Fusion Compiler Tool Commands

This document describes the tool commands supported by the Fusion Compiler tool.

a

add_array_to_macro_group

Add macro array to macro group.

Syntax

```
status add_array_to_macro_group
-group macro_group
-array macro_array
```

Arguments

`-macro_group macro_group`

Specifies macro group.

`-macro_array macro_array`

Specifies macro array.

Description

This command add macro array to macro group. All macros of the macro array will be added to the macro group. If the macro array belongs to another macro group before this command, it will be removed from that macro group and added to the new macro group. If the macro group contains macros before the command, those macros and macros of the macro group must belong to the same placeable area, i.e, movebound, voltage area, or block.

Examples

The following command add macro array array1 to micro group group1

```
prompt> add_array_to_macro_group -group group1 -array array1
```

Feedback

See Also

- remove_array_from_macro_group
- add_macro_to_group
- remove_macros_from_group
- create_macro_array

---

add_attachment

Adds user-defined attachments on a library or a design.

Syntax

status *add_attachment*

```
name
-file_name
-object
```

Data Types

```
name     string
```

Arguments

`name`

Specifies the name of the attachment.

`-file_name`

Specifies the name of the file to be attached.

`-object`

Specifies a library or a design object. A cell library should be used only in Library Manager Shell. Library cells cannot have attachments.

Description

This command adds an attachment to the given library or design. The attachment is always a file and after you attach the file to the given object, a copy of the file is taken into the database and completely managed by the tool.

Examples

In the following example an attachment is added to the current block.

Feedback

```
prompt> add_attachment -object [current_block] -file_name test_att.txt
 test_att
1
```

See Also

- remove_attachments
- report_attachments
- open_attachment

---

add_buffer

Adds buffer cells on the nets that are connected to the specified pins.

Syntax

collection *add_buffer*

```
[-new_net_names new_net_names]
[-new_cell_names new_cell_names]
[-inverter_pair]
[-no_of_cells number]
object_list
[-lib_cell buffer_lib_cell] | [buffer_lib_cell]
[-snap]
[-respect_voltage_areas]
```

Data Types

new_net_names	list
new_cell_names	list
number	integer
object_list	list
buffer_lib_cell	collection

Arguments

`-new_net_names` *new_net_names*

Specifies the names of the new nets to add. You must specify one net name per buffer when adding buffers, and two net names per inverter pair when adding inverter pairs. If the specified net name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the net name.

Optionally, if you specify only the common base name, the tool generates new net names by adding unique numeric suffixes to the common base name. The specified names can be any valid net names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical

Feedback

separators. They must be unique in the current context, as specified by the current instance. By default, the command uses the base name eco_net.

`-new_cell_names` *`new_cell_names`*

Specifies the names of the new cells to be added. You must specify one cell name per buffer when adding buffers, and two cell names per inverter pair when adding inverter pairs. If the specified cell name already exists, the command adds a suffix of "_%d" or "_%d_%d" to the cell name.

Optionally, if you specify only the common base name, the tool generates new cell names by adding unique numeric suffixes to the common base name. These names can be any valid cell names, but must be the leaf names. They must not be the hierarchical names and must not contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance.

By default, the command uses *eco_cell* as the common base name.

`-inverter_pair`

Adds inverter pairs instead of buffer cells. If you specify this option, you must supply a library cell that has an inverting output. You can use this option when the specified library cell or buffer has both inverting and noninverting outputs.

`-no_of_cells` *`number`*

Specifies the number of buffer cells or inverter pairs to be inserted per net. The inserted repeaters are connected back-to-back in series. By default, the command inserts a single buffer cell or inverter pair per net.

`object_list`

Specifies a list of nets, pins, or ports that must be buffered. The new buffer cells or inverter pairs are placed close to the specified pins or ports if their cells are placed.

If you specify a net, the tool connects the buffers or inverter pairs such that a new buffer cell is the new load of the original net.

If you specify pins, the tool groups all of the specified pins based on the nets to which they are connected. When the grouped pins are load pins, the tool adds the buffers so that the new buffer cells can drive them. When the grouped pins are driver pins, the tool connects the new buffer cells so that they become the load of the specified driver pin.

`-lib_cell` *`buffer_lib_cell`*

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. This is a required option. This option is mutually exclusive with *buffer_lib_cell*.

Feedback

If the library cell has both inverting and noninverting outputs, that is, it can act both as buffer and inverter, the *-inverter_pair* option controls which output is used. If the library cell has multiple outputs, the command uses the first noninverting or inverting output.

buffer_lib_cell

This positional option is exactly equivalent to -lib_cell. And it is mutually exclusive with *-lib_cell*.

`-snap`

Put the new buffer cells next to the target cell, then snap the buffer cells to the closest site, and flip the buffer cells when needed.

If you specify a net or a driver pin with this option, the new buffer cells are placed next to the target cell of driver pin if the target cell are placed.

If you specify a load pin with this option, the new buffer cells are placed next to the target cell of load pin if the target cell are placed.

If you specify a list of load pins on the same net with this option, the new buffer cells are placed in the center of all load pins if the target cell are placed.

This option is mutually exclusive with the *-respect_voltage_areas* option.

`-respect_voltage_areas`

Inserts buffers within the hierarchy of the voltage area such that the buffer is physically in the layout. This option is mutually exclusive with the *-snap* option.

Description

This command adds buffers or inverter pairs at one or more specified pins or ports. A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

Like all other netlist editing commands, the command arguments to *add_buffer* must be valid for the command to run successfully. If the command succeeds, the result is a collection of the newly-added cells. If the command fails, the command returns an empty collection or an empty string and does not change the netlist.

By default, each newly-created cell has a name beginning with the eco_cell string and ending with a unique numeric suffix. Each newly-created net has a name beginning with the eco_net string and ending with a unique numeric suffix. To override the automatic name generation by the tool, use the *-new_net_names* and *-new_cell_names* options.

You can mimic buffer addition by using other commands, such as *create_cell*, *create_net*, *disconnect_net*, and *connect_net*. The *add_buffer* command provides a more efficient and safe way to add buffers.

Feedback

This command support editing a Verilog module in the module aspect, through *edit_module*.

This command checks if the block is editable before adding buffer cells.

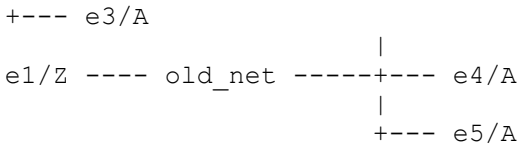
This command honors the *design.eco_freeze_silicon_mode* application option. When this application option is *true*, the *is_fs_eco_add* attribute of the added buffers is set to *true*.

The *add_buffer* command uses the following basic rules to check its arguments for validity:

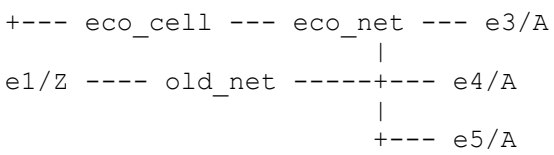
- The pin or port must be in scope; that is, at or below the current instance. For a description of special scoping rules, see the "Buffering Inside Boundary Pins" section.
- The pin or port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The net cannot be either a PG net or a tie net.
- The specified library cell cannot be sequential.
- The specified library cell must be a buffer, as previously defined.
- The *number* argument of the *-no_of_cells* option must be a positive, nonzero integer.
- The library cell must have an inverting output, when you use the *-inverter_pair* option. The command uses the first inverting output and adds two cells so that it preserves the logic of the path.

Adding and Connecting the New Buffer

The following figure shows an example network that is used to describe the rules used by the *add_buffer* command to connect the new buffer or inverter pair:



If the specified pin is a load, the load is first disconnected from its old net and then connected to the new net, as shown in the following figure:



Feedback

If the specified pin is a driver, all loads on that net are disconnected from the old net and are connected to the new net, as shown in the following figure:

```
+--- e3/A
                                                |
e1/Z --- old_net --- eco_cell --- eco_net -+--- e4/A
                                                |
                                                +--- e5/A
```

If you specify a list of load pins on the same net, these load pins are grouped and the new net drives them, as shown in the following figure:

```
+--- e3/A
                    |
e1/Z --- old_net -+- eco_cell --- eco_net -+--- e4/A
                                                |
                                                +--- e5/A
```

Note that the tool cannot buffer a net driven by multiple drivers.

Buffering Inside Boundary Pins

When you use this command to add a buffer at a pin on the boundary of a hierarchical block, the command adds the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To add the buffer inside the hierarchical block, set the scope to that block by using the *current_instance* command, and then run the *add_buffer* command. The tool adds the buffer within the block to which the *current_instance* is set.

Don't touch support for nets

When application option *eco.add_buffer.honor_dont_touch* is set to true, nets with dont_touch attribute are skipped.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example specifies a library cell that is not a buffer. The command fails and generates an error message.

```
prompt> add_buffer e1/Z -lib_cell class/AN2P
Information: Buffering net old_net. (HFS-701)
Error: library cell 'AN2P' is not a buffer or an inverter. (ECOUI-010)
```

The following example specifies a buffer for the library cell:

```
prompt> add_buffer e1/Z -lib_cell class/B1I
{eco_cell}
```

Feedback

The following example specifies an inverter for the library cell. The command succeeds and creates the new cells named *eco_cell* and *eco_cell_1*. The new nets are named *eco_net* and *eco_net_1*. The *report_cells* command displays the connections for cell e3.

```
prompt> add_buffer e3/A -lib_cell class/IV -inverter_pair
{eco_cell eco_cell_1}

prompt> report_cells -connections e3
****************************************
Report : cell
 -connections
****************************************

Connections for cell 'e3':
 Reference:   B1I
 Library:     class

 Input Pins         Net
 ----------------   ------------
 A                  eco_net

 Output Pins        Net
 ----------------   ------------
 Z                  out2

1
prompt> report_nets -connections eco_net
****************************************
Report : net
 -connections
****************************************

Connections for net 'eco_net':

 Driver Pins        Type
 ------------       -----------------
 eco_cell/Z         Output Pin (IV)

 Load Pins          Type

[-verbose]
```

Data Types

list_of_nets	list
buffer_lib_cell	string
prefix	string
coordinate_list	list
user_specified_buffer_list	list
length	float
user_specified_bus_buffer_list	list
bus_cell_prefix_list	list
length_ratio	float
layer_scale_list	list
cell_list	list
supply_net	string
voltage_area_specific_lib_cell_list	list
voltage_areas	collection
mv_aware_lib_cell_list	list
layer_cutting_distance_list	list

Arguments

list_of_nets

Specifies the nets to be buffered. If *-user_specified_buffers* or *-location* is used, this option must specify only a single net name.

-lib_cell *buffer_lib_cell*

Specifies the library cell object to use as a repeater. The object is either a named library cell or a library cell collection.

The library cell must be either buffer or inverter. The command automatically determines the type of the library cell and inserts buffer or inverter pairs on routes based on the type.

This option cannot be used with the *-user_specified_buffers* or *-user_specified_bus_buffers* options. If *-location*, *-repeater_distance* or *-repeater_distance_length_ratio* is specified, this option must also be specified.

buffer_lib_cell

This positional option is exactly equivalent to the *-lib_cell* option. This option is mutually exclusive with the *-lib_cell* option.

Feedback

`-net_prefix` *`prefix`*

Specifies the prefix to be used for new nets that are created when buffers are inserted in the netlist. By default, the command uses "eco_net" as the prefix.

`-cell_prefix` *`prefix`*

Specifies the prefix to be used for new buffers that are inserted in the netlist. By default, the command uses "eco_cell" as the prefix. This option cannot be used with the *-user_specified_buffers* option.

`-location` *`coordinate_list`*

Specifies the center point coordinates for the locations of the buffer or inverter pair cells. The format is:

```
{x1 y1 layer1 x2 y2 layer2 ...}
```

You must specify one location per buffer when inserting buffers. You must specify two locations per inverter pair when inserting inverter pairs. These locations can be any valid {x_coordinate y_coordinate layer_name} triplet that is not far away from the placement region of the core area and is relative to the chip origin. These locations must be within a region from the route. The region radius is specified by the *-max_distance_to_route* option. Specify the coordinates in user units. More than one routing shape can overlap the specified location. The layer is used to decide which shape to pick.

- If you specify a valid name for the layer, the location is matched on a routing shape on the specified layer.
- If you specify the *-detect_layer* option, the coordinate_list must use the format {x1 y1 x2 y2}, with no layer name specification. The command tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the command writes out an error message and exits.

For best results, specify the explicit layer instead of using the *-detect_layer* option.

`-user_specified_buffers` *`user_specified_buffer_list`*

Specifies the center point coordinates for the locations of the buffer or inverter pair cells, as well as their names and library cells. The format is:

```
{name1 lib_cell1 x1 y1 layer_name1 name2 lib_cell2 x2 y2
 layer_name2 ...}
```

You must specify one five-tuple per buffer when inserting buffers. You must specify two five-tuples per inverter pair when inserting inverter pairs. The names should be valid name strings for buffers or inverters. The library cells should be name strings or collections. They can be all inverters, all buffers or buffers/

Feedback

inverters mixed. When input mixed buffers/inverters, the inverters must be pairs in each branch path. The locations can be any valid coordinates with layers that are not far away from the placement region of the core area and are relative to the chip origin. These locations must be within a region from the route. The region is specified by *-max_distance_to_route*. Specify the coordinates in user units. More than one routing shape can overlap the specified location. The layer is used to decide which shape to pick. This option cannot be used with the *-lib_cell* or *-voltage_area_specific_lib_cells* options.

- If you specify a valid name for the layer, the location is matched on a routing shape on the specified layer.
- If you specify the *-detect_layer* option, the user_specified_buffer_list must use the format { name1 lib_cell1 x1 y1 name2 lib_cell2 x2 y2 }, with no layer name specification. The command tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the command writes out an error message and exits.

For best results, specify the explicit layer instead of using the *-detect_layer* option.

`-max_distance_to_route` *`length`*

Specifies the maximum horizontal or vertical distance in user units between the specified location and route. The default for this option is five times the height of reference cell. You can use this option only if you also use the *-location* or *-user_specified_buffers* option.

`-detect_layer`

Specifies that the tool detects the layer of location coordinates automatically. The tool tries to find the nearest routing shape. If there are two routing shapes in different metal layers that are the same distance from the specified location, the tool errors out. When this option is used, the coordinate_list uses the format {x1 y1 x2 y2} or {name1 lib_cell1 x1 y1 name2 lib_cell2 x2 y2}, no layer name specified.

You can use this option only if you also use the *-location* or *-user_specified_buffers* option.

`-user_specified_bus_buffers` *`user_specified_bus_buffer_list`*

Specifies the center point coordinates for the locations of bus buffer or inverter pair cells, as well as their names and library cells, using the format {*bus_buffer_pattern1 lib_cell1 x1 y1 bus_buffer_pattern2 lib_cell2 x2 y2* ...}. You must specify one four-tuple per buffer added on each bit at a location. You must specify two four-tuples per inverter pair when inserting inverter pairs. The *bus_buffer_patterns* should be name strings or collections created by

Feedback

the *create_eco_bus_buffer_pattern* command. The library cells should be name strings or collections. They must be either all inverters or all buffers. The locations can be any valid coordinates that are inside the placement region of the core area and are relative to the chip origin. These locations must be within routes of the bus. Routes of all bits near this point must be parallel and match style (horizontal or vertical) of the specified pattern. For horizontal routes, the center of the bus buffer pattern is located at the x of the specified location. For vertical routes, the center of the bus buffer pattern is located at the y of the specified location. And routes of all bits near this point must be in same situation (For example, same VA, not over blockage/macro). Specify the coordinates in units of user unit.

This option cannot be used with the *-repeater_distance*, *-repeater_distance_length_ratio*, *-location* or *-user_specified_buffers* options. This option cannot be used with the *-lib_cell* or *-voltage_area_specific_lib_cells* options.

`-bus_cell_prefix` *`bus_cell_prefix_list`*

Specifies the prefix to be used for new buffers that are added by the *-user_specified_bus_buffers* option.

If this option not specified, or the pattern of bus buffers are not listed in *bus_cell_prefix_list*, tool uses the prefix specified by *-cell_prefix*. If *-cell_prefix* is also not specified, default prefix is given name of the bus buffer pattern

You can use this option together with the *-user_specified_bus_buffers* option.

`-repeater_distance` *`length`*

Specifies the distance in user units between each buffer to be inserted along the route. This option applies to the entire physical route for the specified nets.

`-repeater_distance_length_ratio` *`length_ratio`*

Specifies the distance between each buffer that is inserted along the route as a ratio of the total route length. The value range is between 0.0 and 1.0. This option applies to the entire physical route for the specified nets.

Only one of the *-location*, *-user_specified_buffers*, *-user_specified_bus_buffers*, *-repeater_distance*, or *-repeater_distance_length_ratio* options should be specified.

`-first_distance` *`length`*

Specifies the distance in user units between the driver pin and the first buffer introduced along the route. This option must be used together with the *-repeater_distance* or *-repeater_distance_length_ratio* option.

Feedback

`-first_distance_length_ratio` *`length_ratio`*

Specifies the distance between the driver pin and the first buffer introduced along the route as a ratio of the total route length. The value range is between 0.0 and 1.0. This option must be used together with the *-repeater_distance_length_ratio* option.

`-last_distance` *`length`*

Specifies the distance in user units between the load pin and the last buffer introduced along the route. This option must be used together with the *-repeater_distance* or *-repeater_distance_length_ratio* option. This option cannot be used with the *-locaton* or *-user_specified_buffers* or *-user_specified_bus_buffers* option.

`-scaled_by_layer` *`layer_scale_list`*

Scales the distance between buffers by the scaling factor specified for the layer. Specify the scaling factors by using the following format:

`{{`*`layer1 factor1`*`} {`*`layer2 factor2`*`} ...}`

The command scales the distance on each layer with the following formula:

```
D = d*L_M

d:the repeater distance
D:the repeater scaled distance
L_M:layer scaling factor on metal M
```

Layers that are not in the list use a default factor of 1. You must specify this option together with the *-repeater_distance* option.

`-scaled_by_width`

Scales the distance between buffers by the ratio of the default width for the layer and the actual route width. This option is mutually exclusive with the *-only_global_routed_nets* option.

The command scales the distance on each layer with the following formula:

```
D = d*w_M/w_R

d:the repeater distance
D:the repeater scaled distance
w_M:default route width on metal M
w_R:actual route width
```

By default, the scaling factor is 1 (w_M=w_R). You must specify this option together with the *-repeater_distance* option.

Feedback

`-only_global_routed_nets`

Enable buffer insertion on global routed nets. When this option is used, the specified nets must be only global routed without track assignments or detail routes. This option is mutually exclusive with the *-scaled_by_width* option.

`-respect_blockages`

Specifies that no buffer should be added within a placement blockage, soft macro, or hard macro.

`-allow_insertion_over_cell` *`cell_list`*

Specifies the soft macro or hard macro instances in which the repeaters can be added. This option must be used together with the *-respect_blockages* option.

`-dont_allow_insertion_over_cell` *`cell_list`*

Specifies the soft macro or hard macro instances in which the repeaters are not allowed. This option is mutually exclusive with the *-respect_blockages* option.

`-max_distance_for_incomplete_route` *`length`*

Defines the maximum search distance for incomplete routes. By default, the search distance is one repeater height.

`-snap_to_sites`

Snaps the newly added buffers to the nearest sites.

`-punch_port`

Enables buffer insertion on a route segment, even when the topology is different than the netlist connection in the logical hierarchy. In this situation, the tool creates a hierarchical port to connect the loads of the buffer. This option is mutually exclusive with the *-respect_voltage_areas*, *-voltage_area_specific_lib_cells* and *-respect_gas_station* options.

`-respect_gas_station` *`supply_net`*

Buffers are only added within gas stations (whose is_primary attribute is false) for the specified *supply_net* and along the routes. The buffers that are inserted belong to the gas station. This option automatically enables the *-respect_voltage_areas* option. This option is mutually exclusive with the *-punch_port* option.

`-max_distance_route_to_gas_station` *`length`*

Specifies the distance between the gas station in which the buffer is added the route. If this option is not specified, gas stations must be on the route.

Feedback

`-respect_voltage_areas`

Inserts buffers within the hierarchy of the voltage area such that the buffer is physically inside hierarchy in the layout. When this option is specified, buffers cannot be added outside core area. This option is mutually exclusive with the *-punch_port* option.

`-voltage_area_specific_lib_cells` *voltage_area_specific_lib_cell_list*

Specifies library cell objects to be used in the specified voltage areas. The format is:

{*va1 lib_cell1 va2 lib_cell2 ...*}

For the default voltage area, specify DEFAULT_VA as the voltage area name. If a buffer is added within a voltage area that is not specified by this option, the lib cell specified by *-lib_cell* is used. When the *-voltage_area_specific_lib_cells* is specified, buffers cannot be added outside core area. The *-lib_cell* option is always required when *-voltage_area_specific_lib_cells* is specified. This option automatically enables the *-respect_voltage_areas* option. This option is mutually exclusive with the *-user_specified_buffers* and *-punch_port* options.

`-allow_physical_feedthrough_buffer` *voltage_areas*

Specifies voltage areas in which buffers can be added, even if they are physical-only feedthroughs. *voltage_areas* must by a primary voltage area. This option must be used together with the *-respect_voltage_areas* or *-voltage_area_specific_lib_cells* option.

`-on_top_hierarchy`

Adds buffers to the net at the highest level of hierarchy. By default, the buffers are added in the lowest common ancestor hierarchy of the pins driven by the buffers.

`-honor_net_hierarchy`

Add buffer on current hierarchical of the given net.

`-max_distance_to_spare_cell` *length*

Specifies the maximum distance between newly added buffers and spare cells in freeze-silicon mode. If this option is not specified, the command uses the default of 5 site heights. For user-location based, buffer is inserted at the projected location on the route; there must be a compatible spare cell within the maximum search distance or the command writes out an error message and exit. For repeater distance based, the buffer is added only when there is a compatible spare cell within the maximum search distance. The newly added buffers are placed to overlap the matched spare cells and a new "fs_mapped_cell_name" attribute is added to record the mapping relationship in both buffers and spare cells. The feature of spare cell aware only works in

Feedback

freeze-silicon mode, inverter pair input and some other advanced options. This option is mutually exclusive with the *-not_spare_cell_aware* option.

`-not_spare_cell_aware`

Disables the spare cell aware feature in freeze-silicon mode. By default, this option is off. The spare cell aware feature only works in freeze-silicon mode. This option is mutually exclusive with the *-max_distance_to_spare_cell* option.

`-select_mv_buffers` *`mv_aware_lib_cell_list`*

Specifies single rail and dual rail library cell objects to be used in the specified voltage areas. The format is:

```
{va1 single_rail_lib_cell1 dual_rail_lib_cell1 \\
va2 single_rail_lib_cell2 dual_rail_lib_cell2 ...}
```

When this option is specified, command enables mv aware features. It selects the mv legal lib cell from the input list to create buffers and update supply net automatically. For the default voltage area, specify DEFAULT_VA as the voltage area name. For the voltage areas not specified by this option, command uses the lib cell specified by *-lib_cell*. This option automatically enables the *-respect_voltage_areas* option.

`-min_buffer_distance` *`length`*

If distance to previous buffer or driver plus the length of a blockage exceeds repeater distance, an additional buffer may be added before the blockage. But if the additional buffer is too close to previous buffer or driver, it will be added after the blockage. Use this option to specify how close the distance could be to previous buffer or driver. Default value is 50% of repeater distance.

`-layer_cutting_distance` *`layer_cutting_distance_list`*

Specify route cutting spacing list on both side (input and output) of the inserted repeater based on layers, distance is calculated from center of repeater to input side or output side. This option is in higher priority than app option eco.add_buffer_on_route.route_cutting_space. This option doesn't support global route shapes. The format is:

```
{{layer1 cutting_distance_in_1 cutting_distance_out_1}
 {layer2 cutting_distance_in_2 cutting_distance_out_2} ...}
```

`-verbose`

Shows verbose messages.

Description

The *add_buffer_on_route* command adds buffers along the route of the specified nets. The new buffers are placed but not legalized, and the original net and the newly created nets are not rerouted.

Feedback

The new buffers are placed close to the route of the input net. The new nets follow the original route as much as possible. You can query the new buffers by the collection *abor_new_buffers*.

A library cell with a single input and multiple outputs is a buffer, as long as each output has the same or inverted logic function as the input.

By default, each newly added buffer has a name beginning with the prefix eco_cell and ending with a numeric suffix. To override the automatic name generation by the tool, use the *-net_prefix* and *-cell_prefix* options.

This command also supports spare cell aware feature in freeze-silicon mode.

The *add_buffer_on_route* command uses the following basic rules to validate the command arguments:

- The net cannot be a PG net or a tie net.
- The net can be routed incompletely. But all routing segments must be fully interconnected and there is one and only one wire within search distance from each untouched load pin. The search distance can be specified by the *-max_distance_for_incomplete_route* option.
- The library cell cannot be sequential.
- The library cell must be a buffer or inverter, as previously defined.

