules removed. If there is a command syntax error, it raises a TCL_ERROR.

Examples

The following example removes the design rule named DESIGN_RULE_0.

```
prompt> remove_design_rules DESIGN_RULE_0
1
```

See Also

- create_design_rule
- get_design_rules
- report_design_rules

---

remove_dff_connection_files

Removes specified data flow flyline connections file.

Syntax

```
status remove_dff_connection_files
[-filename file_name]
[-quiet]
```

Data Types

```
file_name          string
```

Arguments

`-filename file_name`

Specifies the data flow flylines connection file that should be removed.

`-quiet`

Specifies that the command should run in quiet mode and skip issuing messages as much as possible.

Description

This command removes a specified data flow flylines connection file. The data flow flylines connection file must have been created by the *write_dff_connections* command.

Feedback

Examples

The following example removes a DFF connections file named f1.

```
prompt> remove_dff_connection_files -filename f1
```

See Also

- write_dff_connections
- read_dff_connections
- remove_dff_connection_files

---

remove_dff_trace_filters

Removes filter patterns from the list of filters used by the *compute_dff_connections* command

Syntax

```
compute_dff_connections
[-blocks list_of_blocks]
-type pin | net
-patterns list_of_patterns | -all
```

Data Types

```
list_of_blocks    list
list_of_patterns  list
```

Arguments

`-blocks list of blocks`

Specifies a list of block names from which to remove the specified filter patterns. If not specified, the patterns are removed from the special "all blocks" list.

`-type pin | net`

Specifies the type of filter to remove, either *pin* or *net*.

`-patterns list_of_patterns`

Specifies a list of patterns to remove from the specified filter type list. Patterns must match existing patterns exactly (no wildcard support during removal).

`-all`

Removes all patterns from the specifies blocks, or if *-blocks* is not specified, from all block lists including the special "all blocks" list.

Feedback

Description

This command removes trace filter patterns used by the Data Flow Flylines (DFF) tracer. See the *compute_dff_connections* command for more information.

A GUI interface to manage filter patterns is available as part of the Data Flow Flylines tool in the GUI. You can access the interface with the Reload option.

GENERAL USAGE

This command removes one or more patterns from a list of existing patterns used by the *compute_dff_connections* command when tracing through the netlist.

Examples

The following example removes a pattern "M1/*" from the trace filter list previously added for block B1.

```
prompt> remove_dff_trace_filters -type pin -blocks B1 -patterns "M1/*"
1
```

See Also

- compute_dff_connections
- create_dff_trace_filters
- write_dff_trace_filters

---

remove_dft_location

Removes DFT hierarchy location specifications for the current design.

Syntax

status *remove_dft_location*

```
[-type logic_type]
```

Data Types

```
logic_type      string
```

Arguments

`-type logic_type`

Specifies the types of DFT hierarchy location specifications to be removed from the current design. The following values are valid for *logic_type*:

CODEC

Feedback

```
WRAPPER
PLL
SERIAL_CNTRL
```

You can specify a list of multiple types with this option.

To remove a default DFT hierarchy location specification that was applied using the *set_dft_location* command without the *-include* option, do not specify a value for this option.

Description

The *remove_dft_location* command removes DFT hierarchy location specifications for the current design.

Examples

The following example removes the DFT hierarchy location for the design named *top*:

```
prompt> current_design top

prompt> set_dft_location -include {CODEC} core_inst/CODEC

prompt> remove_dft_location -type {CODEC}
Removed DFT location 'core_inst/CODEC' for type 'CODEC' for design 'top'.
1
```

See Also

- report_dft
- set_dft_location

---

remove_dft_partition

Removes list of design DFT partition created during DFT synthe- sis. Command not supported after DFT is inserted.

Syntax

status *remove_dft_partition <list of DFT partitions>* status *remove_dft_partition* Removes current dft partition

```
[-partition_names partition_name]
```

Data Types

```
partition_name          list of strings
```

Feedback

Arguments

`partition_name`

Specifies a user-defined text string containing only alphanumeric characters (a-z, A-Z, 0-9) and the underscore (_). The name default_partition is not allowed as the partition name. To list all the defined partitions, you can use the *report_dft_partitions* command. Specifies name of partition that has to be deleted. if not defined command will delete current dft partition.

Description

The *remove_dft_partition* command allows you to remove one or more DFT partitions which were defined as part of the DFT flow setup. The partition is referenced to the top level in a top-down flow.

The command accepts a list of previously defined partition names. To list all the defined partitions, you can use the report_dft_par- titions command. If no DFT partition name is supplied, the command will delete current dft partition. default_partition is not allowed as a valid input for the command.

Along with the partition we also delete all configurations defined in this partition i.e. scan, wrapper, compression etc. We also delete the signals defined in that partition and make sure all data defined for that partition is erased.

Examples

The following example defines two design partitions for use in a DFT insertion and deletes one of them. The design contains at the top level 4 hierarchical cells named U1, U2, U3 and U4, respectively.

prompt> define_dft_partition part_1\ -include {U1 U2}

prompt> define_dft_partition part_2\ -include {U3 U4}

prompt> remove_dft_partition {part_1}

The following example defines two design partitions for use in a DFT insertion based on their clocks named clk_st1 and clk_st2, respectively and subsequently deletes them.

prompt> define_dft_partition part_1\ -clocks {clk_st1}

prompt> define_dft_partition part_2\ -clocks {clk_st2}

prompt> remove_dft_partition -partition_names {part_1 part_2}

Feedback

See Also

- current_dft_partition
- define_dft_partition
- report_dft

---

remove_dft_signal

Removes attributes from specified ports that identify those ports as DFT signals in the current design.