This command honors the *design.eco_freeze_silicon_mode* application option. When this application option is true, the is_fs_eco_add attribute is set to true for the inserted buffers.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows the command adds buffers on net1 using the lib/BUF library cell. The repeater distance is 100 and the first distance is 80.

```
prompt> add_buffer_on_route -repeater_distance 100 \\
   -first_distance 80 net1 -lib_cell lib/BUF
```

The following example shows the command adds buffers on net1 using the lib/BUF library cell. The repeater distance is 100, the first distance is 80 and the last distance is 50.

```
prompt> add_buffer_on_route -repeater_distance 100 \\
   -first_distance 80 -last_distance 50 net1 -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. One location is specified and let command to detect layer.

Feedback

```
prompt> add_buffer_on_route -location {100 200} -detect_layer net1 \\
   -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. Both location and layer are specified.

```
prompt> add_buffer_on_route -location {100 200 METAL3} net1 \\
   -lib_cell lib/BUF
```

The following example adds buffers on net1 by using the *-user_specified_buffers* option.

```
prompt> add_buffer_on_route n1 \\
   -user_specified_buffers {eco1 bufbd2 70 10 eco2 bufbd4 140 10} \\
   -detect_layer
```

The following example adds buffers on bus data* by using the *-user_specified_bus_buffers* option.

```
prompt> add_buffer_on_route [get_nets data*] \\
   -user_specified_bus_buffers "bpuLT bufx8 x1 y1 bpuBR bufx8 x2 y2"
```

The following example adds buffers on net1 using the lib/BUF library cell. Repeater distance is 40 percent of the total route length and a first distance of 20 percent of the total route length is specified.

```
prompt> add_buffer_on_route \\
   -repeater_distance_length_ratio 0.4 \\
   -first_distance_length_ratio 0.2 \\
   net1 -lib_cell lib/BUF
```

The following example adds buffers on net1 using the lib/BUF library cell. A repeater distance of 100 is used. The distance scaling factor for METAL2 is 0.9 and the distance scaling factor for METAL3 is 0.8. The repeat distance is scaled by the route width on each layer.

```
prompt> add_buffer_on_route -repeater_distance 100 \\
   -scaled_by_width -scaled_by_layer { {METAL2 0.9} {METAL3 0.8} } \\
   net1 -lib_cell lib/BUF
```

The following example snaps the new added buffers to the nearest sites.

```
prompt> add_buffer_on_route -location {100 200 METAL3} net1 \\
   -lib_cell lib/BUF -snap_to_sites
```

The following example creates the necessary hierarchical ports after buffer insertion.

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \\
   -lib_cell lib/BUF -punch_port
```

The following example inserts buffers while respecting voltage areas.

Feedback

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \\
   -lib_cell lib/BUF -respect_voltage_areas
```

The following example respects voltage areas and adds buffer in physical-only feedthrough voltage areas.

```
prompt> add_buffer_on_route -repeater_distance 100 h1/net1 \\
   -lib_cell lib/BUF -respect_voltage_areas \\
   -allow_physical_feedthrough_buffer {VA1 VA2}
```

The following example specifies lib cells for voltage areas. Buffers added in va1 uses lib cell BUF1; buffers added in default voltage area uses lib cell buf2; buffers added in all other voltage areas use lib cell BUF0.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \\
   -lib_cell lib/BUF0 \\
   -voltage_area_specific_lib_cells {va1 lib/BUF1 DEFAULT_VA lib/BUF2}
```

The following example adds buffers only within 10 user unit of gas stations for net vdd1. The buffers belong to those gas stations.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \\
   -lib_cell lib/BUF -respect_gas_station vdd1 \\
   -max_distance_route_to_gas_station 10
```

The following example shows enable mv aware features in add_buffer_on_route.

```
prompt> add_buffer_on_route -repeater_distance 100 net1 \\
   -lib_cell lib/BUF \\
   -select_mv_buffers {VA1 lib/BUFS1 lib/BUFD1 VA2 lib/BUFS2 lib/BUFD2}

prompt> add_buffer_on_route -location {35 66 M3} m_1/net1 \\
   -lib_cell lib/BUF -honor_net_hierarchy
```

add_command_hook

Add hook into command execution

Feedback

Syntax

string *add_command_hook* -before *script*

-after *script* -replace *script* [-name *name*] *commandName*

```
string script
string script
string script
string name
string commandName
```

Arguments

`-before script`

Hook runs before command.

`-after script`

Hook runs after command.

`-replace script`

Hook runs in place of command.

`-name name`

Name of hook. If no name is specified a name is automatically generated.

commandName

Command to update.

Description

The *add_command_hook* adds a customization point into the execution of an application command. For example, these hooks can be used to either run a report or gather statistics before and after an application command is run.

Within the body of any hook the get_current_hook_command can be used to query the command and its arguments. For example, a before and after hook may use this information if the hook actions should only happen when specific options are specified. In a replace hook the hook can run the replaced command possibly updating the command options.

This command returns the name of the hook which can be used to remove the hook from the command if desired.

Python Support

When run from a Python, this command expects the supplied script to be a Python script. When the Python hook is run, it is evaluated as if the code is run from within an anonymous function declared at the current scope (global or package). The normal

Feedback

function rules apply. For example, if you want to modify global or package variables, you need to declare them as 'global' within the script.

Examples

Arrange for report timing to be executed every time place_opt_is run.

```
prompt> add_command_hook place_opt -before report_timing
before0
```

Force all report_timing calls to use the -nosplit option.

```
add_command_hook report_timing -replace {eval [get_current_hook_command]
 -nosplit}
```

Python Example

When evaluated from Python the supplied script is Python. A Python equivalent of the previous example, looks like this:

```
def report_timing_hook():
  (command, arg, kwargs) = cmd.get_current_hook_command()
  kwargs['nosplit'] = True
  cmd.result = command(*args, **kwargs)  # Run command, and return the
 result

cmd.add_command_hook(cmd.report_timing, replace='report_timimg_hook()')
```

- get_current_hook_command

---

add_eco_repeater

Adds buffer cells.

Syntax

collection *add_eco_repeater*

```
-cell_name repeater_name
-lib_cell buffer_lib_cell
-input_net_name input_net_name
-output_net_name output_net_name
[-load list_of_pin_or_port_names]
```

Feedback

Data Types

repeater_name	string
buffer_lib_cell	collection
input_net_name	string
output_net_name	string
list_of_pin_or_port_names	list

Arguments

`-cell_name` *repeater_name*

Specifies the name of the repeater to add. It should not be same as the name of an existing cell.

`-lib_cell` *buffer_lib_cell*

Specifies the library cell to be used as buffer. In this case, the object is either a named library cell or a library cell collection. It must be a buffer or inverter.

`-input_net_name` *input_net_name*

Specifies the names of the input net. If it is an existing net, it is connected to the input pin of the repeater; otherwise, a new net is created as this name and connected to the input pin of the repeater. The net cannot be either a PG net or a tie net.

`-output_net_name` *output_net_name*

Specifies the names of the output net. If it is an existing net, it is connected to the output pin of the repeater; otherwise, a new net is created as this name and connected to the output pin of the repeater. The net cannot be either a PG net or a tie net.

`-load` *list_of_pin_or_port_names*

Specifies loads that are driven by the added repeater. Such pins or ports must be connected with the specified and existing input_net or output_net If this option is not specified, all loads of the existing input_net or output_net are driven by the added repeater.

Description

The *add_eco_repeater* command inserts a repeater in an existing net, to buffer all or part of its loads. You must specify such net as either *input_net_name* or *output_net_name*, while the other net must be specified as a new net.

This command support editing a Verilog module in the module aspect, through *edit_module*.

This command checks if the block is editable before adding buffer cells.

Feedback

This command honors the *design.eco_freeze_silicon_mode* application option. When this application option is *true*, the *is_fs_eco_add* attribute of the added buffers added is set to *true*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example specifies the existing net n1 as *input_net_name* and all of its loads are buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name n1 \\
    -output_net_name newNetName -lib_cell INVLVTD0
```

The following example specifies the existing net n1 as *output_net_name* and all of its loads are buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name newNetName \\
    -output_net_name n1 -lib_cell INVLVTD0
```

The following example specifies the existing net n1 as *output_net_name* and only its loads {U1/A U2/A} are buffered, other loads connected with n1 are not be buffered.

```
prompt> add_eco_repeater -cell_name ecoCell -input_net_name newNetName \\
    -output_net_name n1 -lib_cell INVLVTD0 -load {U1/A U2/A}
```

The following example shows that this command also support editing a Verilog module.

```
prompt> edit_module h1m {add_eco_repeater -cell_name ecoCell \\
    -input_net_name newNetName -output_net_name n1 -lib_cell \\
    INVLVTD0 -load {U1/A U2/A} }
```

See Also

- edit_module
- remove_eco_repeater

---

add_feedthrough_buffers

Inserts buffers on all feedthrough nets.

Syntax

status *add_feedthrough_buffers*

```
[-type buffer | inverter]
[-buffer_side input | output | both]
[-user_buffer cell_ref]
```

Feedback

```
[-nets nets]
[-logical]
[-verbose]
```

Data Types

```
cell_ref    string
nets        collection
```

Arguments

`-type buffer | inverter`

Specifies the type of cell, buffer or inverter, to use for isolating feedthroughs. By default, a buffer is used.

`-buffer_side input | output | both`

Specifies what side of the net should the feedthrough buffer be added. Possible values are input, output, or both. By default, the buffer is added on the output side. This option is honored only for physical feedthroughs, not for logical feedthroughs.

`-user_buffer cell_ref`

Specifies the buffer library cell to use for all feedthroughs.

`-nets nets`

Specifies a collection of nets to work on. Only feedthroughs on ports on those nets are isolated.

`-logical`

Inserts logical feedthroughs as well as physical feedthroughs. This option helps to eliminate assign statements in the output Verilog for all nonleaf hierarchical cells.

`-verbose`

Prints additional debugging information to the terminal.

Description

This command identifies all feedthroughs in the design and buffers them according to command options. By default, the command inserts buffers on a feedthrough net near the output port of the feedthrough.

Examples

The following example inserts buffers on all physical feedthroughs, with buffers on both input and output ports, with user buffer type libcell.

Feedback

```
prompt> add_feedthrough_buffers -buffer_side "both" -user_buffer
 "libcell1"
```

The following example inserts buffers on all physical and logical feedthroughs.

```
prompt> add_feedthrough_buffers -logical
```

See Also

- remove_feedthroughs

---

add_group_repeaters

Adds repeater groups for the given group of nets or bundles.

Syntax

collection *add_group_repeaters*

```
-nets collection_of_nets | -bundles collection_of_bundles
[-repeater_distance length]
[-first_distance length |
 -first_distance_of_net_groups first_distance_list]
[-min_distance_repeater_to_load length] [-tolerance length]
| [-relative_distance distance_list]
| [-number_of_repeater_groups number]
| [-location location_list]
| [-cutlines cutline_list]
| [-cutlines_of_net_groups cutline_list]
| [-check_prerequisite]
[-lib_cell repeater_lib_cell]
[-lib_cell_input lib_cell_pin]
[-lib_cell_output lib_cell_pin]
[-net_prefix prefix]
[-cell_prefix prefix]
[-allow_insertion_over_block]
[-horizontal_repeater_spacing spacing]
[-vertical_repeater_spacing spacing]
[-snap_pattern pattern]
[-snapping_row_offset number]
[-snapping_column_offset number]
[-preview]
[-layer_cutting_spacing layer_cutting_spacing_list]
[-layer_cutting_distance distance_list]
[-honor_special_cell collection_of_lib_cells]
[-honor_user_net_grouping_id list_of_group_ids]
[-group_spacing group_spacing_in_um]
[-exclude_pin_port]
[-ignore_layers]
[-max_nets_in_group number]
[-va_aware |
```

Feedback

```
-voltage_area_specific_cells voltage_area_lib_cell_list |
-select_mv_buffers mv_select_lib_cell_list]
```

Data Types

collection_of_nets	collection
collection_of_bundles	collection
length	float
first_distance_list	list
distance_list	list
number	integer
location_list	list
cutline_list	list
repeater_lib_cell	string
lib_cell_pin	string
prefix	string
spacing	integer
pattern	string
layer_cutting_spacing_list	list
collection_of_lib_cells	collection
list_of_group_ids	list
group_spacing_in_um	list
voltage_area_lib_cell_list	list
mv_select_lib_cell_list	list

Arguments

`-nets` *collection_of_nets*

Specifies multiple nets for adding group repeaters. This option is required.

`-bundles` *collection_of_bundles*

Specifies the multiple bundles for adding group repeaters. This option is required.

`-repeater_distance` *length*

Specifies the distance between repeater groups. This option is mutually exclusive with *-relative_distance* option, *number_of_repeater_groups* option, *-location* option, *-cutlines* option, *cutlines_of_net_groups* option, and *check_prerequisite* option.

`-first_distance` *length*

Specifies the distance from drivers to the first group of repeaters. Use with *-repeater_distance* option. This option is mutually exclusive with *-first_distance_of_net_groups* option.

Feedback

`-first_distance_of_net_groups` *`first_distance_list`*

Specifies the first distance for each target net group. This option must be used with *-repeater_distance* option. Specify the option by using the following format:

```
{{group_id1 first_dist1} {group_id2 first_dist2} ...}
```

With this option, the command does net grouping based on existing group IDs on nets and insert repeaters based on different first distance for different net groups. The repeater distance is same for all net groups. The input nets by -nets or -bundles must have net group id by eco_net_group_id and the net group id must be specified in *-first_distance_of_net_groups* option, otherwise, the command errors out. The usage flow is like below.

```
Step1: create_group_repeaters_guidance -nets nets \\
         [-number_of_interleaving_groups $num]
Step2: add_group_repeaters -lib_cell $ref_name -nets $nets \\
         -repeater_distance 200 \\
         -first_distance_of_net_groups {{0 100} {1 200} ...}
```

`-min_distance_repeater_to_load` *`length`*

Specifies the minimum distance from last repeater group to the loads. This is only honored in two-pin nets. Use with *-repeater_distance* option.

`-tolerance` *`length`*

Specifies maximum delta distance over repeater distance. Use with *-repeater_distance* option.

`-relative_distance` *`distance_list`*

Specifies the distances from the drivers to the first group of repeaters, then first group to second group of repeaters, and so on. This option and *-repeater_distance* option are mutually exclusive.

`-number_of_repeater_groups` *`number`*

Specifies the total number of repeater groups to be inserted. If the lib cell is inverting, the specified number must be even. This option can only be used in two-pin nets. This option and *-repeater_distance* option are mutually exclusive.

`-location` *`location_list`*

Specifies the center point coordinates for the locations of repeater group centers. This option and *-repeater_distance* option are mutually exclusive. The format is:

```
{x1 y1 x2 y2 x3 y3 ...}
```

You must specify one location per repeater group when inserting buffers. You must specify two locations per inverter pair when inserting inverters. These locations can be any valid {x_coordinate y_coordinate} pair that is not far away

Feedback

from the placement region of the core area and is relative to the chip origin. These locations must be within a region from the route. Specify the coordinates in user units.

`-cutlines` *`cutline_list`*

Specifies line segments for the locations of repeater group centers. Cutline is a pair of points. It must be orthogonal to the routes. This option and *-repeater_distance* option are mutually exclusive. The format is:

```
{{{x y1} {x y2}} {{x1 y} {x2 y}} ...}
```

You must specify one cutline per repeater group when inserting buffers. You must specify two cutlines per inverter pair when inserting inverters. These cutlines can be any valid pair of points {{x1 y1} {x2 y2}} that is orthogonal to the routes. Specify the coordinates in user units.

Optionally, you can specify metal layer with each cutline in the cutline list.

For example, Single cut line with or without layer name:

```
-cutlines { {x1 y1} {x2 y2} }
-cutlines { {x1 y1} {x2 y2} M3 }
-cutlines { {{x1 y1} {x2 y2} M3} }
```

For example, Multiple cut lines with or without layer names:

```
-cutlines { {{x1 y1} {x2 y2}} {{x3 y3} {x4 y4}} }
-cutlines { {{x1 y1} {x2 y2} M3} {{x3 y3} {x4 y4} M4}}
-cutlines { {{x1 y1} {x2 y2} M3} {{x3 y3} {x4 y4}} }
```

`-cutlines_of_net_groups` *`cutline_list`*

Specifies the cutline list for each target net group. Specify the option by using the following format:

```
{{groupId1 {{x1 y1} {x2 y2}} {{x3 y3} {x4 y4} M3} ...}
 {groupId2 ...} ...}
```

With this option, the command does net grouping based on existing group IDs on nets and insert repeaters based on cutlines for different net groups. The input nets by -nets or -bundles must have net group id by eco_net_group_id and the net group id must be specified in -cutlines_of_net_groups, otherwise, the command errors out. The usage flow is like below.

```
Step1: create_group_repeaters_guidance -nets nets \\
         [-number_of_interleaving_groups $num]
Step2: add_group_repeaters -lib_cell $ref_name -nets $nets \\
         -cutlines_of_net_groups { {0 {{735 200} {735 400} M4}
 {{900 320} {970 320} }} \\
                                   {1 {{835 200} {835 400} M2}
 {{900 420} {970 420} M1}}}
```

Feedback

`-check_prerequisite`

Does a prerequisite check of the design. This is optional. This option and *-repeater_distance* option are mutually exclusive. When the option is specified, only *-nets* or *-bundles* are required. When the option is not specified, one of *-nets* and *-bundles*, and *-lib_cell*, and one of *-repeater_distance*, *-relative_distance*, *-number_of_repeater_groups*, *-location* and *-cutlines* are required.

`-lib_cell` *`repeater_lib_cell`*

Specifies the library cell object to use as a repeater. The object is either a named library cell or a library cell collection.

The library cell must be either buffer or inverter. The command automatically determines the type of the library cell and inserts buffer or inverter pairs on routes based on the type.

`-lib_cell_input` *`lib_pin`*

Specifies the input pin name of the library cell. This is optional.

`-lib_cell_output` *`lib_pin`*

Specifies the output pin name of the library cell. This is optional.

`-net_prefix` *`prefix`*

Specifies the prefix to be used for new nets that are created when buffers are inserted in the netlist. By default, the command uses "eco_net" as the prefix.

`-cell_prefix` *`prefix`*

Specifies the prefix to be used for new buffers that are inserted in the netlist. By default, the command uses "eco_cell" as the prefix. This option cannot be used with the *-user_specified_buffers* option.

`-allow_insertion_over_block`

Specifies if repeater groups can be inserted on top of blocks. This is optional.

`-horizontal_repeater_spacing` *`spacing`*

Specifies the horizontal spacing between two adjacent repeaters in the horizontal direction in terms of number of site width. For example, when -snap_pattern is checkerboard, if the width of repeater is 9 cell site, then the minimum horizontal spacing is 9. If you specify it less than 9, it automatically extends the spacing to 9. In order to make the checkerboard pattern, horizontal spacing should be 9,13,17,21... in this case.

`-vertical_repeater_spacing` *`spacing`*

Specifies the vertical spacing between repeaters in the vertical direction in terms of number of site height. When *-snap_pattern* is checkerboard, specified

Feedback

library cell is single site height, the minimum vertical spacing is 1 site height. In order to make a checkerboard pattern, vertical spacing should be 1,5,9...in this case. When you specify vertical spacing as 4, it automatically rounds to 5. For a double site height library cell, you can specify 2,6,10...to ensure checkerboard pattern.

`-snap_pattern` *`pattern`*

Specifies repeater patterns within a group, support pattern: -checkerboard. If you do not specify *-snap_pattern*, then default snap pattern is checkerboard insertion pattern.

`-snapping_row_offset` *`number`*

Specifies the offset from the first site row. Offset is an integer indicating the number of site rows. This option can be only used when given library cell is multiple site height.

`-snapping_column_offset` *`number`*

Specifies the offset from the first cell site. Offset is an integer indicating the number of cell sites. This option can be only used when given library cell is multiple site height.

`-preview`

Displays repeaters as gui annotation objects.

`-layer_cutting_spacing`

Specifies the layer cutting spacing list, routes on output side of repeaters are right next to repeaters boundary, routes on input side of repeater can be further away from the repeater boundary. Specify the option by using the following format:

```
{{layer1 cutting_spacing_1} {layer2 cutting_spacing_2} ...}
```

`-layer_cutting_distance`

Specifies the layer cutting distance list, you can define input routes and output routes to cell center distances. Specify the option by using the following format:

```
{{layer1 cutting_distance_in_1 cutting_distance_out_1} \\
{layer2 cutting_distance_in_2 cutting_distance_out_2} ...}
```

`-honor_special_cell` *`lib_cell_collection`*

Specifies a collection of library cells that repeaters do not insert overlap with these cells.

Feedback

`-honor_user_net_grouping_id` *`list_of_group_ids`*

Uses existing group id on nets (net attribute eco_net_group_id). You have to specify the descending priorities of net groups for repeater insertion.

`-group_spacing` *`group_spacing_in_um`*

Specifies the maximum spacing between routes to be in a group. The default is twice that of site height. This is optional.

`-exclude_pin_port`

Ignores driver and load pins when grouping nets. With this option, signal direction in a net group might not be the same. This option cannot be used with *-repeater_distance*, *-relative_repeater_distance*, and *-number_of_repeaters* options.

`-ignore_layers`

Ignores routing layers when grouping nets. With this option, nets in the same group might not route on the same layer.

`-max_nets_in_group` *`number`*

Specifies the maximum number of nets in a group. When the number of nets in a group from automatic net grouping exceeds the specified number, the nets are split into separate groups.

`-va_aware`

Inserts repeaters at the specified locations, even if they are physical-only feedthroughs. This option is mutually exclusive with *-voltage_area_specific_lib_cells*, and *-select_mv_buffers* options.

`-voltage_area_specific_lib_cells` *`voltage_area_lib_cell_list`*

Specifies library cell objects to be used in the specified voltage areas. The format is:

```
{{va1 lib_cell1} {va2 lib_cell2} ...}
```

For the default voltage area, specify DEFAULT_VA as the voltage area name. If a buffer is added within a voltage area that is not specified by this option, the lib cell specified by *-lib_cell* is used. This option is mutually exclusive with *-va_aware*, and *-select_mv_buffers* options.

`-select_mv_buffers` *`mv_select_lib_cell_list`*

Specifies single rail and dual rail library cell objects to be used in the specified voltage areas. The format is:

```
{{va1 single_rail_lib_cell1 dual_rail_lib_cell1} \\
{va2 single_rail_lib_cell2 dual_rail_lib_cell2} ...}
```

Feedback

When this option is specified, command enables mv aware features. It selects the mv legal lib cell from the input list to create buffers and update supply net automatically. For the default voltage area, specify DEFAULT_VA as the voltage area name. For the voltage areas not specified by this option, command uses the lib cell specified by *-lib_cell*. This option is mutually exclusive with *-va_aware*, and *-voltage_area_specific_lib_cells* options.

Description

When *-check_prerequisite* is specified, this command does not add any repeaters. Only a prerequisite check of pins, ports, and routes of the input nets are done.

When *-check_prerequisite* is not specified, this command adds repeater groups for the given nets or bundles with distance specified by you between the repeater groups or locations. This command creates the following collections: all newly-added repeaters (*agr_new_repeaters*), all the unrouted nets(*agr_unrouted_nets*) and all the nets that failed to insert buffers(*agr_unbuffered_nets*).

Examples

The following examples show some different usages of command options.

```
prompt> add_group_repeaters -bundle {bundle_1 bundle2} -repeater_distance
 100

prompt> add_group_repeaters -nets pr_nets -relative_distance {70 90 90
 60} \\
  -lib_cell lib/INV0

prompt> add_group_repeaters -nets pr_nets -location {200 2500 300 2500
 400 2500 500 2500} \\
  -lib_cell lib/XOR4 -lib_cell_input "A4" -lib_cell_output "Z"

prompt> add_group_repeaters -bundles [get_bundles] \\
-lib_cell lib/BUF1 -number_of_repeater_groups 20

prompt> add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP \\
-cutlines { {2632 1288} {2632 856} }

prompt> add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP \\
-cutlines {{2632 1288} {2632 856}} -smart_net_grouping

prompt> add_group_repeaters -nets pr_nets -lib_cell BUFFD4BWP \\
-cutlines {{2632 1288} {2632 856}} -honor_user_net_grouping_id {3 2 1 6 5
 4 0}

prompt> add_group_repeaters -nets pr_nets -check_prerequisite
prompt> add_group_repeaters -bundles {bundle_1 bundle_2}
 -check_prerequisite
```

Feedback

```
prompt> add_group_repeaters -lib_cell $ref_name -nets nets
 -repeater_distance 200 \\
        -first_distance_of_net_groups {{0 100} {1 200} ...}

prompt> add_group_repeaters -lib_cell $ref_name -nets $nets \\
        -cutlines_of_net_groups { {0 {{735 200} {735 400} M4} {{900 320}
 {970 320} }} \\
                                  {1 {{835 200} {835 400} M2} {{900 420}
 {970 420} M1}} \\
                                  {2 {{835 200} {835 400}} {{900 420}
 {970 420}}}}
```

---

add_lib_cells_to_family

Add a set of library cells to an existing user-defined family.

Syntax

status *add_lib_cells_to_family*

```
-name family_name_string
-lib_cell lib_cell_list
```

Data Types

```
family_name_string  string
lib_cell_list       list-of-lib_cell-objects
```

Arguments

`-name` *family_name_string*

The name of the existing user-defined family, where the library cells will be added to.

`-lib_cell` *lib_cell_list*

The list of library cells to be added to the existing user-defined family.

Description

Add library cells to an existing user-defined family.

Here is an example:

```
add_lib_cells_to_family -name inv -lib_cell [get_lib_cell {*/INVD1*
 */INVD2 libA/INVD6 libB/INVD8}]
```

See Also

- define_lib_cell_family
- remove_lib_cells_from_family
- report_lib_cell_families

---

add_macro_to_group

Add macro to macro group.

Syntax

```
status add_macro_to_group
-group macro_group
-macros list_of_macros
```

Data Types

list_of_macros collection of macros

Arguments

`-group macro_group`

Specifies macro group.

`-macros list_of_macros`

Specifies macros.

Description

This command add macros to the macro group. If the macro belongs to another macro group before the command, it will be removed from that macro group and added to the new macro group. If the macro group contains macros before the command, the added macros and existing macros must belong to the same placeable area, i.e, movebound, voltage area, and block. If a macro belongs to a macro array, the array will be added to the macro group.

Examples

The following command add macros M1, M2 to macro group groups.

```
prompt> add_macro_to_groups -group group1 -macros {M1 M2}
```

Feedback

The following command add macro M1 to macro group group1. M1 belongs to a macro array array1. As the result, all macros of the array will be added to the macro group.

```
prompt> create_macro_array -num_rows 2 -num_cols 2 {M1 M2 M3 M4} \\
  -name my_edit_group
prompt> add_macro_to_group -group group1 -macros M1
```

See Also

- create_macro_groups
- remove_macros_from_group

---

add_parameter

Defines parameters that can be overridden by apply_power_model.

Syntax

string *add_parameter*

```
parameter_name
-default default_value
[-type type_name]
[-description description_text]
```

Data Types

```
parameter_name      string
default_value       string
type_name           buildtime, runtime, or rate
description_text    string
```

Arguments

parameter_name

Specifies the name of the parameter to be defined inside a power model.

-default *default_value*

Specifies the default of the parameter if there is no parameter mapping specified in the *apply_power_model* command.

-type *type_name*

When -type option is specified, the parameter defined is used for system-level IP power model. The parameter scope is within the power model only and power models and power functions cannot access parameters that are defined outside of the power model in which they are used.

Feedback

Three types of parameters 3 can be defined as follows:

```
1. Build time - for parameters that remain unchanged during
 runtime
2. Run time - for parameters that can change during runtime
3. Rate - for parameters that represent rate-based quantities
 that
can change during runtime
```

`-description` *`description text`*

Text description of the parameter.

Description

The *add_parameter* command is used to define parameters for use within a power model. A parameter can be used just like a regular Tcl variable by prepending the parameter name with the $ keyword.

This command can only be defined within the *define_power_model* command and applied to a macro instance through the *apply_power_model* command. It is an error if this command is executed through the *load_upf* command.

The *-parameters* option of the *apply_power_model* command can change the value of a parameter during application of the power model on a macro instance. If the parameter is not found in the *-parameter* option,default value specified in *add_parameter* is used.

A power model provides a self-contained environment for variables. Parameters defined outside a power model are not visible inside the power model. Parameters defined within a power model are only visible inside the power model.

Examples

The following example defines a power model with three parameters: PD_NAME, process, and cache_miss.

```
define_power_model MODEL -for {lib_cell}
{add_parameter PD_NAME -default "PD" -description "power domain in model"
  add_parameter process -type buildtime -default 1.0
  add_parameter cache_miss -type rate -default 0.02
  create_supply_net VDD
  create_supply_net VSS
  create_supply_set SS -function {power VDD} -function {ground VSS}
  create_power_domain $PD_NAME -supply {primary SS} -include_scope
}

apply_power_model MODEL -parameters {PD_NAME pd_macro}
```

Feedback

---

add_pins_to_virtual_connection

Connects pins or ports to the virtual connection.

Syntax

status *add_pins_to_virtual_connection*

```
-object virtual_connection
-pins pin_port_list
```

Data Types

```
virtual_connection        collection
pin_port_list             collection
```

Arguments

`-object virtual_connection`

Specifies one virtual connection.

`-pins pin_port_list`

Specifies a list of pins and ports to be connected to the virtual connection. The command errors out if any pin is connected to the existing virtual connection.

Description

This command connects pins to the specified virtual connection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples connect pins to the virtual connection.

```
prompt> add_pins_to_virtual_connection \\
   -object [get_virtual_connections -name SNPS_vc_0] \\
   -pins {lh1/ff3/Y U2/A U3/A MemData[0]}
```

Feedback

```
prompt> add_pins_to_virtual_connection \\
   -object [get_virtual_connections -name SNPS_vc_0] \\
   -pins [get_pins {U2/A U3/A}]

prompt> add_pins_to_virtual_connection \\
   -object [get_virtual_connections -name SNPS_vc_0] \\
   -pins [get_ports MemData[0]]
```

- remove_virtual_connections
- set_attribute

---

add_port_protection_diodes

Adds diodes around the specified ports to protect them. One diode is added to each specified port.

Syntax

status *add_port_protection_diodes*

```
[-prefix name]
[-ignore_dont_touch]
-diode_lib_cell lib_cell
-port ports
```

Data Types

```
name          string
lib_cell      collection
ports         collection
```

Arguments

`-prefix name`

Specifies the prefix used to identify the newly added diode cells. By default, no prefix is used and the tool assigns a cell name.

Feedback

`-ignore_dont_touch`

Specifies that port protection diodes can be added to nets with the dont_touch attribute.

By default, port protection diodes are not inserted on nets that have the dont_touch attribute.

`-diode_lib_cell` *`lib_cell`*

Specifies the name of the library reference cell used for the new diodes. You can specify only a single library cell.

This is a required option.

`-port` *`ports`*

Specifies the ports to which to connect protection diodes.

This is a required option.

Description

The *add_port_protection_diodes* command performs the following tasks:

1. Creates the new diodes and adds them into the netlist.
2. Connects the new diodes to the specified ports.
3. Legalizes the diodes.
4. Marks the diodes as fixed.

Use this command in the preroute stage to prevent antenna violations.

Note that if this command succeeds, all of the inserted diodes are located at legal locations and marked as fixed. However, this does not necessarily mean that other movable standard cells are in legal locations. It is possible that some movable standard cells overlap with the inserted diodes. To legalize these standard cells, run the *place_opt*, *clock_opt* command or the *legalize_placement* command.

Multicorner-Multimode Support

This command uses information from all active scenarios.

Examples

The following example runs the *add_port_protection_diodes* command.

```
prompt> add_port_protection_diodes -prefix MY_DIODE \\
-diode_lib_cell [get_lib_cell XXX] -port [all_inputs]
```

Feedback

See Also

- report_port_protection_diodes
- remove_cells
- legalize_placement

---

add_port_state

Defines the names and voltages of the possible states of a supply port for a UPF power state table.

Syntax

string *add_port_state*

```
supply_port_name
-state {state_name state_value}
```

Data Types

```
supply_port_name     string
state_name           string
state_value          string
```

Arguments

supply_port_name

Specifies the name of the supply port. Hierarchical names are allowed. Use only supply port names previously listed in the *create_pst* command.

`-state {state_name state_value}`

Specifies the name and value of a state of the supply port. You can repeat this option in the command to define multiple supply states.

The supply state value can be specified as one of the following:

- A single floating-point number that represents the nominal voltage for the named state:

  ```
  -state {sLO 0.88}
  ```

- Three floating-point numbers that represent the minimum, nominal, and maximum voltages of the named state:

  ```
  -state {sLO 0.88 0.90 0.92}
  ```

- The keyword *off*, which represents the inactive state:

  ```
  -state {PDOWN off}
  ```

Feedback

Description

The *add_port_state* command adds state information to a supply port for a UPF power state table. The command specifies the name of the supply port and the possible states of the port. Each state is specified as a state name and the voltage level for that state.

State name must meet UPF naming convention. Otherwise tool issues an error.

You can specify the voltage level as a single nominal value, a set of three values (minimum, nominal, and maximum), or the keyword *off* to indicate the off state. The first state specified is the default state.

A port might be in any of the defined states and can take any voltage within a defined range, so a tool cannot determine the voltage to use from the power state table alone. In most tools, use the *set_voltage* command (a non UPF command) to specify the operating voltage.

Use the *create_pst* command first, then the *add_port_state* command to specify the names and voltages of the possible states for each supply port, and finally the *add_pst_state* command to specify the allowed combinations of supply states. Here is an example:

```
# Create power state table, specify supply ports for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_port_state PN1     -state {sLO 0.88}
add_port_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_port_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the *create_pst* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example shows the states and voltages of a supply port named VN1:

```
prompt> add_port_state VN1 \\
        -state {active_state 0.88 0.90 0.92} \\
        -state {off_state off}
```

- report_pst

---

add_power_state

Adds power state information to a supply set.

Syntax

status *add_power_state*

```
[-supply] | [-group] | [-domain] object_name
-state state_name
[-supply_expr supply_expression]
[-logic_expr  logic_expression]
[-simstate    simstate]
[-illegal]
[-update]
```

Data Types

```
object_name          string
state_name           string
supply_expression    string
logic_expression     string
simstate             string
```

Arguments

`-supply` *object_name*

Specifies the name of the supply set. This option is mutually exclusive with *-group* option and *-domain* option. The name should be a simple, non-hierarchical name.

Feedback

`-group` *object_name*

Specifies the name of the group set. This option is mutually exclusive with *-supply* option and *-domain* option. The name should be a simple, non-hierarchical name.

`-domain` *object_name*

Specifies the name of the domain set. This option is mutually exclusive with *-supply* option and *-group* option. The name should be a simple, non-hierarchical name.

`-state` *state_name*

Specifies the name of the state of the supply set. The name should be a simple, non-hierarchical name.

`-supply_expr` *supply_expression*

- Used without *-supply* option. Specifies the net and netstate. Use the following syntax for *-supply_expr* option when specified without *-supply* option.

  ```
  net == netstate
  ```

- Used with *-supply* option. Specifies the net and netstate. Use the following syntax for *-supply_expr* option when specified with *-supply* option.

  ```
  net == netstate && net == netstate
  net == netstate || net == netstate
  (net == netstate && net == netstate) || \\
  (net == netstate && net == netstate)
  ```

  The *-net* can be power or ground, and the *-netstate* syntax must be one of the following:

  ```
  status in V2.0 syntax without -supply option and single ==
   state
  `{status}
  `{status, nom}
  `{status, min, max}
  `{status, min, nom, max}

  status in V3.0 syntax with -supply option or multiple == state
   with &&/|| \\
  supported
  {status}
  {status nom}
  {status min max}
  {status min nom max}
  ```

- *status* can be OFF or FULL_ON

Feedback

- *min*, *nom*, and *max* are floating-point numbers representing the minimum, nominal, and maximum voltages of the specified state, respectively.
- If the *status* is FULL_ON, at least one voltage must be defined. You can specify one or three voltage values. If three values are specified, they should be in increasing order.

`-logic_expr` *`logic_expression`*

- Used without *-group* and *-domain* options Specifies a SystemVerilog Boolean expression in terms of logic nets and supply nets when The *-logic_expr* option does not affect implementation and is intended to be used by simulation tools, to read and write transparently.
- Used with *-group* and *-domain* options Specifies expression in terms of group or domain state or supply set state. Use the following syntax for *-logic_expr* option when specified along with *-group* and *-domain* options.

  ```
  supplySet/group/PST/domain == state
   && supplySet/group/PST/domain ==
  state
  ```

  Note that || operator is not supported for supply set states in *-logic_expr*.

`-simstate {`*`simstate`*`}`

Specifies a simstate for the power states associated with a supply set, valid values are NORMAL, CORRUPT_ON_ACTIVITY, CORRUPT, NOT_NORMAL, CORRUPT_STATE_ON_CHANGE, CORRUPT_STATE_ON_ACTIVITY, and CORRUPT_ON_CHANGE. The *-simstate* option does not affect implementation and is intended to be used by simulation, so the tool reads and writes the information specified with this option transparently.

`-illegal`

Defines the power state as illegal, if specified. If not specified the state is legal state by default.

`-update`

Indicates this command provides additional information for a previous command with the same object_name and executed in the same scope.

Description

This command defines one or more power states of an object. Power states might be defined for a supply set, a power domain, a group.

This command issues an error, if the *object_name* does not already exist as supply set or power state group or power domain.

Feedback

For supply set state, the *-update* option is supported for new state definition but it is optional.

```
For example
prompt> add_power_state SS1 -state SS1_state1 ...
```

To add another SS1_state2, there are three ways to do it:

```
prompt> add_power_state SS1 -state SS1_state1 ... -state SS1_state2 ...
prompt> add_power_state SS1 -state SS1_state2 ...
prompt> add_power_state SS1 -state SS1_state2 ... -update
```

For group state, the *-update* option is mandatory for new state definition in this release.

```
prompt> add_power_state -group GroupA -state A_state1 ...
```

To add another A_state2, there are two ways to do it:

```
prompt> add_power_state -group GroupA -state A_state1 ... -state
 A_state2 ...
prompt> add_power_state -group GroupA -state SS1_state2 ... -update
```

The following example gives an error when the *-update* option is not used:

```
prompt> add_power_state -group GroupA -state SS1_state2 ...
```

For supply set state, the *-update* option is supported for sub state conjunctions :

```
For example
prompt> add_power_state SS1
        -state HPg {-supply_expr {(power == {OFF}) && (ground =={FULL_ON
 0})}}
```

Or use the *-update* option:

```
prompt> add_power_state SS1
        -state HPg {-supply_expr {(power == {OFF})}
prompt> add_power_state SS1
        -state HPg {-supply_expr {(ground =={FULL_ON 0})}} -update
```

The following example gives an Error for duplicated definition of state HPg when the *-update* option is not used.

```
prompt> add_power_state SS1
        -state HPg {-supply_expr {(ground =={FULL_ON 0})}}
```

For group state, *-update* is also supported for sub state conjunctions:

```
For example
prompt> add_power_state -group group_A
        -state lo2 {-logic_expr {SS1 == HPg && SS2 == HVp}
```

Feedback

Or use the *-update* option as shown here:

```
prompt> add_power_state group1
         -state lo2 {-logic_expr {SS1 == Hpg}}
prompt> add_power_state group1 \\
         -state lo2 {-logic_expr {SS2 == HVp}} -update
```

You can even create an empty power state first, then update it later:

```
prompt>add_power_state SS1 -state ON {}
prompt>add_power_state SS1 ON {-supply_expr {power == FULL_ON}} -update
```

The domain state has same usage as group/supply set, with -update option.

```
prompt> add_power_state domain1
          -state hi_state {-logic_expr {SS1 == HPg && primary == HVp}}
prompt> add_power_state domain1
          -state off_state {-logic_expr {SS1 == HPg && primary == OFF}}
 -update
prompt> add_power_state group1 -state hi {-logic_expr {domain1 ==
 hi_state}}
```

Examples

The following example shows the states and voltages of a supply set, SS1:

```
prompt> add_power_state SS1
        -state HVp {-supply_expr {power == `{FULL_ON, 0.88, 0.90, 0.92}}}

prompt> add_power_state SS1
        -state HPg {-supply_expr {ground == `{OFF}}}

prompt> add_power_state SS1 -supply
        -state HPg {-supply_expr {(power == {OFF}) && (ground =={FULL_ON
 0})}}

prompt> add_power_state -group group_A
        -state lo2 {-logic_expr {SS1 == HPg && SS1 == HVp}
```

The following example uses || operator in *-supply_expr*:

```
prompt> add_power_state SS1
        -state ON {-supply_expr {ground == {FULL_ON 0.0}}}

prompt> add_power_state SS1 -update
        -state ON {-supply_expr {power == {FULL_ON 0.7} || power ==
 {FULL_ON 1.2}}}
```

---

add_powertap_shield_association

Associates powertap to shielding shape.

Syntax

status *add_powertap_shield_association*

```
-shape  shielding shape
-net clock net
-cell power tap
```

Data Types

```
shape       object
net         object
cell        object
```

Arguments

`-shape shield_shape`

Specifies a shielding shape to add to shield association.

`-net clock_net`

Specifies a shielded net for association.

`-cell power_tap_cell`

Specifies a power tap cell to add to shield association.

Description

The *add_powertap_shield_association* command associates the specified shielding shape to the specified power tap cell.

Examples

The following example adds shielding shape 'shape1' and shielded net 'net1' to power tap cell 'ptap1' association.

Feedback

```
prompt> add_powertap_shield_association -shape shape1 -net net1 -cell
 ptap1
1
```

See Also

- report_power_taps

---

add_pst_state

Defines the states of each of the supply ports or nets for one possible state of the design for a UPF power state table.

Syntax

status *add_pst_state*

```
state_name
-pst table_name
-state supply_states
```

Data Types

state_name	string
table_name	string
supply_states	list

Arguments

state_name

Specifies a name for the power state being defined in the command.

-pst *table_name*

Specifies the name of the power state table previously defined by the *create_pst* command. The power state being defined is added to this power state table.

-state *supply_states*

Lists the supply state names in the order corresponding to the *-supplies* option listing in the *create_pst* command. For the power state being defined, the listed supply states are active for the respective supplies. The supply state names in the list must be defined by previous *add_port_state* commands.

Description

The *add_pst_state* command defines the states of each of the supply ports or supply nets for one possible power state configuration of the design for a UPF power state table.

The command specifies a name for the power state, the name of the power state table previously created by the *create_pst* command, and the states of the supply ports in the

Feedback

same order listed in the *create_pst* command. The voltages corresponding to these supply states are defined by the *add_pst_state* command.

The following script demonstrates the power state definition flow:

```
# Create power state table, specify supply ports for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_port_state PN1     -state {sLO 0.88}
add_port_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_port_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the *create_pst* command.

For a group of supply ports and supply nets directly connected together, the allowable supply states are derived from the shared pool of supply states commonly owned by the members of the group.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following script specifies four allowed combinations of supply states for the power state table named MyPST:

```
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
add_pst_state S4 -pst MyPST -state {sHI sLO PDOWN}
```

See Also

- add_port_state

Feedback

add_redundant_vias

Replaces single-cut vias with multiple-cut via arrays. It can also replace a single-cut via with another single-cut via that has a different contact code.

Syntax

status *add_redundant_vias*

```
[-effort low | medium | high]
[-list_only true | false]
[-timing_preserve_nets collection_of_nets]
[-timing_preserve_setup_slack_threshold slack_value]
[-timing_preserve_hold_slack_threshold slack_value]
[-nets collection_of_nets]
```

Data Types

collection_of_nets	collection
slack_value	float

Arguments

`-effort low | medium | high`

Specifies the effort used to perform redundant via insertion.

The default is medium.

`-list_only true | false`

Controls whether the tool performs redundant via insertion or lists the default via mappings to be used for redundant via insertion.

By default (*false*), the tool performs redundant via insertion.

`-timing_preserve_nets` *collection_of_nets*

Specifies the nets to preserve timing on.

If you specify this option, the command considers the specified nets as timing critical and skips redundant via insertion on them.

`-timing_preserve_setup_slack_threshold` *slack_value*

Specifies the setup slack threshold for timing critical nets. The unit of the threshold is in library units.

If you specify this option, the command skips redundant via insertion on all nets with a worst setup slack less than or equal to this value.

Feedback

`-timing_preserve_hold_slack_threshold` *`slack_value`*

Specifies the hold slack threshold for timing critical nets. The unit of the threshold is in library units.

If you specify this option, the command skips redundant via insertion on all nets with a worst hold slack less than or equal to this value.

`-nets` *`collection_of_nets`*

Specifies the nets on which redundant via insertion has to be performed.

By default, redundant via insertion is performed on all nets.

Description

This command replaces one set of vias in the design with another set. By default, all single-cut vias are replaced with 2-cut via arrays. You can change the behavior by using the *add_via_mapping* command to specify the exact via mapping to be used by this command. From a netlist connectivity point of view, using a single-cut via is no different from using a multiple-cut via array, so additional via cuts in a multiple-cut via array are regarded as redundant vias from this point of view. However, redundant vias can increase yield during manufacturing and are an important design-for-manufacturing (DFM) feature.

The command tries to replace vias when the new via or via array does not introduce any design rule violations. However, sometimes new violations are introduced by accident and the command cleans them up later by performing search and repair.

Redundant via insertion runtime is not expected to be more than detail routing runtime but might be similar in cases where a via mapping aims to replace nearly every default via in a block.

Some general guidelines on redundant via insertion (RVI) runtime:

a) RVI via swapping runtime is usually less than total route_detail runtime but more than check_routes. b) RVI via swapping processes the whole design and can perform localized DRC checking around each via. The runtime might be roughly similar to iteration 0 of detail routing. c) Runtime increases if each via has a large number of weight groups defined, and many of the higher weight groups do not have high conversion rates. This indicates runtime is spent attempting but failing to swap for various weight classes before succeeding. d) RVI DRC fixing might have higher runtimes if the design has many DRCs going into RVI, or if RVI via swapping is creating many DRCs.

Examples

The following example replaces all single cut vias by 2-cut via arrays.

```
prompt> add_redundant_vias
```

The following example replaces single-cut vias named VIA23 with 1x3 via arrays named VIA23 and single-cut vias named VIA34 with 5x1 via arrays named VIA34.

Feedback

```
prompt> add_via_mapping \\
   -from {VIA23 1x1} -to {VIA23 1x3}
prompt> add_via_mapping \\
   -from {VIA34 1x1} -to {VIA34 5x1}
prompt> add_redundant_vias
```

The following example replaces single-cut vias named VIA23 with 1x2 via arrays named VIA23 on the net named net1.

```
prompt> add_via_mapping \\
   -from {VIA23 1x1} -to {VIA23 1x2}
prompt> add_redundant_vias -nets net1
```

See Also

- add_via_mapping

---

add_shield_association

Associates shielding shapes and vias to shielded nets.

Syntax

status *add_shield_association*

```
-objects shape_and_via_list
-nets net_list
```

Data Types

```
shape_and_via_list      collection
net_list                collection
```

Arguments

`-objects` *shape_and_via_list*

Specifies a list of shielding shapes and vias to add to shield association.

`-nets` *net_list*

Specifies a list of shielded nets to add to shield association.

Description

The *add_shield_association* command associates the specified shielding shapes and vias to the shielded nets.

Examples

The following example adds shielding shape 'shape1' and shielded net 'net1' to shield association.

Feedback

```
prompt> add_shield_association -objects shape1 -nets net1
1
```

The following example adds shielding via 'via1' and shielded net 'net1' to shield association.

```
prompt> add_shield_association -objects via1 -nets net1
1
```

See Also

- remove_shield_association

---

add_spare_cells

Inserts spare cells into the current design.

Syntax

status *add_spare_cells*

```
-cell_name name
-lib_cell reference [-num_instances number]
| -num_cells cell_ref
[-hier_cell hierarchy_name]
|[-boundary boundary_spec]
|[-voltage_areas voltage_area_list]
[-ignore_blockage_types blockage_type_list]
[-density_aware_ratio percentage] | [-random_distribution]
[-input_pin_connect_type tie_low | tie_high | open]
[-repetitive_window {width height}]
```

Data Types

name	string
reference	collection
number	integer
cell_ref	string
hierarchy_name	collection
boundary_spec	list
voltage_area_list	list
blockage_type_list	list
percentage	integer

Arguments

`-cell_name` *name*

Specifies the name prefix for the spare cells. An integer suffix is automatically appended to the name prefix for each instance. When a name is generated for a

Feedback

spare cell and the name already exists, the tool automatically assigns a unique name for the spare cell.

`-lib_cell` *reference*

Specifies the library cells to insert as spare cells. The input can be names or collections. Use this option together with the *-num_instances* option. This option is mutually exclusive with the *-num_cells* option. This is a required option.

`-num_instances` *number*

Specifies the number of instances of each library cell to add as spare cells. Use this option together with the *-lib_cell* option. This option is mutually exclusive with the *-num_cells* option.

`-num_cells` *cell_ref*

Specifies library cell names and the number of instances to insert for each unique library cell. The valid format is *ref1 num1 ref2 num2 ...*. This option is mutually exclusive with the *-lib_cell* and *-num_instances* options.

`-hier_cell` *hierarchy_name*

Specifies the hierarchy in which to insert the spare cells. The *-hier_cell*, *-boundary* and *-voltage_areas* options are mutually exclusive.

`-boundary` *boundary_spec*

Specifies the boundary of the spare cells. You can use the following methods to specify the boundary:

\ (bu Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

`{{llx lly} {urx ury}}`

\ (bu Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

`{{x1 y1} {x2 y2} ... {xn yn}}`

Only one rectangle or rectilinear polygon is allowed for this option. When specifying this option, new spare cells are inserted inside voltage areas within the specified boundary. The *-boundary* option is mutually exclusive with *-hier_cell*, and *-voltage_areas* options.