Syntax

status *remove_dft_signal*

```
[-port port_list]
[-test_mode mode_name_list]
[-hookup_pin pin_name]
```

Data Types

```
port_list       list
mode_name_list  list
pin_name        string
```

Arguments

`-port port_list`

Specifies a list of ports to which the command applies.

`-test_mode mode_name_list`

Specifies the modes to which the command applies. The default mode is *Internal_scan*. Specifying *all* as the *mode_name_list* indicates that the specification applies to all modes. Any mode other than the default mode or *all* must be created before running the command with this option.

`-hookup_pin pin_name`

Specifies the hookup pin to which the command applies.

Description

The *remove_dft_signal* command removes the attributes from specified ports that identify those ports as DFT signal ports in the current design. These attributes were placed on the ports with the *set_dft_signal* command.

Feedback

Examples

The following example removes the DFT signal attributes from the *TM* port:

```
prompt> remove_dft_signal -port TM
```

See Also

- compile
- insert_dft
- preview_dft
- report_dft_signal
- report_dft
- set_dft_signal

---

remove_disable_clock_gating_check

Restores clock gating checks previously disabled by the *set_disable_clock_gating_check* command.

Syntax

string *remove_disable_clock_gating_check*

```
        object_list
```

Data Types

object_list list

Arguments

object_list

Specifies a list of cells and pins for which the clock gating check is restored.

Description

The *remove_disable_clock_gating_check* command restores clock gating checks previously disabled by the *set_disable_clock_gating_check* command. These two commands only affect automatically inferred clock gating checks, not library-defined checks.

Specify the list of cells and pins for which to restore the clock gating checks. The command restores clock gating checks for those objects.

Feedback

The command does not tell you whether any clock gating checks are being performed on the specified objects or whether any such checks were previously disabled. To get this type of information, use the *report_clock_gating_check* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following command restores clock gating checks on cell U123 previously disabled by the *set_disable_clock_gating_check* command.

```
prompt> remove_disable_clock_gating_check [get_cells U123]
```

The following command restores clock gating checks that use pin U123/I as a gating enable pin or gating clock pin, previously disabled by the *set_disable_clock_gating_check* command.

```
prompt> remove_disable_clock_gating_check [get_pins U123/I]
```

See Also

- report_clock_gating_check
- set_disable_clock_gating_check

---

remove_disable_timing

Enables the previously disabled timing arcs.

Syntax

string *remove_disable_timing*

```
[-from from_pin_name]
[-to to_pin_name]
[-loop_break]
object_list

string from_pin_name
string to_pin_name
list object_list
```

Arguments

`-from from_pin_name`

Feedback

`-to` *to_pin_name*

Specifies that only the arcs between these two pins on the specified cell or library cell be disabled.

-loop_break

Indicate whether constraints coming from tool, not user.

object_list

Specifies a list of cells, pins, library cells, library cell pins, or ports. The *object_list* must contain only cells or library cells (if *-from* and *-to* are specified).

Description

Restore timing arcs previously disabled with the *set_disable_timing* command. When *-from* and *-to* pins are specified, all arcs between these two pins on the cell or library cell are restored.

To list the timing arcs for a library cell, use *report_lib -timing_arcs*.

Examples

The following example restores disabled setup and hold arcs between pins CLK and TE on library cell SFF1.

prompt> *remove_disable_timing -from CLK -to TE tech_lib/SFF1*

The following example restores all disabled cell arcs from or to pin A on cell U1/U2.

prompt> *remove_disable_timing U1/U2/A*

See Also

- report_lib
- set_disable_timing

---

remove_drc_error_data

Removes DRC error data objects.

Syntax

```
status remove_drc_error_data
drc_error_data
[-force]
```

Data Types

drc_error_data collection

Feedback

Arguments

drc_error_data

Specifies the collection of DRC error data objects to remove.

-force

Removes the specified DRC error data object, regardless of pending multiple opens that have not been matched with a close.

Description

The *remove_drc_error_data* command removes the specified DRC error data objects. The command first closes the error data objects, which decrements the open count for the error data objects. If the open count decrements to zero, the command removes the error data object from memory. If the error data object was created as an external error data file, the error data file is removed from disk.

The open count for a DRC error data object is incremented each time you run the *create_drc_error_data* or *open_drc_error_data* command on it. The open count is decremented each time you run the *close_drc_error_data* command. The error data object is removed from memory when the open count reaches zero.

Use the *-force* option to remove the error data object from memory and remove the external error data file from disk, regardless of the open count value.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes the DRC error data object named "dppinassgn.err".

```
prompt> remove_drc_error_data dppinassgn.err
1
```

The following example first opens an error data object named "dppinassgn.err", and then deletes it.

```
prompt> set data [open_drc_error_data dppinassgn.err]
{"dppinassgn.err"}
prompt> remove_drc_error_data $data
1
```

See Also

- save_drc_error_data

---

remove_drc_error_types

Removes physical DRC error type objects.

Syntax

```
status remove_drc_error_types
-error_data drc_error_data
drc_error_types
```

Data Types

```
drc_error_data      collection
drc_error_types     collection
```

Arguments

`-error_data` *drc_error_data*

Specifies the error data from which to remove physical DRC error types.

drc_error_types

A collection of physical DRC error type objects to remove.