`-voltage_areas` *voltage_area_list*

Specifies the voltage areas in which the spares cells are added. The new spare cells are added to these specified voltage areas. The *-hier_cell*, *-boundary* and *-voltage_areas* options are mutually exclusive.

Feedback

`-ignore_blockage_types` *`blockage_type_list`*

Specifies a list of blockage types. The command allows spare cells to be added inside the blockage if blockage type is specified by the option. The command supports all blockage types same as *create_placement_blockage*, but does not honor any placement constraint that the blockage has. If the option is not used, the spare cells cannot be added inside any placement blockage.

`-density_aware_ratio` *`percentage`*

Specifies the percentage of spare cells to be added with density aware. This option allows you to control the percentage of density aware for adding the spare cells. The percentage means the percentage of spare cells are added considering density of existing cells, and the rest is added evenly. The two spreading ways are both blockage aware. This option and *-random_distribution* option are mutually exclusive.

- The default percentage is 100, that means all new spare cells are added with considering cell density;
- 20 means 20percent spare cells are added based on cell density and 80percent spare cells are added evenly across the design;
- 0 means all new spare cells are added evenly without considering cell density.

`-random_distribution`

Places all newly added spare cells randomly. The *-random_distribution* and *-density_aware_ratio* options are mutually exclusive. When the option is used, the tool ignores the current cell density and spare cells are placed with random distribution.

`-input_pin_connect_type tie_low | tie_high | open`

Specifies the connection type of input pins of new spare cells. The valid values are *tie_low*, *tie_high* and *open*.

- *tie_low*: input pins are connected to tie low net.
- *tie_high*: input pins are connected to tie high net.
- *open*: input pins are kept open.

If this option is not specified, the default is *tie_low*.

`-repetitive_window` *`{width height}`*

Adds and places spare cells through repetitive windows. The *width* and *height* are distance with micron unit. When this option is specified, spare cells with the specified number and types are added to each window. And the window applies repetitively starting from the low-left of the placement area. The option *-lib_cell*

Feedback

with *-num_instances* or option *-num_cells* can be used to specify the number and types of spare cells to be added within each window. The specified number is considered the number in each window. For windows that cut by blockage or other voltage areas and windows

For windows whose placeable area is not the same as window size, the cell number is calculated on the area ratio.

- Windows that cut by blockages or other voltage areas.
- Windows that near the boundary edge when the boundary size is not integral multiple of window size.

Description

This command adds a specified number of instances of the library cell as spare cells in a design. It adds the spare cells to the logical netlist and places them in corresponding physical regions as evenly as possible, and avoids all placement blockages.

Specifying more than one library cell allows you to place the instances of different library cells evenly throughout the regions. The library cell must exist in your link libraries.

The *-lib_cell* and *-num_instances* options are used together to insert spare cells with same number of instances for different library cells. To add spare cells with a different number of instances from different library cells, use the *-num_cells* option. You must use one of the *-lib_cell* and *-num_cells* options to specify library cells. The *-num_cells* option is mutually exclusive with the *-lib_cell* and *-num_instances* options.

This command provides three options to distribute the spare cells in different ways:

- *-hier_cell* : Spare cells are placed around the existing placed cells of the specified hierarchy. And these spare cells are also placed inside the regions of the voltage area of the specified hierarchy.
- *-boundary* : Spare cells are added to the voltage areas evenly within the specified boundary. These new cells are also added to the corresponding hierarchies.
- *-voltage_areas* : Spare cells are added to the specified voltage areas evenly. These new cells are also added to corresponding hierarchies.
- If none of these three options is specified, the default behavior is to distribute new spare cells to all voltage areas including the default voltage area for the design.

The *-hier_cell*, *-boundary* and *-voltage_areas* options are mutually exclusive.

The new spare cells are not legalized. You can use *place_eco_cells -legalize_only* or *legalize_placement* to legalize these cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example adds 20 instances of a library cell *and2* with the prefix *SpareCell* to the current design.

```
prompt> add_spare_cells -cell_name SpareCell -lib_cell and2
 -num_instances 20
```

The following example adds 15 instances of library cells *and2* and *nor2* with the prefix *SpareCell* in the hierarchical cell *I_SUB*.

```
prompt> add_spare_cells -cell_name SpareCell \\
   -lib_cell {and2 nor2} -num_instances 15 -hier_cell I_SUB
```

The following example inserts 10 instances of library cell *and1* and 5 instances of library cell *nor1* with the prefix *SpareCell* in the boundary.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell  -boundary {{5.04 2.52} {120.06 80.4}}
```

The following example inserts 10 instances of library cell *and1* and 5 instances of library cell *nor1* with the prefix *SpareCell* in the specified voltage areas.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -voltage_areas pd2
```

The following example uses the *-ignore_blockage_types* option to allow spare cells to be added inside the blockage with user-specified type.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -ignore_blockage_types {soft partial}
```

The following example uses the *-density_aware_ratio* option to allow you to control the percentage of spare cells to be added with density aware.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -voltage_areas pd2 -density_aware_ratio 100
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -voltage_areas pd2 -density_aware_ratio 80
```

The following example uses the *-input_pin_connect_type* option to control the connection type of the input pins of the new spare cells.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -input_pin_connect_type tie_high
```

The following example uses the *-repetitive_window* option to add spare cells by repetitive window.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -repetitive_window {20 20}
```

Feedback

The following example uses the *-random_distribution* option.

```
prompt> add_spare_cells -num_cells {and1 10 nor1 5} \\
   -cell_name SpareCell -random_distribution
```

---

add_state_transition

Defines the named state transitions between power states of an object.

Syntax

status *add_state_transition*

```
[-supply] | [-group] | [-domain] object_name
-transition transition_name
[-from  from_list -to to_list]
[-paired from_state to_state]
[-through through_list]
[-legal] | [-illegal]
[-update]
[-complete]
```

Data Types

```
object_name       string
transition_name   string
from_list         list
to_list           list
from_state        string
to_state          string
through_list      list
```

Arguments

`-supply` *object_name*

Specifies the name of the supply set. This option is mutually exclusive with *-group* option and *-domain* option. The name should be a simple, non-hierarchical name.

Feedback

`-group` *`object_name`*

Specifies the name of the group set. This option is mutually exclusive with *-supply* option and *-domain* option. The name should be a simple, non-hierarchical name.

`-domain` *`object_name`*

Specifies the name of the domain set. This option is mutually exclusive with *-supply* option and *-group* option. The name should be a simple, non-hierarchical name.

`-transition` *`transition_name`*

Specifies the simple name of transition.

`-from` *`from_list`*

Specifies an unordered list of power state names active before a state transition. Empty list expands to all named power states for the specified object.

`-to` *`to_list`*

Specifies an unordered list of power state names active after a state transition. Empty list expands to all named power states for the specified object.

`-paired {`*`from_state to_state`*`}`

Specifies a list of from-state name and to-state name pairs.

`-through` *`through_list`*

Specifies the list of intermediate states. This option is only applicable when *-from* or *-to* options are specified. The effective transition sequence is *-from*, *-through*, *-to*.

`-legal`

Specifies the legality of the transition being defined as legal. This option is mutually exclusive with *-illegal* option. The default is *-legal*.

`-illegal`

Specifies the legality of the transition being defined as illegal. This option is mutually exclusive with *-legal* option.

`-update`

Indicates this command provides additional information for a previous command with the same object_name and executed in the same scope.

`-complete`

Any new transitions defined after the command with *-complete*, results in an error.

Feedback

Description

The *add_state_transition* command defines named state transitions between power states of an object.

This is a new command added in UPF 3.0, it replaces the describe_state_transition.

Examples

The following example shows how to add state transitions:

```
prompt> add_state_transition -domain PDA
    -transition {turn_on -from OFF_MODE -to NORMAL_MODE}
    -transition {suspend -from NORMAL_MODE -to SLEEP_MODE}
    -transition {resume -from SLEEP_MODE -to NORMAL_MODE}
    -transition {turn_off -from NORMAL_MODE -to OFF_MODE}
prompt> add_state_transition -domain PDA -update
    -transition {error1 -from OFF_MODE -to SLEEP_MODE -illegal}
```

See Also

- add_power_state
- describe_state_transition

---

add_supply_state

Defines the names and voltages of the possible states of a supply object for a UPF power state table.

Syntax

string *add_supply_state*

```
supply_name
-state {state_name state_value}
```

Data Types

```
supply_name          string
state_name           string
state_value          string
```

Arguments

supply_name

Specifies the name of the supply port, supply net or supply set function. Hierarchical names are allowed.

Feedback

`-state {state_name state_value}`

Specifies the name and value of a state of the supply. You can repeat this option in the command to define multiple supply states.

The supply state value can be specified as one of the following:

- A single floating-point number that represents the nominal voltage for the named state:

  ```
  -state {sLO 0.88}
  ```

- The keyword *off*, which represents the inactive state:

  ```
  -state {PDOWN off}
  ```

Description

The *add_supply_state* command adds state information to a supply object for a UPF power state table. The command specifies the name of the supply object and the possible states of the object. Each state is specified as a state name and the voltage level for that state.

You can specify the voltage level as a single nominal value, or the keyword *off* to indicate the off state. The first state specified is the default state.

A supply object might be in any of the defined states and can take any voltage within a defined range, so a tool cannot determine the voltage to use from the power state table alone. In most tools, use the *set_voltage* command (a non UPF command) to specify the operating voltage.

Use the *create_pst* command first, then the *add_supply_state* command to specify the names and voltages of the possible states for each supply, and finally the *add_pst_state* command to specify the allowed combinations of supply states. Here is an example:

```
# Create power state table, specify supply ports or nets for table
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_supply_state PN1     -state {sLO 0.88}
add_supply_state PN2     -state {sLO 0.88} -state {sHI 0.99}
add_supply_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power

Feedback

states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the *create_pst* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows the states and voltages of a supply set function named ss1.power:

```
prompt> add_supply_state ss1.power \\
        -state {active_state1 0.88} \\
        -state {active_state2 0.92} \\
        -state {off_state off}
```

See Also

- add_port_state
- add_pst_state
- create_pst
- report_pst

---

add_tie_cells

Inserts tie cells into the current design.

Syntax

status *add_tie_cells*

```
[-objects object_name_or_collection]
[-tie_high_lib_cells lib_cells]
[-tie_low_lib_cells lib_cells]
```

Data Types

object_name_or_collection	collection
lib_cells	list

Arguments

`-objects` *object_name_or_collection*

Specifies the objects for tie cell insertion. Currently supported object types are pin, port, cell and lib_cell. If this option is not used, all constant pins in current design is considered for tie cell insertion. If the object type is cell, only the

Feedback

constant pins on the cell is considered. If the object type is lib_cell, only the constant pins of the cells that match the library cells are considered.

`-tie_high_lib_cells` *`lib_cells`*

Limits the tie high cells that can be used for this invocation of the command. When this argument is supplied, tie cell insertion only uses tie cells that are neither don't use nor don't touch, are for optimization purpose and in the library cell list. A library cell in the list that is not a tie cell is not used.

`-tie_low_lib_cells` *`lib_cells`*

Limits the tie low cells that can be used for this invocation of the command. When this argument is supplied, tie cell insertion only uses tie cells that are neither don't use nor don't touch, are for optimization purpose and in the library cell list. A library cell in the list that is not a tie cell is not used.

Description

This command adds tie cells to drive constant pins in the design, if there are useable tie cells in the library.

Examples

This command inserts tie cells into the current design.

```
prompt> add_tie_cells
prompt> add_tie_cells  -objects [get_pins *LOAD/D]
```

See Also

- set_lib_cell_purpose

---

add_to_begin_statement

Adds a statement to a begin statement.

Syntax

status *add_to_begin_statement*

```
begin_statement
rtl_statement
[-after after | -before before]
```

Data Types

```
begin_statement         collection
rtl_statement           collection
after                   collection
before                  collection
```

Feedback

Arguments

`begin_statement`

Specifies the statement of type "begin", in which new statements are added. This is a required argument.

`rtl_statement`

Specifies the statement which is to be added to the begin block.

`-after` *`after`*

Specifies the statement after which new statement is to be added to the begin statement. This option and *-before* option are mutually exclusive. If neither *-before* option or *-after* option is specified, the statement gets added at the end.

`-before` *`before`*

Specifies the statement before which new statement is to be added to begin statement. This option and *-after* option are mutually exclusive. If neither *-before* option or *-after* option is specified, the statement gets added at the end.

Description

This command adds statement to the begin statement. You can add multiple rtl_statements to the same begin statement but it should not be repeated. The *-after* option and *-before* option are mutually exclusive.

Examples

The following example adds a new statement 'u1/u1/RTL_ASSIGNMENT_96' to already present begin_end statement 'u1/u1/RTL_BEGIN_END_98'.

```
prompt > add_to_begin_statement [get_statements u1/u1/RTL_BEGIN_END_98]
 \\
[get_statements u1/u1/RTL_ASSIGNMENT_96]
{1}
```

See Also

---

add_to_bound

Assigns cells, ports, and groups to a bound in the current design.

Syntax

integer *add_to_bound*

Feedback

bound_object
cell_and_port_and_group_list

Data Types

bound_object	list
cell_and_port_and_group_list	list

Arguments

bound_object

Specifies the name or collection of a single bound. The bound object can be specified by using the *get_bounds* command. However it must return a collection of one and only one bound object.

cell_and_port_and_group_list

Specifies a list of cells, ports, and groups to assign to the bound. The list might contain names, patterns, or collections. It is an error to include a port which has already been assigned to another bound. If the bound is a move bound, it is an error to include a cell which has already been explicitly assigned to another move bound. If this bound is a group bound, it is an error to include a cell which has already been explicitly assigned to another group bound. If a cell is hierarchical, its child cells are also implicitly in the bound, as well as any cells added to its hierarchy in the future, unless the child cell is assigned to another bound. Cells that belong to a relative placement group cannot be individually added to a bound. All cells of a relative placement group must be added to a bound together. Group objects are only valid when adding to a repelling bound. Furthermore, repelling bounds might contain either cells and ports or groups, but not a mix.

Description

The *add_to_bound* command assigns cells, ports, and groups to an existing bound.

You can change the floorplan by assigning cells to the bound. The placer honors the new bound cells during coarse placement.

Examples

The following example assigns cells to a bound named "movebound1".

```
prompt> add_to_bound movebound1 { inv1 add1 }
1
```

The following example assigns the hierarchical cell "mid" to the bound. The bound implicitly contains all cells within "mid".

```
prompt> add_to_bound movebound1 [get_cells mid]
1
```

Feedback

The following example assigns all cells of a relative placement group "rp1" to the bound.

```
prompt> add_to_bound movebound1 [get_cells -of_objects rp1]
1
```

The following example assigns all repelling bound groups to the bound

```
prompt> add_to_bound repellingGroupBound1 \\
[get_groups -filter "is_repelling_bound_group==true"]
```

See Also

- create_bound
- get_bounds
- remove_bounds

- report_bounds

---

add_to_bundle

Adds objects to the specified bundle.

Syntax

status *add_to_bundle*

```
-bundle bundle
[-prepend | -before_object before_object]
objects
```

Data Types

```
bundle          collection
before_object   collection
objects         collection
```

Arguments

`-bundle` *bundle*

Specifies the bundle to which to add the objects.

`-prepend`

Adds the objects as the first objects in the bundle. By default, objects are added to the end of the bundle. This option the *-before_object* option are mutually exclusive.

Feedback

`-before_object` *`before_object`*

Adds the objects before the specified object in the bundle. By default, objects are added to the end of the bundle. This option is mutually exclusive with the *-prepend* option.

`objects`

Specifies the objects to add to the bundle. The objects must be nets, bundles or supernets.

The objects are added to the bundle in the order in which they are specified.

Description

This command adds one or more objects to the specified bundle. By default, the objects are added at the end of the bundle. You can insert objects at the start of the bundle with the *-prepend* option, or insert the objects before a specified object in the bundle with the *-before_object* option.

A different type of object than the type of bundle can't be added to the bundle.

Examples

The following example adds an object to the end of a bundle.

```
prompt> add_to_bundle -bundle [get_bundles BUNDLE_5] [get_nets Clk]
1
```

The following example adds an object to the start of a bundle.

```
prompt> add_to_bundle -bundle [get_bundles BUNDLE_5] \\
   -prepend [get_nets Reset]
1
```

See Also

- create_bundle
- get_bundles
- get_nets
- remove_bundles
- remove_from_bundle

---

add_to_case_statement

Adds a case-pair condition to a case statement.

Feedback

Syntax

status *add_to_case_statement*

```
case_statement
[-case statement  -expression expression] | [-default default_statement]
```

Data Types

```
case_statement          collection
statement               collection
expression              collection
default_statement       collection
```

Arguments

case_statement

Specifies the statement of type "case", in which new statements are added. This is a required argument.

-case *statement*

Specifies the statement which is to be added to the case pair condition. This option and *-expression* option are mutually inclusive.

-expression *expression*

Specifies the expression for the new case pair condition. If -case is given expression must be given. Expression cab be port, net, bus_port, bus_net, literal, expression or list. This option and *-case* option are mutually inclusive.

-default *default_statement*

Specifies the default statement which is to be added to the case statement. This option is mutually exclusive with *-expression* option and *-case* option.

Description

This *add_to_case_statement* command adds a case-pair condition to the case statement. You can add multiple case_pair conditions to the same case statement but it should not be repeated. Also, you can add default statement to the case statement using this command. The *-expression* option and *-default* option are mutually exclusive.

Examples

The following example adds a new case-pair condition to already present case statement 'u1/u1/RTL_CASE_6'.

```
prompt> add_to_case_statement [get_statements u1/u1/RTL_CASE_6] \\
-case [get_statements u1/u1/RTL_LITERAL_3] \\
-expression [get_statements u1/u1/RTL_LITERAL_5]
{1}
```

Feedback

See Also

- get_statements
- remove_statements

---

add_to_collection

Adds objects to a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *add_to_collection*

```
[-unique]
collection1
object_spec
```

Data Types

collection1	collection
object_spec	list

Arguments

`-unique`

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

collection1

Specifies the base collection to which objects are to be added. This collection is copied to the result collection, and objects matching *object_spec* are added to the result collection. The *collection1* option can be the empty collection (empty string), subject to some constraints, as explained in the DESCRIPTION section.

object_spec

Specifies a list of named objects or collections to add.

If the base collection is heterogeneous, only collections can be added to it.

If the base collection is homogeneous, the object class of each element in this list must be the same as in the base collection. If it is not the same class, it is ignored. From heterogeneous collections in the *object_spec*, only objects of the same class of the base collection are added. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

Feedback

The *object_spec* has some special rules when the base collection is empty, as explained in the DESCRIPTION section.

Description

The *add_to_collection* command allows you to add elements to a collection. The result is a new collection representing the objects in the *object_spec* added to the objects in the base collection.

Elements that exist in both the base collection and the *object_spec*, are duplicated in the resulting collection. Duplicates are not removed unless you use the *-unique* option. If the *object_spec* is empty, the result is a copy of the base collection.

If the base collection is homogeneous, the command searches in the database for any elements of the *object_spec* that are not collections, using the object class of the base collection. If the base collection is heterogeneous, all implicit elements of the *object_spec* are ignored.

When the *collection1* argument is the empty collection, some special rules apply to the *object_spec*. If the *object_spec* is non-empty, there must be at least one homogeneous collection somewhere in the *object_spec* list (its position in the list does not matter). The first homogeneous collection in the *object_spec* list becomes the base collection and sets the object class for the function. The examples show the different errors and warnings that can be generated.

The *append_to_collection* command has similar semantics as the *add_to_collection* command; however, the *append_to_collection* command can be much more efficient in some cases. For more information about the command, see the man page.

For background on collections and querying of objects, see the *collections* man page.

Examples

The following example uses the *get_ports* command to get all of the ports beginning with 'mode' and then adds the "CLOCK" port.

```
prompt> set xports [get_ports mode*]
{mode[0] mode[1] mode[2]}
prompt> add_to_collection $xports [get_ports CLOCK]
{mode[0] mode[1] mode[2] CLOCK}
```

The following example adds the cell u1 to a collection containing the SCANOUT port.

```
prompt> set so [get_ports SCANOUT]
{SCANOUT}
prompt> set u1 [get_cells u1]
{u1}
prompt> set het [add_to_collection $so $u1]
{u1}
prompt> query_objects -verbose $het
{{port SCANOUT} {cell u1}}
```

Feedback

The following examples show how the *add_to_collection* command behaves when the base collection is empty. Adding two empty collections yields the empty collection. Adding an implicit list of only strings or heterogeneous collections to the empty collection generates an error message, because no homogeneous collections are present in the *object_spec* list. Finally, if one homogeneous collection is present in the *object_spec* list, the command succeeds, even though a warning message is generated. The example uses the variable settings from the previous example.

```
prompt> sizeof_collection [add_to_collection "" ""]
0

prompt> set A [add_to_collection "" [list a $het c]]
Error: At least one homogeneous collection required for argument
 'object_spec'
       to add_to_collection when the 'collection' argument is empty
 (SEL-014)

prompt> add_to_collection "" [list a $het $sp]]
Warning: Ignored all implicit elements in argument 'object_spec'
         to add_to_collection because the class of the base collection
         could not be determined (SEL-015)
{SCANOUT u1 SCANOUT}
```

See Also

- append_to_collection
- collections
- query_objects
- remove_from_collection
- sizeof_collection

---

add_to_edit_group

Adds objects to an edit group in the current design.

Syntax

collection *add_to_edit_group*

```
edit_group_object
object_list
```

Data Types

```
edit_group_object   list
object_list         list
```

Feedback

Arguments

edit_group_object

Specifies the name or collection of a single edit group. The edit group object can be specified by using the *get_edit_groups* command, however it must return a collection of exactly one edit group object.

object_list

Specifies a list of objects to add to the edit group. The list can contain names, patterns, or collections. It is an error to include an object which is already contained within another edit group.

It is also an error to include an object that belongs to a different design, unless the object is itself an edit_group from a lower level of physical hierarchy, and does not belong to any other edit_groups in the current design, and there are no other edit_groups from that lower level of physical hierarchy that belong to any edit_groups in the current design. That is, only one edit_group from a particular lower level of physical hierarchy may belong to any edit_group in the top level at any time.

If an edit_group object from a lower level of physical hierarchy is included in the *object_list* and the above conditions are met, then the object will be placed into the edit_group's *hier_objects* collection. All other objects will be placed into the edit_group's *objects* collection.

Description

The *add_to_edit_group* command adds objects to an existing edit group. The command returns a collection containing the modified edit group as the only object, or TCL_ERROR if the command fails.

Examples

The following example adds objects to an edit group named "edit_group1"

```
prompt> add_to_edit_group edit_group1 { U31 voltage_group2 }
{"edit_group1"}
```

See Also

- create_edit_group
- get_edit_groups
- remove_edit_groups
- remove_from_edit_group

Feedback

add_to_function

Adds a statement to a function statement.

Syntax

```
collection add_to_function
function
rtl_statement
[-after after | -before before]
```

Data Types

function	collection
rtl_statement	collection
after	collection
before	collection

Arguments

`function`

Specifies the statement of type function in which to add new statements. This is a required argument.

`rtl_statement`

Specifies the statement which is to be added to the function.

`-after` *after*

Specifies the statement after which new statement is to be added to function. '-before' and "-after' are mutually exclusive. If neither of '-before' or '-after' is specified, the statement gets added at the end.

`-before` *before*

Specifies the statement before which new statement is to be added to function. '-before' and "-after' are mutually exclusive. If neither of '-before' or '-after' is specified, the statement gets added at the end.

Description

This command adds statement to the function.

Examples

The following example adds a new statement 'u1/u1/RTL_ASSIGNMENT_96' to already present function 'u1/u1/RTL_FUNCTION_98'.

```
prompt > add_to_function [get_statements u1/u1/RTL_FUNCTION_98]
 [get_statements u1/u1/RTL_ASSIGNMENT_96]
{1}
```

Feedback

---

add_to_group

Adds objects to the group in the current design.

Syntax

integer *add_to_group*

```
group
object_list
```

Data Types

```
group          list
object_list    list
```

Arguments

group

Specifies the name or collection of groups. The group object can be specified by using the *get_groups* command.

object_list

Specifies a list of objects to add to the group. The list can contain names, patterns, or collections. It is an error to include an object that does not belong to the current design.

Supported object classes are cell, pin, port, net, module, shape, placement_blockage, site_row, via, track, bound, bound_shape, routing_rule, routing_blockage, routing_guide, io_guide, io_ring, voltage_area, voltage_area_shape, pin_blockage, pin_guide, pg_region, edit_group, terminal, routing_corridor, routing_corridor_shape, grid, matching_type, site_array, supernet, shaping_blockage, constraint_group, topological_constraint, via_region, topology_edge, topology_node, overlap_blockage and group.

Supported object classes for repelling bound groups are cell.

Description

The *add_to_group* command adds objects to the group. The command returns the number of objects added into the group. If the command fails, it returns a TCL_ERROR.

Feedback

Examples

The following example adds two nets n12, n13 to the group named "group1"

```
prompt> add_to_group group1 [ get_nets { n12 n13} ] }
2
```

See Also

---

add_to_io_guide

Adds pads to an I/O guide in the current design.

Syntax

int *add_to_io_guide*

```
[-before pad_object]
io_guide_object
pad_cell_list
```

Data Types

pad_object	pad cell
io_guide_object	list
pad_cell_list	list

Arguments

`-before pad_object`

Specifies the name or collection of a single library cell. The pads are inserted before the specified pad cell. By default, new cells are added at the end of the list.

io_guide_object

Specifies the name or collection of a single I/O guide. The *io_guide_object* can be specified by using the *get_io_guides* command. However it must return a collection of one and only one io_guide object.

Feedback

pad_cell_list

Specifies a list of pads to add to the I/O guide. The list can contain names, patterns, or collections. It is an error to include a cell or port which has already been assigned to another io_guide or one that belongs to a different design.

Description

The *add_to_io_guide* command adds pad cells to an existing I/O guide. You can change the floorplan by adding cells to the I/O guide. The I/O placer honors the new io_guide cells during coarse placement.

The command returns 1 if the command succeeds, 0 if it fails, or TCL_ERROR if there is a command syntax error.

Examples

The following example adds cells to an io_guide named "io_guide1"

```
prompt> add_to_io_guide io_guide1 { bus_4 }
1
```

The following example adds cells to an io_guide named "io_guide1" before pad3.

```
prompt> add_to_io_guide -before bus_4 io_guide1 { bus_2 bus_3 }
1
```

See Also

---

add_to_io_ring

Adds guides to an I/O ring in the current design.

Syntax

int *add_to_io_ring*

io_ring_object
guide_list

Feedback

Data Types

```
io_ring_object    list
guide_list        list
```

Arguments

io_ring_object

Specifies the name or collection of a single I/O ring. The *io_ring_object* can be specified by using the *get_io_rings* command. However it must return a collection of one and only one io_ring object.

guide_list

Specifies a list of I/O guides to add to the I/O ring. The list can contain I/O guide names, patterns, or collections. It is an error to include a I/O guide which has already been assigned to another I/O ring.

Description

The *add_to_io_ring* command adds I/O guides to an existing I/O ring.

You can change the floorplan by adding I/O guides to the I/O ring. The I/O placer honors the new I/O ring guides during I/O placement.

The command returns 1 if the command succeeds, 0 if it fails, or TCL_ERROR if there is a command syntax error.

Examples

The following example adds guides to an I/O ring named "io_ring1"

```
prompt> add_to_io_ring io_ring1 { io_guide1 io_guide2 }
1
```

Feedback

add_to_matching_type

Assigns cells, pins, and terminals to the matching type.

Syntax

int *add_to_matching_type*

```
matching_type
object_list
```

Data Types

```
matching_type       list
object_list         list
```

Arguments

matching_type

Specifies the name or collection of a single matching type. The matching type can be specified by using the *get_matching_types* command. However it must return a collection of one and only one matching type.

object_list

Specifies a list of cells, pins, and terminals to add to the matching type. The list can contain names, patterns, or collections. It is an error to add an object which is already in another matching type. Each object can exist in at most one matching type in the block.

Description

The *add_to_matching_type* command assigns cells, pins, and terminals to an existing matching type.

When I/O placement is performed, objects can be connected only to other objects with the same matching type. The matching type exists only in the block in which it was created, but its containing objects can span into subblocks. As a result, the matching types for the current block can apply to objects in subblocks when performing I/O placement from the current block, but matching types created in other blocks are not visible from the current block.

Examples

The following example assigns cells to a matching type named "myMatchingType1".

```
prompt> add_to_matching_type myMatchingType1 [get_cells inv1]
1
```

Feedback

See Also

- create_matching_type

---

add_to_multisource_clock_sink_group

Adds clock sinks to a sink group defined for multisource clock tap assignment

Syntax

status *add_to_multisource_clock_sink_group*

```
-name name
-sinks pin_or_port_list
```

Data Types

```
name                 string
pin_or_port_list     collection
```

Arguments

`-name name`

Defines the name of the sink group to which sinks are to be added. This is a required option. Sink groups are defined using the *create_multisource_clock_sink_group* command.

`-sinks pin_or_port_list`

Specifies a list of sinks that should get added to the sink list of the sink group given by the option *-name*. This is a required option.

Description

The *add_to_multisource_clock_sink_group* command is used to add clock tree sinks to a sink group defined for multisource clock tap assignment.

The list of assigned sinks to a sink group can be obtained by accessing the sink group attribute *sinks*.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

This example adds the clock tree sink reg1/CK to sink group sink_group1.

```
prompt> add_to_multisource_clock_sink_group -name sink_group1 \\
-sinks [get_pins reg1/CK]
```

---

add_to_must_join_ports

Combines ports into a new or existing must-join port group.

Syntax

status *add_to_must_join_ports*

port_list

Data Types

port_list collection

Arguments

port_list

Specifies a port name list or a port collection to form into a must-join group. Ports must be in the current block.

Feedback

Description

The *add_to_must_join_ports* command combines the specified ports into a must-join port group. The command creates a new must-join port group if none of the ports in port_list are already in a must-join port group. If one of the ports is already in a must-join port group then the other ports are added to the existing group. If two or more ports are already in must-join port groups then the groups are merged into a single group and any unassociated ports are added to the resulting group.

If the port list contains only a single port, the command removes the port from any must-join port group.

Examples

The following example creates a must-join port group.

```
prompt> add_to_must_join_ports {A0 A1 A2}
1
```

The following example adds additional ports to the earlier must-join port group.

```
prompt> add_to_must_join_ports {A0 A3 A4 A5}
1
```

The following example remove a port from its must-join port group.

```
prompt> add_to_must_join_ports {A5}
1
```

---

add_to_net

Adds shapes, vias and via_matrixes to a net in the current design.

Syntax

integer *add_to_net*

```
net
shape_and_via_list
```

Data Types

```
net                 collection
shape_and_via_list collection
```

Feedback

Arguments

net

Specifies the net to which to add shapes, vias and via_matrixes.

shape_and_via_list

Specifies the shapes, vias and via_matrixes to add to the net. The list might contain names, patterns, or collections. It is an error to include a shape, via or via_matrix which has already been assigned to another net. Text shapes might not be added to a net.

Description

The *add_to_net* command adds shapes, vias and via_matrixes to an existing net. Each shape, via and via_matrix might belong to one and only one net. Rects, polygons, paths, simple vias, simple array vias, and custom vias, via_matrixes might belong to a net. A text shape might not belong to any net.

Examples

The following example adds path shapes to a net.

```
prompt> add_to_net net1 [get_shapes PATH_16_*]
1
```

The following example adds simple vias to a net.

```
prompt> add_to_net net1 [get_vias VIA_S_*]
1
```

---

add_to_net_bus

Adds the specified existing net to the existing net bus in the current design.

Feedback

Syntax

collection *add_to_net_bus*

```
net_bus
net
```

Data Types

```
net_bus    collection
net        collection
```

Arguments

net_bus

Specifies the net bus in which *net* needs to be added.

net

Specifies the net to add to the net bus. The *net* should have the same base name as the *net_bus*. This net must be existing.

Description

This command adds the existing net to the existing net bus in the current design. Net bus numbering must increment in consecutive order; out-of-order bus nets are not allowed and the tool issues an error message.

The command returns the updated net bus as a collection, an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

Examples

The following example creates a net bus named *bus1*, then adds net bus1[8] to the net bus named *bus1* having nets from 1 to 7. The third command tries to add an illegal bus net; bus net numbers must increment in consecutive order.

```
prompt> create_net_bus -create_nets bus1[0:7]
{bus1}

prompt> add_to_net_bus bus1 bus1[8]
{bus1}

prompt> add_to_net_bus bus1 bus1[10]
Error: Net addition creates a hole in the net bus. (NDM-120)
```

See Also

- get_net_buses

Feedback

- remove_from_net_bus
- remove_net_buses
- report_net_buses

---

add_to_package_statement

Adds a statement to a package statement.

Syntax

```
collection add_to_package_statement
package_statement
rtl_statement
[-after after | -before before]
```

Data Types

```
package_statement      collection
rtl_statement          collection
after                  collection
before                 collection
```

Arguments

`package_statement`

Specifies the statement of type package in which to add new statements. This is a required argument.

`rtl_statement`

Specifies the statement which is to be added to the package block.

`-after after`

Specifies the statement after which new statement is to be added to package statement. '-before' and "-after' are mutually exclusive. If neither of '-before' or '-after' is specified, the statement gets added at the end.

`-before before`

Specifies the statement before which new statement is to be added to package statement. '-before' and "-after' are mutually exclusive. If neither of '-before' or '-after' is specified, the statement gets added at the end.

Description

This command adds statement to the package statement.

Feedback

Examples

The following example adds a new statement 'u1/u1/RTL_ASSIGNMENT_96' to already present package_end statement 'u1/u1/RTL_PACKAGE_98'.

```
prompt > add_to_package_statement [get_statements u1/u1/RTL_PACKAGE_98]
 [get_statements u1/u1/RTL_ASSIGNMENT_96]
{1}
```

See Also

- get_statements

---

add_to_pin_blockage

Adds pins, nets, or ports to a pin blockage in the current design.

Syntax

status *add_to_pin_blockage*

```
pin_blockages
objects
```

Data Types

pin_blockages	collection
objects	collection

Arguments

pin_blockages

Specifies the pin blockages to which to add the specified objects.

objects

Specifies the physical pins, nets, or ports to add to the pin blockages. The specified objects must have the same type as the objects that already exist in the pin blockage.

Description

The *add_to_pin_blockage* command adds physical pins, nets, or ports to the existing pin blockages. The specified objects can be added to multiple pin blockages.

Each pin blockage can contain objects of only one type, either pin, net, or port. It cannot contain a mixture of object types. If a pin blockage already contains pins, it cannot be assigned nets or ports. If a pin blockage already contains nets, it cannot be assigned pins or ports. If a pin blockage already contains ports, it cannot be assigned pins or nets.

Feedback

Examples

The following example adds nets to a pin blockage named PIN_BLOCKAGE_1.

```
prompt> add_to_pin_blockage PIN_BLOCKAGE_1 [get_nets net*]
1
```

See Also

- create_pin_blockage
- get_pin_blockages
- report_pin_blockages

---

add_to_pin_guide

Adds pins, nets, or ports to a pin guide in the current design.

Syntax

status *add_to_pin_guide*

```
pin_guides
objects
```

Data Types

```
pin_guides      collection
objects         collection
```

Arguments

pin_guides

Specifies the pin guides to which to add the specified objects.

objects

Specifies the physical pins, nets, individual or bundled, or ports to add to the pin guides. The specified objects must have the same type as the objects that already exist in the pin guide. Currently bundles of supernets is not supported. If bundle of supernets is specified then it is skipped with a warning message.

Feedback

Description

The *add_to_pin_guide* command adds physical pins, nets, bundles of nets, or ports to existing pin guides. If the parent of a pin guide is the current design, ports or nets can be added to the pin guide. If the parent of a pin guide is a hierarchical cell, pins or nets can be added to the pin guide. Pins, nets, or ports can be added to multiple pin guides.

Each pin guide can contain objects of only one type, either pin, net, or port. It cannot contain a mixture of object types. If a pin guide already contains pins, it cannot be assigned nets or ports. If a pin guide already contains nets, it cannot be assigned pins or ports. If a pin guide already contains ports, it cannot be assigned pins or nets.

Examples

The following example adds nets to a pin guide named PIN_GUIDE_1.

```
prompt> add_to_pin_guide PIN_GUIDE_1 [get_nets net*]
1
```

---

add_to_placement_attraction

Assigns cells to a placement_attraction in the current design.

Syntax

integer *add_to_placement_attraction*

```
placement_attraction_object
cell_list
```

Feedback

Data Types

placement_attraction_object list
cell_list list

Arguments

placement_attraction_object

Specifies the name or collection of a single placement_attraction. The placement_attraction object can be specified by using the *get_placement_attractions* command. However it must return a collection of one and only one placement_attraction object.

cell_list

Specifies a list of cells to assign to the placement_attraction. The list may contain names, patterns, or collections. If a cell is hierarchical, its child cells are also implicitly in the placement_attraction, as well as any cells added to its hierarchy in the future. Cells that belong to a relative placement group cannot be individually added to a placement_attraction. All cells of a relative placement group must be added to a placement_attraction together.

Description

The *add_to_placement_attraction* command assigns cells to an existing placement_attraction.

You can change the floorplan by assigning cells to the placement_attraction. The placer honors the new placement_attraction cells during coarse placement.

Examples

The following example assigns cells to a placement_attraction named "placement_attraction1".

```
prompt> add_to_placement_attraction placement_attraction1 { inv1 add1 }
1
```

The following example assigns the hierarchical cell "mid" to the placement_attraction. The placement_attraction implicitly contains all cells within "mid".

```
prompt> add_to_placement_attraction placement_attraction1 [get_cells mid]
1
```

The following example assigns all cells of a relative placement group "rp1" to the placement_attraction.

```
prompt> add_to_placement_attraction placement_attraction1 [get_cells
 -of_objects rp1]
1
```

Feedback

See Also

- create_placement_attraction
- get_placement_attractions
- remove_placement_attractions
- remove_from_placement_attraction
- report_placement_attractions

---

add_to_port_bus

Adds the specified existing port to the existing port bus in the current design.

Syntax

collection *add_to_port_bus*

```
port_bus
port
```

Data Types

```
port_bus   collection
port       collection
```

Arguments

port_bus

Specifies the port bus in which, port needs to be added.

port

Specifies the port to be added to the port bus. The *port* should have the same base name as the *port_bus*. This port must be existing.

Description

This command adds the existing port to the existing port bus in the current design. Port bus numbering must increment in consecutive order; out-of-order bus ports are not allowed and causes the tool to issue an error message.

The command returns the updated port bus as a collection, an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

Feedback

Examples

The following example creates a port bus named bus1, then adds port bus1[8] to the port bus named *bus1* having ports from 1 to 7. The third command tries to add an illegal bus port; bus port numbers must increment in consecutive order.

```
prompt> create_port_bus -create_ports bus1[0:7]
{bus1}

prompt> add_to_port_bus bus1 bus1[8]
{bus1}

prompt> add_to_port_bus bus1 bus1[10]
Error: Port addition creates a hole in the port bus. (NDM-115)
```

add_to_routing_corridor

Associates nets, supernets, and their bundles with a routing corridor.

Syntax

status *add_to_routing_corridor*

```
routing_corridor
object_list
```

Data Types

```
routing_corridor   list
object_list        list
```

Arguments

routing_corridor

Specifies the routing corridor with which to associate the specified nets.

This is a required option.

Feedback

object_list

Specifies the nets and supernets, individual or bundled to associate with the routing corridor.

This is a required option.

Description

This command associates nets, supernets, and their bundles with a routing corridor.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example associates the nets named *net_a* and *net_b* with the routing corridor named *corridor_a*.

```
prompt> add_to_routing_corridor \\
   corridor_a [get_nets [list net_a net_b]]
```

The following example associates the supernet named *supernet_1* with the routing corridor named *corridor_a*.

```
prompt> add_to_routing_corridor \\
   corridor_a supernet_1
```

See Also

---

add_to_rp_group

Adds cell, relative placement group or relative placement blockage to a relative placement group in the current design.

Feedback

Syntax

integer *add_to_rp_group*

```
rp_group_object
[-row     row_number]
[-column  column_number]
[-override_alignment left | right]
-cells cell_list
   [-num_rows number_of_rows]
   [-num_columns number_of_columns]
   [-pin_name pin_name]
   [-orientation direction]
   [-free_placement]
   [-height object_height]
   [-width object_width]|
-rp_group rp_group_object |
-blockage blockage_name
   [-width object_width]
   [-height object_height]
   [-allow_overlap]
```

Data Types

rp_group_object	collection
row_number	integer
column_number	integer
left	string
right	string
cell_list	list
number_of_rows	integer
number_of_columns	integer
pin_name	string
direction	list
object_height	integer
object_width	integer
blockage_name	string

Arguments

rp_group_object

Specifies the name or collection of a single relative placement group, to which the objects will be added. The relative placement object can be specified by using the *get_rp_groups* command. However it must return a collection of one and only one relative placement group.

-row *row_number*

Specifies the row position in which to add the object. If you do not specify the row position, the default is zero.

Feedback

`-column` *`column_number`*

Specifies the column position in which to add the object. If you do not specify the column position, the default is zero.

`-override_alignment` *`left | right`*

Specifies the type of the override alignment for the specified relative placement object in its column. The specified override alignment will override the alignment type that was inherited from its parent relative placement group. The right override alignment is not supported for the multi column relative placement cell.

`-cells` *`cell_list`*

Specifies a list of cells to add to the relative placement group. If this command option is used with *free_placement* command option then all the cells specified in the list will be added otherwise, only the first cell of the list will be added to the RP group location. The list may contain names, patterns, or collections. It is an error to include a cell, which has already been assigned to another relative placement group. The hard macro cells can also be added to RP group.

`-num_rows` *`number_of_rows`*

Specifies the number of rows to which you add the cell(s). The default is 1 if you do not specify this option. This option can also be used with *-free_placement* for adding free placement cells.

`-num_columns` *`number_of_columns`*

Specifies the number of columns to which you add the cell(s). The default is 1 if you do not specify this option. The pin alignment is not supported for a cell that occupies multiple columns. This option can also be used with *-free_placement* for adding free placement cells.

`-pin_name` *`pin_name`*

Specifies the name of the pin to use for pin alignment of this cell with other cells in a group. This overrides the default pin name specified for the relative placement group into which it is being added. This option can only be used when adding a leaf cell with the *-cells* option. The option is not applicable on hard macro cells.

`-orientation` *`direction`*

Specifies the placement orientation of the cell, with respect to the group in which the cell is being added. You can specify a list of possible orientations, and the tool chooses the first legal orientation for the cell. The option is not applicable on hard macro cells.

Feedback

`-free_placement`

Specifies that the given cells will not have a fixed relative location inside the relative placement group. The default value is false and it can be used only with the -cells option. This option is used along with *-num_rows*, *-num_columns*, *-height* and *-width* options. The *-num_rows* and *-num_columns* options will specify number of rows and columns to which free placement cells will be added. The *-height* and *-width* options will specify the height and width of the free placement region.

`-height` *`object_height`*

Specifies the height of the blockage being added when used with the *-blockage* option or the height of the free placement region when used with *-free_placement*. option. The unit for height is the height of the site row for a particular library. If you do not specify the height, it defaults to the site row height.

`-width` *`object_width`*

Specifies the width of the blockage being added when used with *-blockage* or the width of the free placement region when used with *-free_placement*. The unit for width is the width of the site row for a particular library. If you do not specify the width, it defaults to the width of the site for horizontal_compression *tiling_type* and for other tiling types it is the width of the column into which the blockage is being added. If you do not specify the width with *-free_placement* option, the width of free placement region defaults to the width of the site row.

`-rp_group` *`hier_rp_group_object`*

Specifies the relative placement group name or collection to add to the relative placement group. It is an error to include a relative placement group, which has already been added.

`-blockage` *`blockage_name`*

Specifies the name of the blockage to add to the relative placement group. It is an error to provide a *blockage_name*, which has already been used for some other relative placement blockage.

`-allow_overlap`

Specifies that the blockage can be placed over fixed objects. It can also overlap with relative placement blockages, but cannot overlap with the relative placement cells. The blockage cannot overlap with fixed objects if the option is not given.

Description

The *add_to_rp_group* command adds cells, relative placement group or relative placement blockage to existing relative placement group. The added object is placed in a particular

Feedback

lattice position of the group as specified by a *row* and *column* options. The hard macro cells also can be added to the relative placement group. The user has to follow a flow when hard macros are present in the relative placement group. Please refer to user guide for more details.

Examples

The following example uses *add_to_rp_group* to add a cell to an existing relative placement group and then adds that group hierarchically to another existing group.

```
prompt> get_rp_groups grp_ripple
{grp_ripple}

prompt> add_to_rp_group grp_ripple -cells carry_in_1 -row 1 -column 2
1

prompt> add_to_rp_group top_group -rp_group grp_ripple -row 2 -column 2
1
```

The following example uses *add_to_rp_group* to add a blockage to an existing relative placement group.

```
prompt> add_to_rp_group grp_ripple -blockage grp_ripple_blkg2 \\
   -row 2 -column 2 -allow_overlap
1
```

The following example uses *add_to_rp_group* to add free placement cells to an existing relative placement group.

```
prompt> add_to_rp_group grp_ripple \\
   -cells {carry_in_1 carry_in_2 carry_out_1} -free_placement \\
   -row 1 -column 1 -height 2 -width 5 -num_rows 2 -num_columns 2
```

---

add_via_mapping

Adds via mapping options for redundant via insertion.

Feedback

Syntax

status *add_via_mapping*

```
-from via_pattern
-to list_of_destination_vias
[-weight weight]
[-transform all | flip | none | rotate]
[-force]
| -from_icc_file script
```

Data Types

```
via_pattern               string
list_of_destination_vias  list
weight                    integer
script                    string
```

Arguments

`-from via_pattern`

Specifies the vias to be replaced during redundant via insertion.

A via pattern has two parts: viaDefName and site_spec mxn. viaDefName is via definition name. MxN specifies the number of contacts in the horizontal (M) and vertical (N) directions.

This option supports simple vias.

This is a required option and must be specified.

`-to list_of_destination_vias`

Specifies the list of vias to insert during redundant via insertion. This is a required option and must be specified.

This option supports simple vias and custom vias. If a custom via is specified, the target MxN dimension must be 1x1.

`-weight weight`

Specifies the weight of contacts for the vias inserted during redundant via insertion. The weight is an integer between 1 and 30 (inclusive). Via mappings with a higher weight are preferred over via mappings with a lower weight.

The default is 1 for all via mappings.

`-transform all | flip | none | rotate`

Specifies the types of rotated via arrays that can be used during signal routing and redundant via insertion.

Feedback

The definition for each mode is:

- *none* : Do not rotate or swap via arrays.
- *flip* : Use 1 x N and N x 1 via arrays as rotated equivalent vias.
- *rotate* : Rotate line via arrays instead of flipping (swapping row and column numbers).
- *all* : Use all four possible via arrays. This option is the default.

`-force`

Overwrites via mappings with the same "from" and "to" via patterns, if it already exists.

`-from_icc_file` *script*

Specifies the script file that contains via mapping settings from IC Compiler *define_zrt_redundant_vias* command.

Before applying the via mapping settings in the script file, all existing via mappings are removed first.

This option is mutually exclusive with all other options.

Description

This command sets options for redundant via insertion. The redundant via definitions are saved in the design.

This command can also accept a script file that contains the *define_zrt_redundant_vias* command from IC Compiler.

Examples

The following example sets the options for via replacement with double vias:

```
prompt> add_via_mapping  -from {VIA12 1x1} \\
   -to { VIA12 1x2}
```

The following example sets the options for via replacement with weight of 2:

```
prompt> add_via_mapping -from {VIA23_r90 1x1}  \\
   -to { VIA23 2x1} -weight 2
```

The following example sets the options for via replacement by a script file:

```
prompt> add_via_mapping -from_icc_file RVI.tcl
```

The RVI.tcl has following content:

```
        set VIA_OPT_LIST {
```

Feedback

```
    {"VIA23"            "VIA23"         2       1       2}
    {"VIA23_VV"         "VIA23_VV"      2       1       2}
    {"VIA23"            "VIA23_FBD"     1       1       9}
    {"VIA23"            "VIA23_FBS"     1       1       8}
    {"VIA23"            "VIA23_PBD"     1       1       7}
    {"VIA23_LONG_V"     "VIA23_PBD"     1       1       8}
    {"VIA23_LONG_H"     "VIA23_FBD"     1       1       9}
}
set _from_list ""
set _to_list ""
set _xfactor_list ""
set _yfactor_list ""
set _to_via_weight_list ""

foreach {_from _to _xfactor _yfactor _to_via_weight} [join $VIA_OPT_LIST]
 {
    set _from_list              "$_from_list            $_from"
    set _to_list                "$_to_list              $_to"
    set _xfactor_list           "$_xfactor_list         $_xfactor"
    set _yfactor_list           "$_yfactor_list         $_yfactor"
    set _to_via_weight_list     "$_to_via_weight_list   $_to_via_weight"
}
define_zrt_redundant_vias \\
-from_via       $_from_list \\
-to_via         $_to_list \\
-to_via_x_size  $_xfactor_list \\
-to_via_y_size  $_yfactor_list \\
-to_via_weights $_to_via_weight_list
```

See Also

- report_via_mapping

---

alias

Creates a pseudo-command that expands to one or more words, or lists current alias definitions.

Syntax

string *alias* [*name*] [*def*]

Data Types

```
name      string
def       string
```

Feedback

Arguments

name

Specifies a name of the alias to define or display. The name must begin with a letter, and can contain letters, underscores, and numbers.

def

Expands the alias. That is, the replacement text for the alias name.

Description

The *alias* command defines or displays command aliases. With no arguments, the *alias* command displays all currently defined aliases and their expansions. With a single argument, the *alias* command displays the expansion for the given alias name. With more than one argument, an alias is created that is named by the first argument and expanding to the remaining arguments.

You cannot create an alias using the name of any existing command or procedure. Thus, you cannot use *alias* to redefine existing commands.

Aliases can refer to other aliases.

Aliases are only expanded when they are the first word in a command.

Examples

Although commands can be abbreviated, sometimes there is a conflict with another command. The following example shows how to use *alias* to get around the conflict:

```
prompt> alias q quit
```

The following example shows how to use *alias* to create a shortcut for commonly-used command invocations:

```
prompt> alias include {source -echo -verbose}

prompt> alias rt100 {report_timing -max_paths 100}
```

After the previous commands, the command *include script.tcl* is replaced with *source -echo -verbose script.tcl* before the command is interpreted.

The following examples show how to display aliases using *alias*. Note that when displaying all aliases, they are in alphabetical order.