Description

The *remove_drc_error_types* command removes physical DRC error type objects from the given error data. When an error type is removed, all errors of the type are also deleted from the error data.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all error_types that have the error_class value of *short*.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_error_types -error_data $data \\
   [get_drc_error_types -error_data $data -filter {error_class==short}]
```

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes the error type named "pin short".

Feedback

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_error_types -error_data $data \\
   [get_drc_error_types -error_data $data {"pin short"}]
```

See Also

---

remove_drc_error_waivers

Remove DRC error waiver objects

Syntax

```
status remove_drc_error_waivers
-all
drc_error_waiver
```

Data Types

drc_error_waiver string or collection

Arguments

`-all`

Remove all the user-defined waiver objects. You must specify either *-all* or *drc_error_waiver*.

drc_error_waiver

Specifies the collection of DRC error waiver objects to remove. You must specify either *-all* or *drc_error_waiver*.

Description

The *remove_drc_error_waivers* command removes DRC error waiver objects.

You must specify either *-all* or *drc_error_waiver*.

Feedback

Examples

The following example removes all the waivers.

```
prompt> remove_drc_error_waivers -all
```

The following example removes the error waiver named "w1".

```
prompt> remove_drc_error_waivers w1
```

See Also

- create_drc_error_waiver
- remove_waiver_containers
- get_drc_error_waivers

---

remove_drc_errors

Removes physical DRC error data objects.

Syntax

```
status remove_drc_errors
-error_data drc_error_data
drc_errors
```

Data Types

```
drc_error_data      collection
drc_errors          collection
```

Arguments

`-error_data drc_error_data`

Specifies the error data from which to remove errors.

drc_errors

A collection of physical DRC error data objects to remove.

Description

The *remove_drc_errors* command removes physical DRC error objects from the given error data.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all errors that have the status value of *fixed*.

Feedback

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> remove_drc_errors -error_data $data \\
        [get_drc_errors -error_data $data -filter {status==fixed}]
```

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then removes all errors that are of type "pin short".

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> set pinShortType [get_drc_error_types -error_data $data {"pin
 short"}]
{"pin short"}
prompt> remove_drc_errors -error_data $data \\
        [get_drc_errors -error_data $data -of_objects $pinShortType]
```

See Also

- create_drc_error
- open_drc_error_data
- remove_drc_error_data
- remove_drc_error_types

---

remove_drive_resistance

Removes drive resistance for input or inout ports.

Syntax

string *remove_drive_resistance*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
port_list
```

Data Types

```
mode_list      list
corner_list    list
scenario_list  list
port_list      list
```

Feedback

Arguments

`-modes` *`mode_list`*

Specifies the scenarios from which to remove the drive resistance. If this option is given, all scenarios of the specified modes will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-corners` *`corner_list`*

Specifies the scenarios from which to remove the drive resistance. If this option is given, all scenarios of the specified corners and the current mode will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-scenarios` *`scenario_list`*

Specifies the scenarios from which to remove the drive resistance. The *-modes* or *-corners* option must not be specified with this option.

`port_list`

Specifies a list of input or inout port names in the current design from which to remove the drive values.

Description

The *remove_drive_resistance* command removes the drive resistance value from one or more input or inout ports. This is equivalent to using *set_drive 0*. In fact, that is how this command works. If output ports are passed into *remove_drive_resistance*, a DES-003 message is issued, indicating that *set_drive* could not be performed on those ports.

Port drive resistance is managed on a per-scenario basis. For designs with multiple scenarios, you can specify different drive resistance for different scenarios by using *-modes*, *-corners*, and *-scenarios* options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the *-scenarios* option is given, the command applies to all of the specified scenarios.

If the *-modes* option is given, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

If the *-corners* option is given, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the *-modes* and *-corners* options are given, the command applies to all scenarios of the specified corners and the specified

Feedback

modes. The tool issues an error if there are no such scenarios. It is an error to specify *-scenarios* with *-modes* or *-corners*.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example sets a drive resistance of 5 on ports A, B, and C, reports the new drive resistance, removes the drive resistance on port A, and reports the resistance after removal. In the final report, only drive resistance for ports B and C is reported.

```
prompt> set_drive_resistance 5 [get_ports {A B C}]
1

prompt> report_ports -drive {A B C}

remove_driving_cell

Removes port driving cell information.

Syntax

string *remove_driving_cell*

```
[-rise]
[-fall]
[-min]
[-max]
[-clock clock_name]
[-clock_fall]
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
port_list
```

Data Types

clock_name	string
mode_list	list
corner_list	list
scenario_list	list
port_list	list

Arguments

`-rise`

Removes driving cell information only for the rising port transition.

`-fall`

Removes driving cell information only for the falling port transition.

`-min`

Removes driving cell information only for minimum timing analysis.

`-max`

Removes driving cell information only for maximum timing analysis.

Feedback

`-clock clock_name`

Removes the driving cell set relative to the specified clock.

`-clock_fall`

Removes the driving cell relative to the falling edge of the clock. The default is the rising edge.

`-modes mode_list`

Specifies the scenarios from which to remove the driving cells. If this option is given, all scenarios of the specified modes will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-corners corner_list`

Specifies the scenarios from which to remove the driving cells. If this option is given, all scenarios of the specified corners and the current mode will be used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* will be used.

`-scenarios scenario_list`

Specifies the scenarios from which to remove the driving cells. The *-modes* or *-corners* option must not be specified with this option.

port_list

Provides a list of input or output ports.

Description

Removes driving cell information from the specified ports. The driving cell information is specified with the *set_driving_cell* command. The default is to remove all *-rise* and *-fall* information.

To see port drive information, use the *report_ports -drive* command.

Driving cells are managed on a per-scenario basis. For designs with multiple scenarios, you can specify scenarios by using *-modes*, *-corners*, and *-scenarios* options.

By default, if none of these options are specified, the command applies to the current scenario. The tool issues an error if there is no current scenario. If the *-scenarios* option is given, the command applies to all of the specified scenarios.

If the *-modes* option is given, the command applies to all scenarios of the specified modes. The tool issues an error if none of the specified modes have any scenarios.

Feedback

If the *-corners* option is given, the command applies to all scenarios of the specified corners and the current mode. The tool issues an error if none of the specified corners have any scenarios with the current mode. If both the *-modes* and *-corners* options are given, the command applies to all scenarios of the specified corners and the specified modes. The tool issues an error if there are no such scenarios. It is an error to specify *-scenarios* with *-modes* or *-corners*.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

The following example removes all driving cell information for port IN2.

```
prompt> remove_driving_cell IN2
```

See Also

- report_ports
- set_driving_cell

---

remove_duplicate_timing_contexts

Removes duplicate Scenarios, Modes and Corners for the current block

Syntax

int *remove_duplicate_timing_contexts*

```
[-analyze_only]
[-exclude_group_path_directives]
```

Arguments

`-analyze_only`

Only perform minimization analysis.

`-exclude_group_path_directives`

Disregard the group_path directive, which may allow further mode minimization.

Description

This command removes duplicate Scenarios, Modes and Corners. Scenarios that are determined to be duplicates and have the same Scenario status values are removed. Scenarios of Modes that are determined to be duplicate are re-assigned to a common Mode. Corners may be added to achieve that reassignment. Additional Corners will be

Feedback

named consistently to the Corner they were created from, with an _d suffix, where d is an integer. Scenarios of Corners that are determined to be duplicate are reassigned to a common Corner.

If the reduction of Modes, Corners or Scenarios is possible, it is expected that both runtime and capacity will be improved.

Switching activity is not considered when determining duplicate Modes. It may therefore be necessary to re-annotate switching activity manually where mode reduction was achieved.

If the design makes use of the *set_block_to_top_map* command to map Block to top corners, this mapping will need to be manually updated when a mapped top corner is removed. The *report_block_to_top_map* command may be used to determine the current mapping.

This command writes temporary files into the directory specified by the *shell.common.tmp_dir_path* application option. If the command reports an error in creating files, check the value of the application option and ensure that the directory is writable.

After scenarios is reduced, the left scenario's SI related flag will also be updated with the global SI app option(time.si_enable_analysis). For example, when time.si_enable_analysis is false, even if the scenario SI analysis flag was true before removing, it will be set to false after scenario is reduced.

Multicorner-Multimode Support

This command uses information from all scenarios

Examples

The following example uses the *remove_duplicate_timing_contexts* command to analyze the timing contexts of the design and implement all possible mode, corner and scenario reductions. Any reduction is expected to reduce the design's memory footprint and runtime through the subsequent design flow. In order to reduce the current memory footprint it is necessary to save the design, quit the tool session and restart the tool session.

```
prompt> save_block -as des/pre-reduction;
prompt> report_qor -summary -include {setup hold};
prompt> remove_duplicate_timing_contexts;
Minimization Summary:
Modes    : Reduced from 4 to 2
Corners  : No reduction was possible
Scenarios: Reduced from 10 to 8
1
prompt> report_qor -summary -include {setup hold};
prompt> save_block -as des/post-reduction;
prompt> exit;
1
```

---

remove_early_data_check_records

Removes the early data check records.

Syntax

collection *remove_early_data_check_records*

```
[-hierarchical]
[records]
```

Arguments

`-hierarchical`

Traverses the hierarchy and removes records for each design. This is optional.

`records`

Displays the list of records to remove.

Description

This command removes the check records from the current design. When you specify the -hierarchy option, it traverses the hierarchy and removes records for each design.

Examples

The following example shows how to remove records:

```
prompt> get_early_data_check_records
{place.port_type_mismatch@clk place.port_type_mismatch@repairedport1
route.missing_layer_direction@feed_in}
```

Feedback

```
prompt> get_early_data_check_records -hierarchical
{place.port_type_mismatch@clk place.port_type_mismatch@repairedport1
route.missing_layer_direction@feed_in route.layer_name_mismatch@out}

The following command removes a specified record:
prompt> remove_early_data_check_records place.port_type_mismatch@clk
1

The following command removes all the repaired records
prompt> remove_early_data_check_records [get_early_data_check_records
-filter "policy==repair"]
Records removed successfully !!

prompt> get_early_data_check_records
{route.missing_layer_direction@feed_in}

The following command removes all the records from the current design
prompt> remove_early_data_check_records
1

prompt> get_early_data_check_records
prompt>

prompt> get_early_data_check_records -hierarchical
{route.layer_name_mismatch@out}

The following command removes all the records from the current and
 reference design
prompt> remove_early_data_check_records -hierarchical
1

prompt> get_early_data_check_records -hierarchical
prompt>
```

See Also

- set_early_data_check_policy
- get_early_data_check_records

---

remove_eco_bus_buffer_patterns

Removes the specified ECO bus buffer pattern.

Syntax

```
status remove_eco_bus_buffer_patterns
[patterns | -all]
[-verbose]
```

Feedback

Data Types

patterns collection

Arguments

patterns

Specifies the list of ECO bus buffer patterns to remove.

-all

Removes all ECO bus buffer patterns.

-verbose

Reports the names of the ECO bus buffer patterns, in addition to the number of ECO bus buffer pattern, that were removed.

By default, the command reports only the number of ECO bus buffer patterns that were removed.