```
prompt> alias rt100
rt100  report_timing -max_paths 100

prompt> alias
include  source -echo -verbose
q  quit
rt100  report_timing -max_paths 100
```

Feedback

- unalias

---

align_block_pins

Aligns the connected pins from the anchor block to the alignee block using the terminals of the anchor pins as references. Aligns or generates the connected alignee pin terminals on the alignee block.

Syntax

int *align_block_pins*

```
[-anchor anchor]
[-alignee alignee]
[-change_layer]
[-change_layer_width]
[-change_layer_height]
[-off_edge]
[-report_prefix]
```

Data Types

```
anchor block_instance_name
alignee block_instance_name
```

Arguments

`-anchor` *anchor*

Specifies a physical block instance or the top-level design whose pins or ports serve as anchors for aligning two blocks.

`-alignee` *alignee*

Specifies a physical block instance or the top-level design that is an immediate sibling, nearest child, or nearest parent block of the anchor.

`-change_layer`

Changes the layer of the alignee pins to match the layer of the connected pin. This option is mutually exclusive with -change_layer_width and -change_layer_height.

`-change_layer_width`

Changes the layer and width of the alignee pins to match the layer and width of the connected anchor pin.

Feedback

`-change_layer_height`

Changes the layer and height of the alignee pins to match the layer and height of the connected anchor pin.

`-off_edge`

Allow alignment of off-edge pins. If both the anchor and alignee pins are off-edge pins, the lower-left (LL) corner of the alignee pin will match the LL corner of the anchor pin. If the off-edge anchor pin is located outside the boundary of the alignee block, the alignee pin does not move.

`-report_prefix`

Specifies the prefix of the report file name. The default file name format is ${anchor}_to_${alignee}_not_aligned_details_${timestamp}.

Description

This command aligns the pins on two adjacent physical blocks that share common connections between them. It supports either immediate sibling or parent-child block relationships. The pin on the *alignee block* will be moved to align with the corresponding pin on the *anchor block*. Once the command completes the execution, the pins between the two blocks that can be aligned will be positioned on the same horizontal or vertical axis. If there are no terminals on the moved alignee pin, a terminal will be automatically created on the same metal layer as the corresponding anchor pin.

Note that *align_block_pins* only considers two-pin nets that connect the alignee and anchor blocks. If the nets also involve one or more other hierarchical blocks, *align_block_pins* does not try to align those pins. Pin alignment itself does not consider side, layer, offset, and other pin constraints specified by the *set_individual_pin_constraints*, *create_block_pin_constraint*, or *read_pin_constraints* commands. To place pins while honoring constraints set by these commands, use the *place_pins* command.

You should only use the *align_block_pins* command when two blocks are physically close and have no obstacles between them. This command does not perform overlap checking or blockage avoidance. Alignment is not performed and the pin is not moved if any of the following are true:

- Anchor pin has no net connected.
- Anchor block is pure logical block.
- Anchor pin belong to a power or ground or constrain net.
- Anchor pin has mutli-fanout.
- Anchor pin has empty or multiple terminal.

Feedback

- Alignee block is a hard marco.
- Connected alignee pin has multi-terminal or fixed location.

Pins on the *anchor block* that cannot be aligned will be categorized and included in the report generated at the end of the command. The reason why each pin on the anchor block cannot be aligned will be detailed in the generated report file.

Examples

The following example moves the pins on the alignee block so that they align either horizontally or vertically with their connected pins on the anchor block.

```
prompt> align_block_pins -anchor I_DATA_PATH -alignee I_ALU
```

The following example shows how to use the command when the anchor is the TOP design.

```
prompt> align_block_pins -anchor [current_design] -alignee I_DATA_PATH
```

The following example aligns pins from the alignee block to the anchor block and changes the layer and width of the alignee pin to match the layer and width of the connected anchor pin.

```
prompt> align_block_pins -anchor I_DATA_PATH -alignee I_ALU
 -change_layer_width
```

The following example demonstrates how to align off-edge pins between the anchor and alignee blocks.

```
prompt> align_block_pins -anchor I_DATA_PATH -alignee I_ALU -off_edge
```

The following example shows how to customize a prefix 'custom' for the report file.

```
prompt> align_block_pins -anchor I_DATA_PATH -alignee I_ALU
 -report_prefix custom
```

Feedback

align_macros

Aligns macros in the current design.

Syntax

```
status align_macros
[-freeform]
[-max_offset { x_distance y_distance }]
[-max_distance { x_distance y_distance }]
[-macros list_of_macro_cells]
[-group groupbound]
[-reference_macro macro_cell_instance]
[-boundary_threshold { x_distance y_distance }]
[-align_type edge | corner]
[-priority_direction horizontal | vertical]
[-abutment_threshold { x_distance y_distance }]
[-optimize_orientations]
[-channel_size { x_distance y_distance }]
```

Data Types

list_of_macro_cells	collection
groupbound	collection
macro_cell_instance	collection
x_distance	float
y_distance	float

Arguments

`-freeform`

If this option is specified the command in freeform mode, i.e. predominately meant to align the result of freeform macro placement. If the option is not specified, the command is run in floorplan rules mode. The two modes have different sets of options, mutually exclusive.

`-max_offset { x_distance y_distance }`

Specifies maximal offset, i.e. the most each macro can move in each direction. Requires -freeform and -max_distance. If this option is not provided, the command will align very aggressively.

`-max_distance { x_distance y_distance }`

Specifies maximal distance to look for macro to align, i.e. the furthest two macros could be from each other for the command to attempt to align them. Requires -freeform and -max_offset. If this option is not provided, the command will align very aggressively.

Feedback

`-macros` *`list_of_macro_cells`*

Specifies the list of macro cells to align. When provided, the tool will align the provided macros only. This option is mutually exclusive with -group.

`-group` *`groupbound`*

Specifies the macro group (bound) to align. The bound object can be specified by using the *get_bounds* command. However, it must return a collection of one and only one bound object. When provided, the tool will move the macros belonging to that group only. This option is mutually exclusive with -macros. If neither is specified, the tool will align macros of all groups (each group separately), but will not move macros that are not in any group. This option is mutually exclusive with -freeform.

`-reference_macro` *`macro_cell_instance`*

Specifies the reference macro. The object must be a single cell instance. When provided, the tool will use this macro to decide which edges to align to. See -boundary_threshold below for more details. This option is mutually exclusive with -freeform.

`-boundary_threshold { x_distance y_distance }`

Specifies the distance from the edge (in both directions) that will trigger alignement. Generally, when macros are within this distance from a boundary edge, the tool will align to that edge. If macros belong to a voltage area, the boundary is the voltage area shape; otherwise it is the block boundary. However, the tool will only align to a corner or one edge, not to opposite edges. If two adjacent edges are within threshold, the tool will align either to the corner made by the two edges or to one of the edges, as specified by -align_type argument below. If opposite edges are both within this threshold, the tool will align to the one closer to the macros. If this option is not specified, and reference macro is specified, the tool will align macros to the bounding box of the macros, using corner that is the closest to the reference macro. If this option is not specified, and reference macro is also not specified, the tool will align some macros only to each other, there will be no pushing to edges. This option is mutually exclusive with -freeform.

`-align_type` *`edge`* | *`corner`*

Specifies whether to align macros to an edge or a corner. The default is corner. If the value is corner, the tool will align to the corner determined by the two closest edges, assuming both distances are within -boundary_threshold distance. If the value is edge, the tool will align only to the closest edge, assuming it is within -boundary_threshold distance. This option requires -boundary_threshold. This option is mutually exclusive with -freeform.

Feedback

`-priority_direction` *`horizontal | vertical`*

Specifies the direction to align first. When -align_type is corner, there could be both horizontal and vertical aligning to the boundary. The resulting placement of macros will be dependent on which direction is done first. This option allows user to specify which direction to use first. If the option is not specified, the tool will try to automatically infer the better choice. This option is mutually exclusive with -freeform.

`-abutment_threshold { x_distance y_distance }`

Specifies the distance to use when determining whether to abut macros. When this option is specified, the tool will try to abut macro instances of the same lib cell that are within the specified distance of each other. Otherwise, the macros will be spaced using -channel_size option below. The abutment will only happen if the result will be legal with respect to the floorplan rules. Note that the distance will be measured after the command has already aligned the macros, so it may differ from the distance before the command has been run. This option is mutually exclusive with -freeform.

`-optimize_orientations`

Specifies whether to flip macros to achieve better result. Floorplan rules are frequently set in a way that the minimal allowed distance between two macros depends on their orientations. In particular, abutment is only allowed for certain orientation combinations. When this option is specified, the tool will flip the macros in a way that will increase the chance that abutment will be allowed by the floorplan rules. This option requires -abutment_threshold. This option is mutually exclusive with -freeform.

`-channel_size { x_distance y_distance }`

Specifies the preferred channel size between macros. The actual channel size that will be used for a given pair of macros may be larger than preferred channel size in order to make it legal with respect to the floorplan rules. However, if -abutment_threshold option is specified, and if abutment is legal with respect to the floorplan rules, the tool will abut the macros, as abutment is considered higher priority than channel size. If this option is not specified, the tool will consider the values to be 0, i.e. the tool will use the smallest distance allowed by the floorplan rules. This option is mutually exclusive with -freeform.

Description

Performs alignment of macros in the design, and sets the distance between macros with the input from the the chosen options and floorplan rules. Optionally, it also pushes macros towards the edges of the design or the the voltage area they belong to. The macro movement is displayed in gui using annotations; those can be removed using *gui_remove_all_annotations* command.

Feedback

Examples

The following example aligns macros, while making sure that no macro moves further than 25 in x direction, nor further than 15 in y direction. Furthermore, two macros will be aligned vertically only if they are at most 7 apart in y direction; note that aligning vertically means macros are moved horizontally to make the x coordinates of their left or right edges coincide. Similar restriction holds for horiontal alignment - only if macros are at most 5 apart in x direction.

```
prompt> align_macros -freeform -max_offset {25 15} -max_distance {5 7}

The following example performs alignment of macros belonging to bound
 group1 and pushes them
to the closest corner of the design edge.
It also abuts macros if possible when they are close enough to each
 other,
as well as flips macros, if that would make the abutment more likely.

prompt> align_macros -group group1 -align_type corner -priority_direction
 vertical
-boundary_threshold {10 10} -channel_size {2 2} -abutment_threshold {1 1}
 -optimize_orientations
```

The following example aligns macros and pushes them to the corner of the bounding box of the macros. The corner is determined as the one closest to the specified macro RAM1.

```
prompt> align_macros -group group1 -reference_macro [get_cells RAM1]
 -priority_direction horizontal -channel_size {1 1}
```

---

align_objects

Aligns specified objects.

Feedback

Syntax

status *align_objects*

```
[-anchor object_list]
[-parent]
[-to point]
[-to_box box]
[-side alignment_side]
[-anchor_side anchor_side]
[-offset offset]
[-skip_anchor]
[-group]
[-margin]
[-force]
[-simple]
[object_list]
```

Data Types

object_list	collection
point	float
box	list
alignment_side	string
anchor_side	string
offset	float

Arguments

object_list

Collection or selection set containing objects to align. If this option is not specified, the global selection set is used.

-anchor *object_list*

Specifies the objects to which other objects are aligned.

-parent

Aligns objects to the parent edge.

For terminals and I/O pads, the parent object is the die. For soft macro pins, the parent object is the soft macro. For all other objects, the parent is the core.

-to *point*

Specifies a point with which to align the objects.

-to_box *box*

Specifies a box with which to align the objects.

Feedback

`-side` *`alignment_side`*

Specifies the side of the object to be aligned. The valid value is one of *left*, *right*, *hcenter*, *bottom*, *top*, *vcenter*.

The description of the valid values are as follows:

```
left    - align to the left side
right   - align to the right side
top     - align to the top side
bottom  - align to the bottom side
hcenter - align to the horizontal center
vcenter - align to the vertical center
```

The default is *left*.

`-anchor_side` *`anchor_side`*

Specifies the anchor object side to use when aligning objects. Valid values are *auto*, *ll*, *ur*, or *center*.

```
auto    - determine anchor side automatically
ll      - align to the lower-left side of the anchor object
ur      - align to the upper-right side of the anchor object
center  - align to the center of the anchor object
```

The default is auto.

`-offset` *`offset`*

Specifies the offset from the specified anchor object's side. The default is *0.0*.

`-skip_anchor`

When *-offset* is specified and anchor is not given explicitly with -anchor/-parent/-to/-to_box options then this option allows to skip implicit anchor object when applying offset. This option is not compatible with -anchor, -parent, -to or -to_box options and requires -offset option be specified.

`-group`

Treat the objects as a single object. If you specify *-group*, the tool maintains the relative position between the specified objects. Be default, objects are treated individually.

`-margin`

Use extended objects boundaries. When you specify *-margin*, the block boundaries are extended with keepout margins and voltage area boundaries

Feedback

are extended with guard bands. To exclude certain block keepout margins from consideration, use the following command:

```
prompt> win_set_filter -class cell \\
   -filter {hard_macro_margin hard_margin route_blockage_margin
 soft_margin}
```

`-force`

Resizes locked or fixed objects. By default, such objects are not resized according to global edit settings. Edit settings can be accessed using *get_edit_setting*.

`-simple`

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using *get_snap_setting*.

Description

This command aligns a list of unfixed objects so that their left, right, top, or bottom edges are coincident with, or at a specified offset from, an anchor object or anchor position.

You can specify an anchor object or anchor position, or allow the command to automatically determine the anchor object from the supplied list of objects by using the following algorithm:

- If any objects are marked as fixed, the anchor object is selected from the set of fixed objects. The rightmost fixed object is used for right alignment, the topmost fixed object is used for top alignment, and so on.
- If no objects are marked as fixed, then the anchor object is the leftmost, rightmost, topmost, or bottommost object for alignment of left, right, top, and bottom, respectively.

NOTE:Snapping is done automatically using global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example moves the currently selected objects so that their left edges are *20* units from the left edge of the core.

```
prompt> align_objects -parent -offset 20
```

The alternative syntax uses a collection to specify the objects.

```
prompt> align_objects [get_selection] -parent -offset 20
```

Feedback

---

align_pins

Aligns the specified block pins with their connected pins. If no block pins are specified, the command aligns the currently selected block pins.

Syntax

status *align_pins*

```
[object_list]
[-change_layer]
[-change_layer_width]
[-change_layer_height]
[-move_connected]
```

Data Types

object_list collection

Arguments

object_list

Specifies a collection or selection list that contains pins to align. If this option is not specified, the global selection list is used.

-change_layer

Changes the pins' layer to match the layer of the connected pin. This option is mutually exclusive with -change_layer_width and -change_layer_height.

Feedback

`-change_layer_width`

Changes the pins' layer and width to match the layer and width of the connected pin.

`-change_layer_height`

Changes the pins' layer and height to match the layer and width of the connected pin.

`-move_connected`

Uses given set of pins as reference and moves connected pins instead.

Description

This command aligns pins specified in *object_list* or the currently selected pins. Pins are aligned with the pins to which they connect based on the current snapping constraints. For each pin to align, the tool finds another pin that connects to the same net and uses the connected pin as an anchor object. After the command completes, the center points for both the selected pin and the anchor pin should be on the same horizontal or vertical lines if both pins satisfy the current snapping constraints.

Note that the *align_pins* command does not consider side, layer, offset, and other pin constraints specified by the *set_individual_pin_constraints*, *create_block_pin_constraint*, or *read_pin_constraints* commands. To place pins while honoring constraints set by these commands, use the *place_pins* command.

You should only use the *align_pins* command when the connected pins are physically close and have no obstacles between them. This command does not perform overlap checking or blockage avoidance. Alignment is not performed and the pin is not moved if any of the following are true:

- Pins are marked as fixed
- Selected objects are not of type pin, port, or terminal
- Pins belong to a power or ground net
- Pins have multiple terminals that do not intersect

Note that snapping is done automatically based on global snap settings.

Examples

The following example moves the currently selected pins so that the pins align either horizontally or vertically with their connected pins.

```
prompt> align_pins
```

The following example aligns the currently selected pin and changes the layer and width of the selected pin to match the layer and width of the connected pin.

Feedback

```
prompt> align_pins -change_layer_width
```

The following example uses an alternative syntax to specify a collection of objects.

```
prompt> align_pins [get_pins I_ALU/OUT[2]]
```

---

all_clocks

Creates a collection of all clocks in the specified design.

Syntax

collection *all_clocks*

```
[-design design]
[-mode mode]
```

Data Types

```
design      collection
mode        collection
```

Arguments

`-design design`

Specifies the design for which to return the clocks. You can specify only a single design.

If you do not specify this option, the command returns all clocks in the current design.

Feedback

`-mode` *mode*

Specifies the mode for which to return the clocks. You can specify only a single mode.

If you do not specify this option, the command returns all clocks in the current mode.

Description

The *all_clocks* command creates a collection of all clocks in the specifed design. If you did not define any clocks, the empty collection (empty string) is returned.

If you want only certain clocks, use the *get_clocks* command to create a collection of clocks that match a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the *-mode* option.

Examples

The following example applies the *set_propagated_clock* command to all clocks in the design.

```
prompt> set_propagated_clock [all_clocks]
```

See Also

- collections
- create_clock
- get_clocks
- set_propagated_clock

---

all_connected

Creates a collection of objects connected to nets, scalar nets of net_bus, pins, ports or scalar ports of port_bus.

Syntax

collection *all_connected*

```
[-leaf]
[-physical_context]
objects
```

Feedback

Data Types

objects list

Arguments

-leaf

Specifies that only leaf pins are returned for a hierarchical net.

For nonhierarchical nets, there is no difference in output.

-physical_context

Searches physical objects rather than logical objects.

When specified for nets, the command returns physical pins or ports. For pins and ports, the command returns the physical net, which might be in a different hierarchy and connected to the pin through hierarchical pins or ports.

objects

Specifies the objects whose connections are returned. You must specify objects that are nets, net_bus, pins, ports or port_bus.

This is a required argument.

Description

The *all_connected* command creates a collection of objects connected to the specified nets, net_buses, pins, ports or port_buses. The collection can contain nets, ports, pins, or a combination of ports and pins. In the latter case, the ports are first, followed by the pins.

When issued from the command prompt, the *all_connected* command behaves as though the *query_objects* command has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the *shell.common.collection_result_display_limit* variable.

For information about collections and the querying of objects, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example shows all objects connected to the net named CLOCK.

```
prompt> query_objects -verbose [all_connected [get_nets CLOCK]]
{{port CLOCK} {pin U1/CP} {pin U2/CP} {pin U3/CP} {pin U4/CP}}
```

Feedback

The following example shows all objects connected to the net_bus N.

```
prompt> all_connected N
{{P[7]} {P[6]} {P[5]} {P[4]} {P[3]} {P[2]} {P[1]} {P[0]}}
```

- shell.common.collection_result_display_limit

---

all_corners

Creates a collection of all corners in the current design. You can assign these corners to a variable or pass them into another command.

Syntax

collection *all_corners*

```
[-design  design]
```

Data Types

```
design  collection
```

Arguments

`-design` *design*

Name of the top design. The default is the current design.

Description

The *all_corners* command creates a collection of all corners in the current design. If you do not define any corners, a collection containing the default corner is returned.

If you want only certain corners, use *get_corners* to create a collection of corners matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all corners.

Feedback

See Also

- collections
- create_corner
- current_corner
- get_corners

---

all_dft_partitions

Displays all of the partitions that are defined for the current design.

Syntax

list *all_dft_partitions*

Arguments

The *all_dft_partitions* command has no arguments.

Description

The *all_dft_partitions* returns a list of all the partitions defined for the current design.

Examples

The following example displays a list of DFT partitions that were previously defined in the design, together with the default DFT partition:

```
prompt> define_dft_partition P1 -include u1
prompt> define_dft_partition P2 -include {u2 u3}

prompt> all_dft_partition
default_partition P1 P2
```

- define_test_mode
- insert_dft

Feedback

all_exceptions

Creates a collection of all timing exceptions in the current design.

Syntax

collection *all_exceptions*

```
[-design design]
[-mode mode]
```

Data Types

```
design      collection
mode        collection
```

Arguments

`-design design`

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-mode mode`

Specifies the mode for finding objects. If this is not specified, objects will be found in the current mode.

Description

The *all_exceptions* command creates a collection of all timing exceptions in the current scenario. If no timing exceptions exist, the empty string is returned. You can assign these exceptions to a variable or pass them into another command. Timing exceptions are created by *set_false_path*, *set_multicycle_path*, *set_max_delay* or *set_min_delay*.

If you want only certain exceptions, use *get_exceptions* to create a collection of exceptions matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the *-mode* option.

Examples

This example sets the variable allExcepts to a collection of all timing exceptions in the design.

```
prompt> set allExcepts [all_exceptions]
```

Feedback

See Also

- collections
- set_false_path
- set_multicycle_path
- set_max_delay
- set_min_delay
- get_exceptions
- shell.common.collection_result_display_limit

---

all_fanin

Creates a collection of pins, ports, or cells in the fanin of the specified sinks.

Syntax

collection *all_fanin*

```
[-from from_list]
[-through through_list]
-to to_list
[-flat] [-only_cells]
[-quiet]
[-startpoints_only]
[-levels level_count]
[-pin_levels pin_count]
[-step_into_hierarchy]
[-trace_arcs timing | enabled | all]
[-continue_trace pin_types]
```

Data Types

```
from_list     list
through_list  list
to_list       list
level_count   integer
pin_count     integer
pin_types     string
```

Arguments

`-from from_list`

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanin of each object in *to_list* becomes part of the resulting collection only if it is in the fanout cone

Feedback

of at least one object in *from_list*. If a net is specified, the effect is the same as listing all load pins on the net.

`-through` *`through_list`*

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified the fanin of each object in *to_list* is restricted to objects on paths through the pins, ports or nets in *through_list*.

`-to` *`to_list`*

Specifies a list of sink pins, ports, or nets to trace. Each object is a named pin, port, or net or a collection of pins, ports, or nets. The timing fanin of each sink becomes part of the resulting collection. If a net is specified, the effect is the same as listing all driver pins on the net.

This option is required.

`-flat`

Includes objects throughout the design hierarchy in the result. This means that the only non leaf objects in the result are hierarchical sink pins.

If you do not specify this option, the result includes only objects within the same hierarchical level as the current sink.

`-only_cells`

Includes only cells in the timing fanin of the specified sinks in the result and not pins or ports.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-startpoints_only`

Includes only the timing startpoints in the result.

`-levels` *`level_count`*

Stops the traversal when it reaches the specified cell depth, where the counting is performed over the layers of cells of the same distance from the sink. This option cannot be used together with *-pin_levels*.

`-pin_levels` *`pin_count`*

Stops the traversal when it reaches the specified pin depth, where the counting is performed over the layers of pins of the same distance from the sink. This option cannot be used together with *-levels*.

Feedback

`-step_into_hierarchy`

Performs counting as though the design is flat. Although pins inside the hierarchy are not returned, they determine the depth of the related output pins.

If you do not specify this switch, a hierarchical block at the same level of hierarchy as the current sink is considered to be a cell; the input pins are considered a single level away from the related output pins, regardless of what is inside the block.

This option cannot be used with the *-flat* option and only has effect with either the *-levels* or *-pin_levels* option.

`-trace_arcs timing | enabled | all`

Specifies the type of combinational arcs to trace during the traversal.

Allowed values are *timing* (the default), which permits tracing only of valid timing arcs (that is, arcs which are neither disabled nor invalid due to case analysis); *enabled*, which permits the tracing of all enabled arcs and disregards case analysis values; and *all*, which permits the tracing of all combinational arcs regardless of either case analysis or arc disabling.

`-continue_trace` *`pin_types`*

This option permits you to override the default behavior of the traversal which is to stop at all timing startpoints. When used, the traversal is permitted through startpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- *generated_clock_source* - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

Description

The *all_fanin* command creates a collection of objects in the timing fanin of the specified sink pins, ports, or nets in the design. A pin is considered to be in the timing fanin of a sink if there is a timing path through combinational logic from the pin to that sink (see also the *-trace_arcs* option). The fanin stops at the clock pins of registers (sequential cells).

If the current instance in the design is not the top level of hierarchy, only objects within the current instance are returned.

Note: The all_transitive_fanin command is faster because it does not build a timing graph, if the command is in a loop that alternates fanin queries with the netlist editing commands. It is recommended that you use the all_transitive_fanin command when the fanin objects can be found based on connectivity.

Multicorner-Multimode Support

This command works only on the current mode.

Feedback

Examples

This example shows the timing fanin of a port in the design. The fanin includes a register, reg1.