Description

Removes the specified ECO bus buffer patterns.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes all ECO bus buffer patterns with names that start with "or2t".

```
prompt> remove_eco_bus_buffer_patterns or2t*
2
```

See Also

- create_eco_bus_buffer_pattern
- get_eco_bus_buffer_patterns
- report_eco_bus_buffer_patterns

---

remove_eco_repeater

Remove buffer cells.

Feedback

Syntax

```
remove_eco_repeater
cell_list
[-keep_net_name keep_net_name]
[-lib_cell_input input_pin]
[-lib_cell_output output_pin]
[-verbose]
```

Arguments

cell_list

Specifies the repeaters to remove.

-keep_net_name *keep_net_name*

Specifies the names of the net to keep. It must be connected with either input or output pin of the specified repeater to remove. This is optional.

-lib_cell_input *input_pin*

Specifies the name of the input pin to connect if the removed cell has multiple input pins. This is optional.

-lib_cell_output *output_pin*

Specifies the name of the output pin to connect if the removed cell has multiple output pins. This is optional.

-verbose

Show the verbose information. This is optional.

Description

This command removes repeaters. The input or output net of such repeater, which is specified by *keep_net_name*, will be kept. The other input or output net will be removed.

This command will specify the input pin for multiple inputs cells and output pin for multiple outputs cell with the option *lib_cell_input* or *lib_cell_output*. The kept net must connect with either the specified input pin or output pin.

This command support transparent interface optimization(TIO) flow, which can remove buffer cells in sub blocks of abstract view from top block.

This command supports editing a verilog module in the module aspect, through *edit_module*.

This command will check the editability of the block before removing buffer cells.

This command honors design.eco_freeze_silicon_mode. When this app option is true, buffers to remove will be marked as spare cell and renamed by adding _Spare post-fix, instead of being removed from database.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes repeater buf1. Its input net will be kept.

```
prompt> edit_module h1m {remove_eco_repeater -keep_net_name input_net_n1
 buf1 }
```

The following example removes repeater buf1. Its output net will be kept.

```
prompt> edit_module h1m {remove_eco_repeater -keep_net_name output_net_n1
 buf1 }
```

See Also

- add_eco_repeater
- edit_module

---

remove_edit_groups

Removes edit groups from the current design.

Syntax

int *remove_edit_groups*

```
[-force]
[-verbose]
[-all]
[edit_group_list]
```

Data Types

edit_group_list list

Arguments

`-force`

Ignore locked status of the objects. If this option is not provided and any of the affected objects has locked status, command will fail generating tcl error.

`-verbose`

Displays verbose deletion information.

`-all`

Removes all edit groups from the current design.

Feedback

edit_group_list

Specifies a list of edit groups to remove. The list may contain edit group names, patterns, or collections. A collection may be specified by using the *get_edit_groups* command.

Returns

The number of removed edit groups.

Description

This command removes edit groups from the current design. Note that objects that are contained by an edit group at the time of removal are not themselves removed from the design, rather they are removed from the edit group and are no longer contained within any edit group.

Examples

The following example removes edit groups named "edit_group1" and "edit_group2".

```
prompt> remove_edit_groups { edit_group1 edit_group2 }
2
```

The following example removes edit groups that match the pattern "edit_group*".

```
prompt> remove_edit_groups edit_group*
3
```

The following example removes all edit groups in the design.

```
prompt> remove_edit_groups -all
5
```

See Also

- create_edit_group
- get_edit_groups
- add_to_edit_group
- remove_from_edit_group
- report_edit_groups

---

remove_ems_rules

Removes user-defined EMS rules.

Feedback

Syntax

```
remove_ems_rules
pattern | -all
```

Data Types

pattern pattern/collection capturing EMS user-defined rules

Arguments

pattern

This is a mandatory argument. It can be the name of a rule or a pattern capturing names of multiple rules or a collection of EMS rules. EMS rules by given name or matching given pattern or part of collection, should be already available in EMS memory; otherwise the command will fail with an error message. Option -all and argument "pattern" are mutually exclusive. If the EMS rules have messages instantiated for them then such rules are not removed.

-all

This is a mandatory option. This is mutually exclusive with argument "pattern". This option removes all user-defined rules in current EMS memory. Again if there are messages which have been created for the EMS rules then such rules are not removed.

Description

Command *remove_ems_rules* removes the user-defined rules if they do not have EMS messages created for them already.

Examples

```
prompt> create_ems_database abc.ems
prompt> create_ems_rule -name "TEMP-001" -severity "Info" -message
 "Pin:%pin has capacitance:%cap"
prompt> create_ems_rule -name "TMP-002" -severity "Error" -message "Cell
 %cell is not placed"
prompt> remove_ems_rules "TEMP-001"
prompt> create_ems_message -rule "TMP-002" -parameters "cell:U1"
prompt> remove_ems_rules "TMP-002"
Warning: Failed to remove EMS rules. (EMS-142)
```

See Also

- create_ems_rule
- create_ems_message
- create_ems_database

Feedback

remove_environment

Remove a predefined analysis environment.

Syntax

status *remove_environment*

```
-name environment_name_string
```

Data Types

```
environment_name_string  string
```

Arguments

```
-name environment_name_string
```

The analysis environment to be removed.

Description

This command removes an existing analysis environment.

Here is an example:

```
create_environment -name env1 -libset libsetA -op_conds TT
remove_environment -name env1
Information: Environment env1 is deleted. (LRE-4005)
```

See Also

- create_environment
- report_environments

remove_failsafe_fsm_groups

Removes failsafe FSM groups from the current design.

Syntax

status *remove_failsafe_fsm_groups*

```
[objects]
[-all]
```

Data Types

```
objects                    collection
```

Feedback

Arguments

objects

Specifies the group objects or names which need to be removed.

-all

Removes all the failsafe_fsm_group objects defined in the current design.

Description

Removes (deletes) the specified group objects from the current design.

Examples

The following example creates a collection of failsafe_fsm_group objects and then deletes them.

```
prompt> remove_failsafe_fsm_groups [get_failsafe_fsm_groups group1*]
```

See Also

- create_failsafe_fsm_group
- report_failsafe_fsm_groups

---

remove_failsafe_fsm_rules

Removes failsafe FSM rules from the design.

Syntax

status *remove_failsafe_fsm_rules*

```
[objects]
[-all]
[-from pins]
```

Data Types

```
objects                    collection
pins                    collection
```

Arguments

objects

Specifies the rule objects or names which need to be removed.

-all

Removes all the failsafe_fsm_rule objects defined in the current design.

Feedback

`-from` *pins*

Dissociates the failsafe_fsm_rule objects from the specified registers represented by output pins. In other words, it deletes the rule-FSM association.

Description

Removes the specified rule objects from the design. If the specified rules are being referenced by any failsafe_fsm_group, the command errors out with an appropriate warning.

Examples

The following example creates a collection of failsafe_fsm_rule objects and then deletes them.

```
prompt> remove_failsafe_fsm_rules [get_failsafe_fsm_rules rule1*]
```

See Also

- create_failsafe_fsm_rule
- report_failsafe_fsm_rules

---

remove_feasibility_constraints

Removes constraints from timing paths that were added by feasibility constraint files.

Syntax

status *remove_feasibility_constraints*

`-input_dir` *dir_name*

Data Types

dir_name string

Arguments

`-input_dir` *dir_name*

Specifies the name of the directory *dir_name* that contain the feasibility constraint files.

Description

The *remove_feasibility_constraints* command removes the timing constraints added to the current design by the feasibility constraints files. It uses the files present in the specified directory to revert back the design before these files was applied to it.

Feedback

A *input_dir* is required to be specified for the command to be able to remove the feasibility constraints applied to the current design.

Examples

The following example removes the timing constraints added by write_feasibility_constraints.

```
prompt> remove_feasibility_constraints -input_dir Multicycle_Path_2
```

See Also

- write_feasibility_constraints

---

remove_feature_tables

Removes single or multiple feature tables.

Syntax

status *remove_feature_tables*

```
-tables list_of_table_names
-all_tables
```

Data Types

list_of_table_names	list

Arguments

`-tables` *list_of_table_names*

Specifies the names of the feature tables to be removed.

`-all_tables`

Removes all feature tables. This option is mutually exclusive with *-tables*

Description

This command removes the specified feature tables. The specified tables must exist.

Examples

The following example shows the command removes feature tables by name.

```
prompt> remove_feature_tables -tables {table1 table2}
```

The following example shows the command removes all feature tables.

```
prompt> remove_feature_tables -all_tables
```

Feedback

See Also

- create_feature_table
- update_feature_table
- save_feature_tables
- read_feature_tables

---

remove_feedthroughs

Removes feedthrough ports and nets from blocks.

Syntax

string *remove_feedthroughs*

```
[-cells cell_collection]
[-nets net_collection]
[-include_original_feedthroughs]
```

Data Types

```
cell_collection  collection
net_collection   collection
```

Arguments

`-cells cell_collection`

Specifies the blocks from which to remove feedthrough ports and nets. By default, the command removes feedthroughs from all blocks.

`-nets net_collection`

Specifies the nets from which to remove feedthrough ports. By default, the command removes feedthroughs from all nets.

`-include_original_feedthroughs`

Removes the original feedthrough ports and new feedthrough ports that are created by the *place_pins* command. If you specify this option, the tool removes these feedthrough ports and the connections to these ports at the top level. By default, the command preserves the original ports and their top level connections.

Description

This command removes feedthrough ports and nets that exist within the design. By default, the command removes all added feedthrough nets and ports, and preserves all original nets and ports, for all blocks. To apply the command to a specific set of nets, use

Feedback

the *-nets* option to specify a collection of nets. To apply the command to certain blocks, use the *-cells* option to specify a collection of blocks.

The *-include_original_feedthroughs* option removes original and new feedthrough nets and ports An original port is a port on a block that is a feedthrough port in the original netlist. By default the command looks at multiple levels of physical hierarchy (MPH support) for feedthrough removal. The *set_editability* can be used to enable/disable removal on individual reference-blocks or levels of physical hierarchy. If a net is connected to even a single instance that is disabled for design planning such a net will be skipped for feedthrough removal.

All the redundant feedthroughs in the whole design will always be removed, as long as the parent block of the redundant feedthrough is enabled for design planning.

Examples

The following example removes feedthrough nets and ports on all nets and all blocks, for both new and existing feedthroughs.

```
prompt> remove_feedthroughs -include_original_feedthroughs
```

See Also

- place_pins
- report_feedthroughs
- set_editability

---

remove_fill_cells

Removes the specified fill cells from the current block.

Syntax

```
status remove_fill_cells
   [-remove_reference]
   [-all]
   [fill_cell_list]
```

Data Types

```
fill_cell_list     list
```

Arguments

`-remove_reference`

Remove the reference internal designs of the specified fill cells, if unused after removing the fill cells.

Feedback

fill_cell_list

Specifies the fill cells to remove.

The *fill_cell_list* argument and *-all* option are mutually exclusive; you must specify one.