```
prompt> query_objects [all_fanin -to out_1]
{"out_1", "reg1/Q", "reg1/CP"}
```

This example shows the flat mode of *all_fanin*. The sink is an input pin of a hierarchical cell, H1, which is connected to an output pin of another hierarchical cell, H2. H2 contains additional hierarchy and eventually, a leaf cell with two inputs, each of which has a top-level register in its fanin.

```
prompt> query_objects [all_fanin -to H1/a -flat]
{"H1/a", "H2/U1/n1/Z", "H2/U1/n1/A", "H2/U1/n1/B",
 "reg1/Q", "reg2/Q", "reg1/CP", "reg2/CP"}
```

This example shows the timing fanin of an output port that passes through pin u1/z or pin u2/z.

```
prompt> query_objects [all_fanin -to out -through {u1/z u2/z}]
{"out", "u3/z", "u3/a", "u3/b", "u1/z", "u1/a", "u2/z", "u2/z",
 "reg1/q", "reg2/q", "reg1/cp", "reg2/cp"}
```

This example shows the timing fanin of an output port the passes through pin u1/z and pin u3/a.

```
prompt> query_objects [all_fanin -to out -through u1/z -through u3/a]
{"out", "u3/z", "u3/a", "u1/z", "u1/a", "reg1/q", "reg1/cp"}
```

See Also

- all_fanout
- report_transitive_fanin
- current_instance

---

all_fanout

Creates a collection of pins/ports or cells in the fanout of the specified sources.

Syntax

collection *all_fanout*

```
-from from_list
[-through through_list]
[-to to_list]
[-clock_tree]
[-flat]
```

Feedback

```
[-quiet]
[-only_cells]
[-endpoints_only]
[-levels level_count]
[-pin_levels pin_count]
[-trace_arcs arc_types]
[-step_into_hierarchy]
[-continue_trace pin_types]
```

Data Types

```
from_list       list
through_list      list
to_list           list
level_count      integer
pin_count        integer
arc_types        string
pin_types         string
```

Arguments

`-from from_list`

Specifies a list of source pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each source in *from_list* becomes part of the resulting collection. If a net is specified, the effect is the same as listing all load pins on the net. This option is exclusive with the *-clock_tree* option.

`-through through_list`

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. If a *through_list* is specified the fanout of each object in *from_list* is restricted to pins on paths through the pins, ports or nets in *through_list*.

`-to to_list`

Specifies a list of pins, ports, or nets in the design. Each object is a named pin, port, or net, or a collection of pins, ports, or nets. The timing fanout of each object in *from_list* becomes part of the resulting collection if it is in the fanin cone of at least one object in *to_list*. If a net is specified, the effect is the same as listing all driver pins on the net.

`-clock_tree`

Indicates that all clock source pins or ports in the design are to be used as the list of sources. Clock sources are specified using *create_clock*. If there are no clocks, or if the clocks have no sources, the result is the empty collection. This option is exclusive with the *-from* option.

Feedback

`-flat`

There are two major modes in which *all_fanout* functions: hierarchical (the default) and flat. When in hierarchical mode, only objects within the same hierarchical level as the current source are included in the result. In flat mode, the only non leaf objects in the result are hierarchical source pins.

`-quiet`

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

`-only_cells`

The result includes only cells in the timing fanout of the *from_list* and not pins or ports.

`-endpoints_only`

When this option is specified, only the timing endpoints are included in the result.

`-levels` *`level_count`*

The traversal stops when it reaches a depth of search of *cell_count* hops, where the counting is performed over the layers of cells of same distance from the source. This option cannot be used together with *-pin_levels*.

`-pin_levels` *`pin_count`*

The traversal stops when it reaches a depth of search of *pin_count* hops, where the counting is performed over the layers of pins of same distance from the source. This option cannot be used together with *-levels*.

`-trace_arcs` *`arc_types`*

Specifies the type of combinational arcs to trace during the traversal. Allowed values are *timing* (the default), which permits tracing only of valid timing arcs (that is, arcs which are neither disabled nor invalid due to case analysis); *enabled*, which permits the tracing of all enabled arcs and disregards case analysis values; and *all*, which permits the tracing of all combinational arcs regardless of either case analysis or arc disabling.

`-step_into_hierarchy`

This option might only be used in hierarchical mode and only has effect with either *-levels* or *-pin_levels*. Without the switch, a hierarchical block at the same level of hierarchy as the current sink is considered to be a cell; the output pins are considered a single level away from the related input pins, regardless of what is inside the block. With the switch enabled, the counting is performed as though the design were flat, and although pins inside the hierarchy are not returned, they determine the depth of the related input pins.

Feedback

`-continue_trace` *`pin_types`*

This option permits you to override the default behavior of the traversal which is to stop at all timing endpoints. When used, the travsal is permitted through endpoint pins of a type specified with *pin_types*. Allowed *pin_types* are:

- *generated_clock_source* - Specifies that the traversal is to continue tracing through source pins of generated clocks including sequential clock pins in the generated clock source network.

Description

The *all_fanout* command creates a collection of objects in the timing fanout of specified source pins/ports or nets in the design. A pin is considered to be in the timing fanout of a source if there is a timing path through combinational logic from that source to the pin (also see the *-trace_arcs* option). The fanout stops at the inputs to registers (sequential cells). The sources are specified using either *-clock_tree* or *-from from_list*.

If current instance in the design is not the top level of hierarchy, only objects within the current instance are returned.

Note: The all_transitive_fanin command is faster because it does not build a timing graph, if the command is in a loop that alternates fanin queries with the netlist editing commands. It is recommended that you use the all_transitive_fanin command when the fanin objects can be found based on connectivity.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

This example shows the timing fanout of a port in the design. The fanout includes a register, reg3.

```
prompt> query_objects [all_fanout -from in1]
{"in1", "reg3/D"}
```

This example shows the difference between the hierarchical and flat modes of *all_fanout*. The source is an output pin of a hierarchical cell, H3/z1, which is connected to an input pin of another hierarchical cell, H4/a. H4 contains a leaf cell U1 with input A and output Z. The first command is hierarchical mode, and shows that hierarchical pins are included in the result. The second command is in leaf mode, and leaf pins from the lower level are included.

```
prompt> query_objects [all_fanout -from H3/z1]
{"H3/z1", "H4/a", "H4/z", "reg2/D"}

prompt> query_objects [all_fanout -from H3/z1 -flat]
{"H3/z1", "H4/U1/A", "H4/U1/Z", "reg2/D"}
```

Feedback

This example shows how to get the fanout of reg1/CP on paths passing through u1/Z and U3/Z.

```
prompt> query_objects [all_fanout -from reg1/CP -through U1/Z \\
          -through U3/A]
{"out", "U3/Z", "U3/A", "U1/Z", "U1/A", "reg1/Q", "reg1/CP"}
```

See Also

- all_fanin
- current_instance
- report_transitive_fanin

---

all_high_transitive_fanout

Returns a collection of high-fanout nets from the current design or from the specified input collection. A tie net will be filtered out in the collection.

Syntax

collection *all_high_transitive_fanout*

```
-nets
[-threshold value]
[input_coll]
[-through_buf_inv]
```

Data Types

```
value          float
input_coll     collection
```

Arguments

`-nets`

Returns the collection of high-fanout nets.

`-threshold value`

Specifies a threshold value used to determine if a net is a high-fanout net. The *value* is a user-specified value. If the value is less than 1, a default value will be the threshold. By default, the value of the *design.high_fanout_net_threshold* application option is used to determine if a net is a high-fanout net.

input_coll

Searches the specified input collection for high-fanout nets. Objects are to be searched only from the contents of the specified input collection, rather than from the design.

Feedback

`-through_buf_inv`

Indicates to treat a buffer tree as transparent. The leaf loads of the buffer tree are treated as the fanouts of the net.

Description

The *all_high_transitive_fanout* command returns a collection of all high-fanout nets in the design. The tool searches the entire design hierarchy. It returns nets from the entire design, not just from the top level.

To determine if a net is a high-fanout net, use the *design.high_fanout_net_threshold* option value as the threshold value. The command returns all nets with a fanout count not less than this threshold as high-fanout nets. You can also specify the threshold by using the *-threshold* option.

If you specify a value for *input_coll*, the command searches for high-fanout objects only from the specified collection, rather than from the entire design.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as *foreach_in_collection*, *sizeof_collection*, and so on, can be performed on this collection handle.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows the collection of all high-fanout nets from the design:

```
prompt> all_high_transitive_fanout -nets
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from an existing collection stored in $COLL:

```
prompt> all_high_transitive_fanout -nets $COLL
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from the design having a fanout count of more than 100:

```
prompt> all_high_transitive_fanout -nets -threshold 100
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

See Also

- all_transitive_fanin
- all_transitive_fanout

Feedback

- foreach_in_collection
- sizeof_collection

---

all_inputs

Creates a collection of all input ports in the current design. You can assign these ports to a variable or pass them into another command.

Syntax

collection *all_inputs*

```
[-level_sensitive]
[-exclude_clock_ports]
[-edge_triggered]
[-clock clock_name]
```

Data Types

```
clock_name        list
```

Arguments

`-level_sensitive`

Only considers ports with level-sensitive input delay. This is specified by *set_input_delay 2 -clock CLK -level_sensitive IN1*. This option cannot be used together with *-edge_triggered*.

`-exclude_clock_ports`

Excludes input ports which serve as clock sources.

`-edge_triggered`

Only considers ports with edge-triggered input delay. This is specified by *set_input_delay 2 -clock CLK IN2*. This option cannot be used together with *-level_sensitive*.

`-clock clock_name`

Only considers ports with input delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

Description

The *all_inputs* command creates a collection of all input or inout ports in the current design. You can limit the contents of the collection by specifying the type of input delay that must be on a port.

Feedback

You can remove clock source ports from the resulting collection by specifying *-exclude_clock_ports* option.

If you want only certain ports, use *get_ports* to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, *all_inputs* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable *collection_result_display_limit*.

For information about collections and the querying of objects, see the *collections* man page.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example specifies a driving cell for all input ports.

```
prompt> set_driving_cell -lib_cell FFD3 -pin Q [all_inputs]
```

See Also

- collections
- get_ports
- query_objects
- report_ports
- set_driving_cell
- set_input_delay
- shell.common.collection_result_display_limit

---

all_modes

Creates a collection of all modes in the current design. You can assign these modes to a variable or pass them into another command.

Syntax

collection *all_modes* [-design *design_name*]

Feedback

Data Types

design_name string

Arguments

`-design` *design_name*

Name of the top design. The default is the current design.

Description

The *all_modes* command creates a collection of all modes in the current design. If you do not define any modes, a collection containing the default mode is returned.

If you want only certain modes, use *get_modes* to create a collection of modes matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all modes.

Examples

This script uses the *all_modes* command to perform *report_clocks* one time for each defined mode.

```
foreach_in_collection mode [all_modes] {
  current_mode $mode
  report_clocks
}
```

See Also

- collections
- create_mode
- current_mode
- get_modes
- report_clocks

---

all_outputs

Creates a collection of all output ports in the current design. You can assign these ports to a variable or pass them into another command.

Syntax

collection *all_outputs*

Feedback

```
[-level_sensitive]
[-edge_triggered]
[-clock clock_name]
```

Data Types

```
clock_name      list
```

Arguments

`-level_sensitive`

Only considers ports with level-sensitive output delay. This is specified by *set_output_delay 2 -clock CLK -level_sensitive IN1*. This option cannot be used together with *-edge_triggered*.

`-edge_triggered`

Only considers ports with edge-triggered output delay. This is specified by *set_output_delay 2 -clock CLK IN2*. This option cannot be used together with *-level_sensitive*.

`-clock clock_name`

Only considers ports with output delay relative to a specific clock. This can be the name of a clock, or a collection containing a clock.

Description

The *all_outputs* command creates a collection of all output or inout ports in the current design. You can limit the contents of the collection by specifying the type of output delay that must be on a port.

If you want only certain ports, use *get_ports* to create a collection of ports matching a specific pattern and optionally passing filter criteria.

When issued from the command prompt, *all_outputs* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed; you can change this maximum using the variable *collection_result_display_limit*.

For information about collections and the querying of objects, see the *collections* man page.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example specifies a pin capacitance for all output ports.

```
prompt> set_load 4.56 [all_outputs]
```

Feedback

The following example shows the names all of the output ports with output delay relative to PHI1.

```
prompt> all_outputs -clock PHI1
```

See Also

- collections
- get_ports
- report_ports
- query_objects
- set_output_delay
- shell.common.collection_result_display_limit

---

all_registers

Creates a collection of register cells or pins. You can assign the resulting collection to a variable or pass it into another command.

Syntax

collection *all_registers*

```
[-clock clock_name]
[-rise_clock rise_clock_name]
[-fall_clock fall_clock_name]
[-cells]
[-data_pins]
[-clock_pins]
[-async_pins]
[-output_pins]
[-level_sensitive]
[-edge_triggered]
```

Data Types

```
clock_name      list
rise_clock_name list
fall_clock_name list
```

Arguments

`-clock clock_name`

Considers all registers clocked by *clock_name*. This is either the name of a clock or a collection containing a clock. For example, all registers whose clock pins are in the fan out of the specified clock.

Feedback

`-rise_clock` *`rise_clock_name`*

Considers all registers clocked by *rise_clock_name* and having open edge effectively the rising clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops without any inversion on the clock path or falling edge triggered flip-flops with inversion on the clock path.

`-fall_clock` *`fall_clock_name`*

Considers all registers clocked by *fall_clock_name* and having open edge effectively falling the clock edge. This is either the name of a clock, or a collection containing a clock. For example, rising edge triggered flip-flops with inversion on the clock path or falling edge triggered flip-flops without any inversion on the clock path.

`-cells`

Creates a collection of cells (default). The cells are registers and are further limited by other command options.

`-data_pins`

Creates a collection of register data pins. The collection can be limited by other command options.

`-clock_pins`

Creates a collection of register clock pins. The collection can be limited by other command options.

`-async_pins`

Creates a collection of asynchronous preset or clear pins.

`-output_pins`

Creates a collection of register output pins.

`-level_sensitive`

Limits search to level-sensitive latches.

`-edge_triggered`

Limits search to edge-triggered flip-flops.

Description

The *all_registers* command creates a collection of pins or cells related to registers.

When issued from the command prompt, *all_registers* behaves as though *query_objects* had been called to display the objects in the collection. By default, a maximum

Feedback

of 100 objects is displayed. You can change this maximum using the variable *collection_result_display_limit*.

For information about collections and the querying of objects, see the *collections* man page.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following command returns all registers in the current design.

```
prompt> all_registers
```

---

all_scenarios

Creates a collection of all scenarios in the current design.

Syntax

collection *all_scenarios*

```
[-design design]
```

Data Types

```
design      collection
```

Arguments

```
-design design
```

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

Description

The *all_scenarios* command creates a collection of all scenarios in the current design, or the design specified by the *-design* option.

Feedback

If you want only certain scenarios, use *get_scenarios* to create a collection of scenarios matching a specific pattern and optionally pass in filter criteria.

Multicorner-Multimode Support

This command works on all scenarios.

See Also

- collections
- report_scenarios
- create_scenario
- current_scenario
- get_scenarios

---

all_test_modes

Displays all of the test modes that are defined for the current design.

Syntax

list *all_test_modes*

Arguments

The *all_test_modes* command has no arguments.

Description

The *all_test_modes* returns a list of all the modes defined for the current design. The *define_test_mode* command is used to define a test mode of operation for a design.

Examples

The following is an example of the test modes report:

```
set mode_list [all_test_modes]
foreach m $mode_list {
  current_test_mode $m
  dft_drc
}
```

See Also

- list_test_modes
- current_design

Feedback

- current_test_mode
- define_test_mode
- insert_dft

---

all_thermal_scenario

List all thermal scenario.

Syntax

status *all_thermal_scenario*

Description

List all thermal scenario.

Examples

The following example shows the usage:

```
prompt> all_thermal_scenario
```

See Also

Feedback

all_transitive_fanin

Reports pins, ports, or cells in the fanin of specified sinks.

Syntax

list *all_transitive_fanin*

```
-to sink_list
[-startpoints_only]
[-only_cells]
[-flat]
[-levels count]
```

Data Types

```
sink_list     list
count         int
```

Arguments

`-to sink_list`

Reports a list of sink pins, ports, or nets in the design and connectivity based fanin of each sink in the *sink_list*. If you specify a net, the effect is the same as listing all driver pins on the net.

`-startpoints_only`

Returns only the connectivity startpoints.

`-only_cells`

Results in a set of all the cells in the connectivity fanin of the *sink_list*.

`-flat`

Specifies to function in the flat mode of operation. The two major modes in which *all_transitive_fanin* functions are hierarchical (default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current sink are returned. Thus, pins within a level of hierarchy lower than that of the sink are used for traversal but they will not be reported.

`-levels count`

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are of equidistant from the sink.

Description

This command reports the connectivity fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the connectivity fanin of a sink if there is a path

Feedback

through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells).

NOTE: This command reports results except the cases 1. *false paths* do not have an impact on this commands ability to trace logic 2. manually created clocks are not treated as paths start points

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following examples show the connectivity fanin of a port in the design. The design comprises three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_transitive_fanin -to tout
{"ii2/hin", "iv3/in", "iv3/out", "tin", "ii2/hout", "tout"}

prompt>  all_transitive_fanin -to tout -flat

{"ii2/iv1/U1/a", "ii2/iv2/U1/z", "tin", "iv3/U1/a", "ii2/iv1/U1/z",
"ii2/iv2/U1/a", "iv3/U1/z", "tout"}
```

See Also

- all_transitive_fanout
- all_fanin
- all_fanout
- report_transitive_fanin

---

all_transitive_fanout

Returns a set of pins, ports, or cells in the fanout of the specified sources.

Syntax

list *all_transitive_fanout*

```
-from source_list
[-endpoints_only]
[-only_cells]
[-flat]
[-levels count]
```

Feedback

Data Types

source_list	list
count	int

Arguments

`-from` *source_list*

Specifies a list of source pins, ports, or nets in the design. The connectivity fanout of each source in *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net.

`-endpoints_only`

Returns only connectivity endpoints as a result.

`-only_cells`

Results in a set of all cells in the connectivity fanout of the *source_list*, rather than a set of pins or ports.

`-flat`

Specifies to function in the flat mode of operation. The two major modes in which *all_transitive_fanout* functions are hierarchical (default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current source are returned. Thus, pins within a level of hierarchy lower than that of the source are used for traversal but are not reported.

`-levels` *count*

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are of equidistant from the source.

Description

This command reports the connectivity fanout of specified source pins, ports, or nets in the design. A pin is considered to be in the connectivity fanout of a sink if there is a path through combinational logic from that source to the pin. The fanout report stops at the inputs to registers (sequential cells).

NOTE: This command reports results except the cases

1.*false paths* do not have an impact on this commands ability to trace logic 2.Manually created clocks are not treated as paths start points

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example shows the connectivity fanout of a port in the design. The design comprises three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_transitive_fanout -from tin
{"iv3/out", "tout", "iv3/in", "ii2/hin", "ii2/hout", "tin"}

prompt> all_transitive_fanout -from tin -flat
{"tout", "ii2/iv2/U1/z", "ii2/iv1/U1/a", "iv3/U1/z", "iv3/U1/a",
"ii2/iv2/U1/a", "ii2/iv1/U1/z", "tin"}

prompt> all_transitive_fanout -from tin -levels 1 -only_cells
{"iv3", "ii2"}
```

---

analyze

Analyzes the specified HDL source files and stores the resulting templates into the specified library in a format ready to specialize and elaborate to form linkable cells of a full design.

Syntax

status *analyze*

```
[-format verilog | sverilog | vhdl]
[-standard 1987 | 1993 | 1995 | 2001 | 2005 | 2008 | 2009 | 2012]
[-define define_list]
[-hdl_library hdl_library_name]
[-uses design_libs_list]
[-vcs vcs_opts]
[-update]
[-recursive]
[-autoread]
[-rebuild]
[-output_script output_string]
[-exclude exclude_list]
[-verbose]
[-top top_design_name]
file_list
```

Feedback

Data Types

```
file_list          list
hdl_library_name   string
design_libs_list   string
define_list        string
vcs_opts           string
output_string      string
top_design_name string
exclude_list       list
```

Arguments

`-hdl_library` *`hdl_library_name`*

Specifies the template library where analyzed output files are stored. When the -hdl_library option is not used, the hdl_library_name is taken from *hdlin.hdl_library.default_name*. If the directory for the hdl_library_name is not defined, then *define_hdl_library* is automatically called to do so.

`-uses` *`design_libs_list`*

This option is not available with the *-format vhdl* or *-autoread* option.

SystemVerilog and Verilog designs might contain unresolved references to unelaborated design templates without indication of where those template definitions are located.

The compiler and linker always search for these templates first in the home directory of the parent design. By default, they then continue each template search by visiting every design library defined by the *define_hdl_library* command. The *-uses* option overrides this last step. It stores a design library search order within each design being analyzed. Later, elaboration or linking will follow this prescribed order rather than visiting every known library. An empty list argument limits the search to just the home library of the parent design. You do not need to repeat the *-hdl_library* setting, and you cannot override a search of the work directory.

`-standard 1987 | 1993 | 1995 | 2001 | 2005 | 2008 | 2009 | 2012`

Specifies the revision year of the IEEE standard that governs the selected language's syntax and semantics. The default revision years are IEEE Std 1076-2008 for VHDL, IEEE Std 1800-2012 for SystemVerilog, and IEEE Std 1364-2005 for Verilog.

`-format verilog | sverilog | vhdl`

Specifies the format of the files to be analyzed. The supported formats are Verilog, SystemVerilog, and VHDL.

Feedback

Specifies that the *-autoread* option should look for files in the specified language whose extensions match the extensions in the list identified by the *hdlin.autoread.verilog_extensions*, *hdlin.autoread.sverilog_extensions*, or *hdlin.autoread.vhdl_extensions* application option. The *-autoread* option supports Verilog, SystemVerilog, and VHDL formats. By default, *-autoread* reads in all the files it finds that have Verilog, SystemVerilog, and VHDL extensions. You can use the *-autoread* option to specify file names in the *file_list* that do not have one of the language-specific extensions.

`-vcs` *`vcs_opts`*

Specifies all VCS-specific command-line options. The options must be specified as a single string, such as enclosed within braces ({}) or double quotation marks (""). Options specified by the *-vcs* option follow the VCS command-line syntax:

[-sverilog | -verilog] Specifies the format of the files to be analyzed.

[-y *directory_path*] Specifies the directories that contain the library files to be searched for unresolved module instantiations in the design.

[+libext+.*extension1*+...] Specifies the extension to consider during a file search in the -y library directories. The default is no extension.

[-v *library_file*] Holds several module definitions to be used during the search for unresolved modules.

[-f *command_file*] Specifies a command file.

[-F *command_file*] Specifies a command file, while adding its path prefix to the content of the file list.

[+define+*macro_name*+...] Defines a macro.

[+incdir+*dir1*+...] Includes directories in the search list.

[-libmap *libmap_file*] Specifies a libmap file library declaration.

src_file1 Specifies the files that are to be analyzed.

This option is not available with the *-autoread* option.

`-define` *`defines_list`*

Specifies a list of constant macros to be defined for the session of the *analyze* command. This is useful for the inclusion of Verilog or SystemVerilog code enclosed by `ifdef/`endif constructs. For details, see the documentation.

`file_list`

Specifies the files to be analyzed.

Feedback

To analyze multiple files, list them by using curly braces, {}. Note: Source files in a list are effectively concatenated into a single source stream in the listed order.

In *-autoread* mode only, the *file_list* argument can also specify directory names. All HDL source files located in those directories are prescanned. For more information about prescanning, see the descriptions for the *-autoread* and *-recursive* options.

`-autoread`

Specifies to use the *-autoread* mode for script-free analysis of whole HDL source directories or directory trees. All HDL source files located in those directories are prescanned, grouped, and then ordered into distinct source code streams based on their mutual inclusion and package-reference dependences. Some or all source streams are finally analyzed using the basic command.

This option is being deprecated and is scheduled for removal in a future release.

By default, the *-autoread* option creates or replaces only a subset of analyzed result files; it works in an incremental-update mode that resembles the Unix make command. If an HDL source file does not exist or is newer than the intermediate files it should produce, only that file and the source streams that require it are reanalyzed.

For more information, see the description for the *-rebuild* option.

`-top` *`design_name`*

Identifies the top-level component of a hierarchical design specified within the *-autoread* HDL source directories.