-all

Removes all fill cells from the current block.

The *-all* option and *fill_cell_list* argument are mutually exclusive; you must specify one.

Description

Removes the specified fill cells from the current block.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example removes the fill cells whose name includes "_1".

```
prompt> get_fill_cells *_1*
{FILL_INST_1 FILL_INST_10}

prompt> remove_fill_cells -remove_reference *_1*
2
```

See Also

- get_fill_cells

---

remove_floorplan_rules

Removes the floorplan rules in the design.

Syntax

status *remove_floorplan_rules*

```
[-object_types type_list]
[-lib_cells lib_cells]
[-all]
[rule_list]
```

Feedback

Data Types

```
type_list  list
lib_cells  collection
rule_list  list
```

Arguments

`-object_types` *type_list*

Specifies the list of object types for which some floorplan rules are defined. Floorplan rules that have specified object types in their *-from_object_types* or *-to_object_types* or *-object_types* will be removed. Valid values for this option are *block_boundary*, *core_area*, *hard_macro*, *placement_blockage*, *routing_blockage*, *shape*, *soft_macro* and *std_cell_area*. This option is mutually exclusive with the *-all* and *rule_list* options.

`-lib_cells` *lib_cells*

Specifies the collection of library cells for which some floorplan rules are defined. Floorplan rules that have specified library cells in their *-from_lib_cells* or *-to_lib_cells* or *-lib_cells* will be removed. This option is mutually exclusive with the *-all* and *rule_list* options.

`-all`

Removes all floorplan rules defined in the design. This option is mutually exclusive with the *-object_types*, *-lib_cells* and *rule_list* options.

rule_list

Specifies the list of floorplan rule names to remove. This option is mutually exclusive with the *-object_types*, *-lib_cells* and *-all* options.

Description

The *remove_floorplan_rules* command removes existing floorplan rules in a design based on specified input parameters. On successful removal, the command returns a status of 1.

The *rule_list* option is mutually exclusive with the *-object_types*, *-lib_cells* and *-all* options. If any named rule in *rule_list* does not exist or no rule exists for the given object types or library cells, a warning is issued.

Examples

The following example tries to remove two floorplan rules named e2 and ab. The floorplan rule ab does not exist.

```
prompt> remove_floorplan_rules {e2 ab}

Warning: Floorplan rule 'ab' does not exist.
0
prompt> report_floorplan_rules e2
```

Feedback

```
Warning: Floorplan rule 'e2' does not exist.
0
```

The following example tries to remove floorplan rules for object type std_cell_area and library cell lc4. Since no floorplan rule exists for library cell lc4, the command issues a warning message and removes floorplan rule e2 for object type std_cell_area.

```
prompt> remove_floorplan_rules -object_types std_cell_area -lib_cells \\
   [get_lib_cells */lc4]

Warning: No floorplan rules exists for given lib cells.
1
prompt> report_floorplan_rules e2
Warning: Floorplan rule 'e2' does not exist.
0
```

See Also

---

remove_from_bound

Unassigns cells and ports from a bound in the current design.

Syntax

int *remove_from_bound*

```
bound_object
cell_and_port_list
```

Data Types

```
bound_object       list
cell_and_port_list list
```

Feedback

Arguments

bound_object

Specifies the name or collection of a single bound. The bound object can be specified by using the *get_bounds* command. However it must return a collection of one bound object.

cell_and_port_list

Specifies a list of cells and ports to unassign from the bound. The list may contain names, patterns, or collections. If a cell or port is not assigned to the bound, it is skipped and not removed. Cells that are implicitly in the bound (because its parent hierarchical cell is the bound) cannot be unassigned from the bound. Only assigned cells may be unassigned. However such cells may be assigned to a different bound using the *add_to_bound* command.

Description

The *remove_from_bound* command unassigns cells and ports from an existing bound, which are currently assigned to the bound.

You can readjust the utilization by unassigning cells from the bound. The placer assumes that the cells are no longer constrained by placement bounds.

Examples

The following example unassigns all cells from a bound named "movebound1".

```
prompt> remove_from_bound movebound1 *
1
```

The following example unassigns a hierarchical cell from a bound named "movebound2".

```
prompt> remove_from_bound movebound2 mid
1
```

See Also

- create_bound
- get_bounds
- add_to_bound
- report_bounds
- remove_bounds

Feedback

remove_from_bundle

Removes one or more objects from the specified bundle.

Syntax

```
status_value remove_from_bundle
-bundle bundle
[-all]
object_list
```

Data Types

```
bundle       collection
object_list  list
```

Arguments

`-bundle` *bundle*

Specifies the bundle to remove object from.

`-all`

Removes all occurrences of the specified object from the bundle. By default, only the first occurrence of the object is removed.

object_list

Specifies the list of objects to remove from the bundle.

Description

Removes a list of objects from the specified bundle.

Examples

The following example removes objects from a bundle.

```
prompt> remove_from_bundle -bundle [get_bundles BUNDLE_5] [get_nets Clk]
1
```

See Also

- add_to_bundle
- create_bundle
- get_bundles
- remove_bundles
- report_bundles

Feedback

remove_from_collection

Removes objects from a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *remove_from_collection*

```
[-intersect]
collection1
object_spec
```

Data Types

collection1	collection
object_spec	list

Arguments

`-intersect`

Removes objects from collection1 not found in object_spec. Without this option, removes objects from collection1 that are found in object_spec.

collection1

Specifies the base collection to be copied to the result collection. Objects matching *object_spec* are removed from the result collection.

object_spec

Specifies a list of named objects or collections to remove. The object class of each element in this list must be the same as in the base collection. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

Description

The *remove_from_collection* command removes elements from a collection, creating a new collection.

If the base collection is homogeneous, any element of the *object_spec* that is not a collection is searched for in the database using the object class of the base collection. If the base collection is heterogeneous, any element of the *object_spec* that is not a collection is ignored.

If the *-intersect* option is not specified, which is the default mode, and if nothing matches the *object_spec*, the resulting collection is a copy of the base collection. If everything in the *collection1* option matches the *object_spec*, the result is the empty collection. With the *-intersect* option the results are reversed.

Feedback

For background on collections and querying of objects, see the *collections* man page.

Examples

The following example from PrimeTime gets all input ports except "CLOCK".

```
pt_shell> set cPorts [remove_from_collection [all_inputs] CLOCK]
{"in1", "in2"}
```

See Also

- add_to_collection
- collections

---

remove_from_edit_group

Removes objects from an edit group in the current design.

Syntax

int *remove_from_edit_group*

```
edit_group_object
object_list
```

Data Types

```
edit_group_object   list
object_list         list
```

Arguments

edit_group_object

Specifies the name or collection of a single edit group. The edit group object can be specified by using the *get_edit_groups* command, however, it must return a collection of exactly one edit group object.

object_list

Specifies a list of objects to remove from the edit group. The list can contain names, patterns, or collections. Objects which are not contained in the edit group are skipped.

Description

The *remove_from_edit_group* command removes objects from an existing edit group.

The command returns a collection containing the modified edit group as the only object, or an empty collection if the edit group was removed due to its ungroup_on_remove attribute setting. If the command fails, it return a Tcl error.

Feedback

Examples

The following example removes all shapes from an edit group named "edit_group1".

```
prompt> remove_from_edit_group edit_group1 [get_shapes]
{"edit_group1"}
```

---

remove_from_group

Removes objects from the group in the current design.

Syntax

int *remove_from_group*

```
group
object_list
```

Data Types

```
group          list
object_list    list
```

Arguments

group

Specifies the name or collection of group. The group object can be specified by using the *get_groups* command.

object_list

Specifies a list of objects to remove from the group. The list can contain names, patterns, or collections. Removing an object which is not a member of the group is an error.

Returns

The number of object removed the group or TCL_ERROR if the command fails.

Feedback

Description

The *remove_from_group* command removes objects from the group.

Examples

The following example removes shape R1 from group named "group1".

```
prompt> remove_from_group group1 [get_shapes R1 ]
1
```

---

remove_from_io_guide

Removes pad cells from an I/O guide in the current design.

Syntax

int *remove_from_io_guide*

```
io_guide_object
pad_cell_list
```

Data Types

```
io_guide_object       list
pad_cell_list         list
```

Arguments

io_guide_object

Specifies the name or collection of a single I/O guide. The *io_guide_object* can be specified with the *get_io_guides* command, however, it must return a collection of one I/O guide object.

pad_cell_list

Specifies a list of pad cells to remove from the I/O guide. The list can contain names, patterns, or collections. If a cell or port is assigned to another I/O guide, it is skipped and not removed.

Feedback

Description

The *remove_from_io_guide* command removes pad cells from an existing I/O guide. The command returns 1 if successful, 0 if it fails, or a Tcl error if there is a command syntax error.

Examples

The following example removes all cells from a I/O guide named "io_guide1".

```
prompt> remove_from_io_guide io_guide1 *
1
```

See Also

- add_to_io_guide
- create_io_guide
- get_io_guides
- remove_io_guides
- report_io_guides

---

remove_from_io_ring

Removes I/O guides from an I/O ring in the current design.

Syntax

int *remove_from_io_ring*

```
io_ring_object
guide_list
```

Data Types

```
io_ring_object     list
guide_list         list
```

Arguments

io_ring_object

Specifies the name or collection of a single I/O ring. The *io_ring_object* can be specified by using the *get_io_rings* command. However it must return a collection of one I/O ring object.

Feedback

guide_list

Specifies a list of I/O guides to remove from the I/O ring. The list can contain names, patterns, or collections. If a cell or port is assigned to another I/O ring, it is skipped and not removed.

Description

The *remove_from_io_ring* command removes I/O guides from an existing I/O ring. The command returns 1 if the successful, 0 if it fails, or a Tcl error if there is a command syntax error.

Examples

The following example removes all I/O guides from a I/O ring named "io_ring1".

```
prompt> remove_from_io_ring io_ring1 *
1
```

See Also

- add_to_io_ring
- create_io_ring
- get_io_rings
- remove_io_rings
- report_io_rings

---

remove_from_matching_type

Removes cells, pins, and terminals from the matching type.

Syntax

int *remove_from_matching_type*

```
[-auto_fix]
matching_type
object_list
```

Data Types

```
matching_type       list
object_list         list
```

Feedback

Arguments

`-auto_fix`

Removes non-existent objects from the matching type. Objects become non-existent when reference libraries or designs are modified, and objects no longer exist in the cell hierarchy.

The *-auto_fix* and *object_list* options are mutually exclusive; you can specify only one of them.

`matching_type`

Specifies the name or collection of a single matching type. The matching type can be specified by using the *get_matching_types* command. However it must return a collection of one matching type.

`object_list`

Specifies a list of cells, pins, and terminals to remove from the matching type. The list may contain names, patterns, or collections. If an object is not in the matching type, it is skipped and not removed.

The *-auto_fix* and *object_list* options are mutually exclusive; you can specify only one of them.

Description