The *analyze -autoread -top design name* command selects a subset of the indicated HDL source streams to analyze. Its goal is to analyze into intermediate form precisely those source files required for a later elaboration and linking of *design_name*. Files in the indicated directories that are not required to elaborate the design hierarchy descending from *design_name* are prescanned but the design templates they would produce are not created or replaced.

If the *-top* option is not provided, all HDL source streams indicated by the *file_list* argument are analyzed.

This option can be used only with the *-autoread* option.

`-recursive`

Specifies that the *analyze -autoread* command must recursively scan the directory trees below those specified in the *file_list* list. By default, the *-autoread* option looks only in the specified directories.

This option can be used only with the *-autoread* option.

Feedback

`-exclude` *`exclude_list`*

Specifies a list of files and directories that are not to be analyzed. An *analyze -autoread [...] file_list* command checks each HDL source path against all elements of the *exclude_list*; it ignores a file if it or any of its directory paths matches any excluded path.

This option can be used only with the *-autoread* option.

`-rebuild`

Replaces any result files regardless of their timestamp. It analyzes all the indicated HDL source streams as if the result library was empty.

This option can be used only with the *-autoread* option.

`-verbose`

Prints out more messages for the *-autoread* option.

This option can be used only with the *-autoread* option.

`-output_script` *`file_name`*

Creates a Tcl script that is compatible with Design Compiler, Fusion Compiler, and Formality.

The file reading order for third-party tools and a DOT language file dependency graph are embedded in the script as comments.

This option is available only with the *-autoread* option.

Description

This command translates the specified HDL files and stores the intermediate format in the specified hdl_library.

The following paragraphs describe the support for the *-autoread* option:

The *-autoread* option reads in the files from file_list, determines the dependencies between them, and analyzes them in the right order to prevent errors due to missed or misplaced files.

The dependencies are calculated only from the files or directories present in *file_list*. If *file_list* changes between consecutive calls with the *-autoread* option, the dependency inference is performed over the latest set of files provided. Based on this, all required sources must be present in *file_list* option or be available if the *-recursive* option is used on each call with the *-autoread* option.

If the top design name is provided by the *-top* option, only the source files required for elaborating that top design are analyzed. This filtering is based on file dependencies

Feedback

previously inferred. If the *-top* option is not provided, all sources are ordered, grouped, and analyzed per the dependency inferred between them.

To locate the source files, the command expands each item in the *file_list* list with the *search_path* variable. Then, it determines whether the result is excluded by the *-exclude* option or the *hdlin.autoread.exclude_extensions* application option. If it is not excluded and a file ends with one of the extensions in the *hdlin.autoread.vhdl_extensions* application option list, it is considered a VHDL source file. If the file ends with one of the extensions in the *hdlin.autoread.verilog_extensions* application option list, it is considered a Verilog source file. If the file ends with one of the extensions in the *hdlin.autoread.sverilog_extensions* application option list, it is considered a SystemVerilog source file.

When expanding a directory, the command collects the files from the directory, and from its subdirectories and theirs recursively if the *-recursive* option is set. The command then performs all extension checks on these files. If the *-format* option is set, only files with Verilog, SystemVerilog, or VHDL extensions are collected based on the value of the option.

After the *-autoread* option collects all of the source files, it performs the following dependency checks:

- Detects analyze dependencies: List RTL files in the right order for analyzing. For example, analyze the file that contains a VHDL entity before analyzing files that defines architectures of that entity, or analyze the file that contains a SystemVerilog package declaration before the files that import that package.
- Detects Verilog and SystemVerilog compilation unit dependencies: Determine if a file needs to be analyzed in the same compilation unit with other files. For example, if a file defines macros, SystemVerilog local parameter, and SystemVerilog enumerated values, and the file is not explicitly included by the file that requires that definitions, the *-autoread* option groups them in the same compilation unit in the correct order. This might not always be possible, such as when a macro is defined several times in different files and the *-autoread* option cannot determine which of those alternatives is the right choice.
- Detects link dependencies: Schedule the analyze stage for files required for elaboration of the design hierarchy. For example, if a Verilog or SystemVerilog design that is instantiated in one source file is declared on a different source file provided in the *file_list*, the second file also requires to be analyzed for a complete top-down design elaboration.
- Detects include dependencies: If a Verilog or SystemVerilog file is included in another source and the file changes between two consecutive calls of the *-autoread* option (in

Feedback

the same synthesis session), the *analyze* command includes this file and all files that include them to update the design.

- Infers the target library for VHDL files. However, if the *-library* option is specified, this step is skipped and VHDL files provided in the *file_list* are analyzed into the specified design library.

After the dependency check, all the required HDL files specified by the *file_list* option (regarding its dependencies and the *-top design* option if defined) are analyzed.

When the *-autoread* option is used again (with the same *file_list* setting) after a file is changed, only the updated source files are analyzed.

The *-autoread* option executes the dependency analysis based only on the current *file_list* information. All HDL source files that might have relevant dependency relationships should be passed together in one *analyze -autoread* command.

Examples

The following example analyzes the packages.vhd file and stores the results in the MY_LIB HDL library:

```
prompt> analyze -format vhdl -hdl_library my_lib packages.vhd
```

The following example specifies a list of constant macros to be defined for the session of the analyze command, consider the given RTL:

```
// test.v
  `define VALB 4
  `define VALA 6
  module test (output [3:0] b) ;
  assign b=`VALB + `VALA + `VALC;
  endmodule
```

- If tool does not find the definition of any macro either in RTL or from *analyze* command, tool issues *VER-913* error. For example, issuing only “analyze -format sverilog test.v” generates the following error.

```
        Error:  ./test.sv:4: The macro 'VALC' has not been defined.
 (VER-913)
```

- By default, the analyze command macro defines override the RTL values. You would get *VER-1051* message when tool detects that there are *analyze* command overwrites for any RTL defined macros.

Default behavior when macros are overwritten from *analyze* command

```
promt> analyze -define "VALB=7 VALA=2 VALC=4" -format sverilog test.v
promt> elaborate test
```

Feedback

```
promt> set_top_module test
promt> write -format verilog -hier -output 2.v

# 2.v netlist
 assign b[3] = 1'b1 ;
 assign b[2] = 1'b1 ;
 assign b[1] = 1'b0 ;
 assign b[0] = 1'b1 ;
```

- Set hdlin.analyze_prioritize_command_line_defines to false to prioritize RTL macro values instead, the example takes VALA and VALB from RTL based on the app option and the VALC from the -define list. Tool would print *VER-403* and *VER-540* messages in that case alerting you about possible conflict in the macro value specifications.

```
promt> set_app_options -name
 hdlin.analyze_prioritize_command_line_defines -value false
promt> analyze -define "VALB=7 VALA=2 VALC=4" -format sverilog test.v
promt> elaborate test
promt> set_top_module test
promt> write -format verilog -hier -output 3.v

        # 3.v  netlist
 assign b[3] = 1'b1 ;
 assign b[2] = 1'b1 ;
 assign b[1] = 1'b1 ;
 assign b[0] = 1'b0 ;
```

The following example analyzes two SystemVerilog clients of two libraries:

```
prompt> define_hdl_library BUSDEFN -path /remote/IP/metra/big_bus
prompt> define_hdl_library NClib   -path ../../NCD/libNC
prompt> analyze -format sverilog -uses { BUSDEFN  NClib }
 { senderAlice.sv receiverBob.sv }
```

The following example assumes that the current directory is the source directory. It specifies the source file list early in the command line and gives options, including the name of the top-level entity later.

```
prompt> analyze {.} -autoread -recursive -top E1
```

The next example specifies extensions for Verilog files that are different from the default ({.v}), sets the source list and the exclude list, and calls the command with the name of the top-level module name, forcing it to only collect files with Verilog extensions:

```
prompt> set_app_options -name hdlin.autoread.sverilog_extensions -value
 {.ve .VE}
prompt> set my_sources {mod1/src mod2/src}
prompt> set my_excludes {mod1/src/incl mod2/src/incl}
prompt> analyze $my_sources -exclude $my_excludes -autoread \\
   -format verilog
```

Feedback

Note that excluding include directories explicitly is only necessary if include files have the same extensions as source files and not all include files are included in the source.

---

analyze_datapath_extraction

Analyzes DesignWare datapath extraction.

Syntax

status *analyze_datapath_extraction*

```
[-html_file file]
[-max_msgs max_num_msgs]
[-no_autoungroup]
[-no_report]
[-nosplit]
[module_list]
```

Arguments

`-html_file` *`file`*

Redirect the output of the report to specified files in HTML format.

`-max_msgs` *`max_num_msgs`*

Specifies the maximum number of messages of each type to display in each module.

`-no_autoungroup`

Specifies that automatic ungrouping is disabled. All hierarchies are preserved unless otherwise specified. The *-no_autoungroup* option in *analyze_datapath_extraction* behaves the same way as the *-no_autoungroup* option in *compile*. If you plan to specify the *-no_autoungroup* option in *compile*, you should also specify the *-no_autoungroup* option in *analyze_datapath_extraction*.

Feedback

`-no_report`

Specifies not to report contained resources at the end of the analysis.

`-nosplit`

Does not split lines if column overflows.

`module_list`

Specifies list of modules to run datapath extraction analysis. If it's not specified, the whole current design will be analyzed.

Description

This command analyzes the datapath extraction of the current design.

When a DesignWare operator is not extracted, it analyzes the reason why it is not extracted. If it is due to the RTL coding, the tool issues a message about the RTL coding style that interferes with datapath extraction.

After the analysis, a report shows the contained resources in the design. This report helps to find the resources in the design source code.

The messages are sorted based on the priority. From high to low, the message types are "HDL-120", "HDL_132", "HDL-129", "HDL-133", "HDL-122", "HDL-125", "HDL-126", and "HDL-121". Within the same type, the messages are also sorted based on their potential impact.

For big designs, there could be a large number of messages. To make the output more readable, besides the *-max_msgs* option, the *set_msg* command can also be used in advance to control the desired number of each message in total to show, or just filter out some of the messages.

For more information about RTL coding styles that help improve datapath extraction, see the coding guidelines documented in "Coding Guidelines for Datapath Synthesis" on SolvNet (https://solvnet.synopsys.com/retrieve/015771.html).

Here are examples of possible warning messages issued by the *analyze_datapath_extraction* command:

"HDL-120": Issued when a DesignWare operator is breaking the datapath due to leakage on its fanout or the fanout of its driver. This DesignWare operator can be the boundary node of an extracted datapath block.

Datapath leakage occurs when an internal operand is not wide enough to store the result of an operation but the full result is required later. Operands with leakage must be binary and must be at the boundary of a datapath block. Therefore, operands with leakage will break a potentially larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

Feedback

Example 1: module test(a, b, c, d, e, f, o1, o2, o3); input [10:0] a, b; input [5:0] c, d, e, f; output [8:0] o1; output [9:0] o2; output [7:0] o3; assign o1 = a + b + c; (add_9, add_9_2) assign o2 = f + o1; (add_10) assign o3 = e + o1; (add_11) endmodule

In this design, the input 'o1' of 'add_10' is truncated. Therefore, the following message is issued:

Information: Operator associated with resources 'add_10' in design 'test' breaks the datapath extraction because there is leakage due to truncation on the fanout of its driver 'add_9 add_9_2'. (HDL-120)

On the other hand, the width of 'o3' is smaller than the width of 'o1'. Therefore, there is no leakage on the input of 'add_11".

Example 2: module leakage_a (a, b, c, z); input signed [7:0] a, b; input [7:0] c; output [9:0] z; wire signed [8:0] t; assign t = a + b; //add_6 // leakage: signed result used in wider unsigned expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(signed) and fanout(unsigned) of add_6:

Information: Operator associated with resources 'add_6' in design 'leakage_a' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Example 3: module leakage_b (a, b, c, z); input [7:0] a, b; input signed [7:0] c; output signed [10:0] z; wire signed [8:0] t;

assign t = a + b; // add_7 // leakage: unsigned result used in wider signed expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(unsigned) and fanout(signed) of add_7:

Information: Operator associated with resources 'add_7' in design 'leakage_b' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Subtraction can give negative results that cannot be represented with an unsigned operand of limited width. It is recommended to declare the operands as signed. Note that constants used in signed operations need to be marked signed as well.

Example 4: It is recommended to change the following RTL code: input [13:0] a ; input [13:0] b ; wire [15:0] o = a - 14'd4 - b ;

to

input signed [13:0] a ; input signed [13:0] b ; wire signed [15:0] o = a - 14'sd4 - b;

The "HDL-120" message is associated with coding guideline 19. (https://solvnet.synopsys.com/retrieve/015771.html#leakage).

"HDL-121": There is a sequential cell that breaks the datapath extraction.

Feedback

Example: module test (clk, en, a, b, c, z); input clk, en; input [7:0] a, b; input [15:0] c; output [15:0] z; reg [15:0] prod;

always @ (posedge clk) begin if (en) begin prod <= a * b; end end assign z = prod + c; endmodule

There is a register between the multiplier and the adder. The following message will be issued:

Information: There is sequential cell in between operator associated with 'mult_11' and 'add_15' in design 'test'. (HDL-121)

The extracted datapath block cannot contain sequential cells (for example, registers). The register in between operators will break a potential larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

The "HDL-121" message is associated with coding guideline 12. (https://solvnet.synopsys.com/retrieve/015771.html#pipelining).

"HDL-125": Design contains instantiated DW. If the instantiated DW is replaced with an inferred DW OP, it could be extracted.

Example: module test(a,b,c,z); parameter wl = 5; input [wl-1:0] a,b,c; output [2*wl-1:0] z;

wire [wl-1:0] sum; assign sum = (b+a); DW02_mult #(wl, wl)U_mult(sum, c, 1'b0, z); endmodule

The instantiated DW02_mult can be replaced by an inferred multiplier. The following message will be issued:

Information: Cell 'U_mult' in design 'test' can not be extracted because it instantiates 'DW02_mult', which could be inferred with operator '*' instead. (HDL-125)

The instantiated DesignWare component cannot be extracted into datapath blocks. If the RTL design uses inferred the DesignWare operation instead of instantiated DesignWare components, the inferred DesignWare operator might be extracted into a datapath block.

The "HDL-125" message is associated with coding guideline 11. (https://solvnet.synopsys.com/retrieve/015771.html#component_instantiation).

Examples

The following example shows the analysis report that the datapath extraction is broken due to a number of reasons.

```

analyze_datapath_library_cell

Displays function, area and power characteristics of cells from the technology libraries used in datapath generation.

Syntax

status *analyze_datapath_library_cell*

```
[-html_file file]
```

Arguments

`-html_file`

Redirect the output of the report to specified files in HTML format.

Description

This command displays function, area and power characteristics of cells of the library that are used in datapath generation. It also checks for cells or combinations of cells that can improve power QoR during datapath generation.

Examples

The following examples use the demo class.nlib library. The *analyze_datapath_library_cell* command prints some general attributes of the library.

```
-----------------
 Library(s) Used
-----------------

  class (File: /u/test/class.nlib)
  Library units: time=1.00ns voltage=1.00V capacitance=1.00pF
 dynamic_power=1.00pW leakage_power=1.00pW
```

This description is followed by four tables. The first table lists significant cells used in datapath generation.

```
---------------------------------------
 Cells Selected for Datapath Generation

```

The third table lists characteristics for the lowest area and power versions of the library cells. The area, power, and drive-strength characteristics are checked for potential problems and get listed in the fourth table.

The cell characterization table contains the following information for each cell type:

```
Smallest Cell      :  The smallest cell that is found in the library
  Total # Drives    :  Number of different drive strengths for this cell
  Min Area # Drives :  Number of different drive strengths for the
 minimum area version of this cell
  Estim Size        :  Estimated size of the cell based on the estimated
 grid size
                       (= estimated number of grids * estimated grid
 size)
  Actual Size       :  Cell size from the library data
  Dynamic Power     :  Dynamic power from the library data
  Min # Trans       :  Estimated minimum number of transistors required
 to implement the cell
  Estim # Grids     :  Estimated number of grids required to implement
 the cell
                       (= estimated minimum number of transistors / 2 + 1
 border grid)
  Actual # Grids    :  Calculated number of grids for the cell based on
 the area of the smallest inverter in the library
```

The estimations are based on the assumption that each transistor pair occupies one grid and the cell borders together occupy one extra grid (border grid). This does not account for extra grids needed for internal wiring. Therefore, the grid size is estimated to be the area of the smallest inverter cell divided by 2 (1 transistor grid and 1 border grid).

When a potential problem in the cell is detected, an asterisk (*) is added to the value in the characterization table.

```
------------------------------------------------
 Cell Characterization for Lowest Area / Power
------------------------------------------------

   Cell      Smallest     Total  Min Area  Estimated    Actual  Dynamic
  Min  Estimated  Actual
   Type      Cell       #Drives   #Drives       Size      Size    Power

Feedback

analyze_design_violations

Analyzes the specific violations in current design, identifies unfixable violations, and generates a summary report.

Syntax

status *analyze_design_violations*

```
[-type max_trans | static_noise | setup | hold | only_lib]
[-fanout hfn_threshold]
[-slack small_violation_threshold]
[-output output_prefix]
[-stage preroute | postroute]
[-drc_nets nets]
[-endpoints pins]
[-max_slack slack_value]
[-min_slack slack_value]
```

Data Types

hfn_threshold	integer
small_violation_threshold	float
output_prefix	string
nets	collection
pins	collection
slack_value	float

Arguments

`-type max_trans | static_noise | setup | hold | only_lib`

Specifies the type of violation to analyze. Only one type can be specified at each time. By default, the maximum transition violations (*max_trans*) are analyzed.

When type is *static_noise*, static noise violations are analyzed.

When type is *setup*, setup violations are analyzed. For each end point, only the worst path is picked up.

When type is *hold*, hold violations are analyzed. For each end point, only the worst path is picked up too.

When type is *only_lib*, only the library settings that affect optimization are checked. Some messages are reported when buffers or inverters are missing for entire design, for a particular voltage and for a particular site-row. Note that this checking also happens for other types.

Feedback

`-fanout` *`hfn_threshold`*

Specifies the threshold which is used for high fanout net check. The default value at pre-route stage is the value from opt.common.max_fanout, and the default value at post-route stage is the value from extrat.high_fanout_threshold.

`-slack` *`small_violation_threshold`*

Specifies the slack threshold in picoseconds which is used for checking of a small violation. A positive value is required. By default, any slack violation less than 5 ps (*-slack 0.005*) is considered a small violation.

`-output` *`output_prefix`*

Specifies the output file name. The command appends "$type.txt" to the prefix and overwrites the file if there has been one. The output contains a summary of analysis, followed by a list of detailed violations, printed one-by-one in descending order. Violations are also grouped by category. By default, the output file is analyze_design_violations.max_trans.txt.

`-stage preroute | postroute`

Specifies the routing stage used for analysis. Default is *preroute*. The fanout threshold is different at either stage.

`-drc_nets` *`nets`*

Specifies the nets with LDRC violation. Tool only performs analysis on these nets.

`-endpoints` *`pins`*

Specifies the endpoint pins with timing violation. Tool only performs analysis on these nets.

`-max_slack` *`slack_value`*

Specifies the maximum slack of violations that will be analyzed. The violations larger than the value are filtered. It can work with "-min_slack". When "-drc_nets" or "-endpoints" is used, this option is ignored.

`-min_slack` *`slack_value`*

Specifies the minimum slack of violations that will be analyzed. The violations larger than the value are filtered. It can work with "-max_slack". When "-drc_nets" or "-endpoints" is used, this option is ignored.

Description

This command analyzes the specified violations in current design and generates a summary report for them. The violations to be analyzed is specified by -type option. The analyzed result is summarized in log file and is elaborated in a standalone output file. It is important to understand the output.

Feedback

The outputs for LDRC and timing are different. LDRC violations are net based and the result are categories of nets. Timing violations are path based and its result are paths grouped by timing constraints.

First, the output of LDRC is introduced, which is made by 7 parts.

1. Summary of total violations It presents the global view of violations, including violation count, worst and total slack.
2. Categories which causes or may cause LDRC violations unfixable. Categories of Reasons are listed one by one. The abbreviation of reason is in "()". Then the violation number, worst/total cost in the category and the percentage in total are listed. After the separator "|", it is pin info. If there is just "0" after the string of reason, it means no violation belongs to the category.

Note that a violation can match different categories, but it will be put into one. There is internal priority of categories.

"Entire net is dont_touch(D)": All the net segments are dont_touch, no buffer can be added for fixing.

"Net between pad cell and port(PAD)": Such kind of nets are not touched by optimization.

"Tristate nets(TR)": Tristate nets are not touched by optimization.

"Nets with multiple drivers(MD)": Multi-driven nets are not touched by optimization.

"Nets in read-only sub blocks(RO)": Nets in read-only blocks are all dont_touch.

"Nets are highly blocked(BLK)": This means the net's bounding box are highly blocked (blockage ratio > 95%). The buffering will be very difficult, though detouring may solve it.

"Nets with port far from the core area(FP)": Port location is set far from core area. New buffer could not be added outside core area for fixing.

"Large input transition of driver(LI)": It checks the max_trans violation on the input side of driver cell. If there has been large max_trans violation (> 10 * *small_violation_threshold*) on them, current net is grouped here. It is used for max_trans analysis only.

1. Categories about the clock nets. Usually nets on clock network are not touched by signal nets optimization. But if they drive data pins, optimization should also make a fix.

"Clock is used as clock only(COC)": Net is on clock network and drives only clock pins.

"Clock is used as data path only(COD)": Net is on clock network and drives only data pins.

"Clock is used as clock and data(CAD)": Net is on clock network and drives both clock pins and data pins.

"Clock is used as others(CO)": Other definition about the clock nets.

Feedback

1. Categories which help understanding of fixable violations. They are some properties which are not the unfixed reasons but give tips on what remaining violations are. Violations listed here are usually fixable.

"Net is crossing high density area(DEN)": High-density can be a reason to drop a buffering solution. Here the density check is not so identical with optimization. It catches a net here when the density of net's bounding box is over 0.95.

"Net is partially blocked(PB)": This category means there is high-density around any of the pins in the net.

"Connect to excluded cell of XMB(XME)": The excluded cells of a module-based exclusive move bounds are allowed to place outside of the bounds. Once buffering happens, new buffer belongs to the bound and can only be placed inside bound. So, if excluded cells are far away from the bound, no buffering can fix the violation.

"Connect to excluded cell of HMB(HME)": This is the same as "XME", the difference is that the type of move bound is module-based hard move bound. However, Hard move bounds are suggested to remove during optimization, since hard move bounds are not honored by optimization.

"Nets across different exclusive MBs(DXM)": Violation on nets which are crossing boundaries of exclusive move bounds may be unfixed due to unknown limitation. User can pay attention to them.

"Nets across different hard MBs(DHM)": Violation on nets which are crossing boundaries of exclusive move bounds may be unfixed due to unknown limitation. User can pay attention to them. However, Hard move bounds are suggested to remove during optimization, since hard move bounds are not honored by optimization.

"Some segments of net are dont_touch(PD)": Some net segments of the net are dont_touch. Though there are still bufferable net segments, it is not sure whether buffering can happen.

"High fanout nets(> $Threshold)(HF)": The nets whose fanout number is larger than $Threshold are grouped here. For pre-route stage, the value comes from opt.common.max_fanout, and for post-route stage, the value comes from extrat.high_fanout_threshold. The threshold value is present here.

"Nets crossing different voltage areas(MV)": The nets crossing multiple voltage areas are quite complicated. They are grouped here but lack of sufficient analysis. User can refer to "check_bufferability" commands.

"Nets with small violation(> $Threshold)(S)": Small violations are not analyzed but it does not mean optimization does not work on them. The threshold value is listed here and can be changed by "-slack" option.

Feedback

"Nets are too short(TS)": If the net length is smaller than a threshold, the net is grouped here. The threshold is decided by internal grid size. If a net has been short, buffering does not help for LDRC and setup. It is necessary to find other reason.

"Nets are long(> 400.0um)(LN)": The nets whose length is over 400 um are grouped here. It is not reasonable to leave so long nets. User needs to check out real reasons.

"Other violations(OV)": Those violations which could not be grouped to above categories are all here.

1. Distributions of fixable violations. For LDRC violations, there are four distributions, including slack, fanout, net length and constraint. The distributed violations are those fixable ones. Now the boundaries of distribution cannot be changed.
2. Top 10 Violations and their category given by abbreviation.
3. Guidance to find detailed report. The report file is $prefix.$type.txt, e.g. analyze_design_violations.max_trans.txt. In the report file, the info in the regular log is also printed. And following that, there is elaboration of violations. The elaboration is also grouped by category. This means violations with the same reason are shown together. In each category, the violations are printed in descending order. For each violation, there are net name, worst pin name, constraint, slack and scenario. For static noise violation, worst pin is always the net driver. This is an example of a violation.

```
ropt_net_329531
  Worst Pin: PMB_inst/rst_n
                                        0.200,   -0.006,
 ta_test_ss28_0.75V_m0.60VS_0.60GS_m40C_SigCmax
```

For

1. Summary of total violations This is similar to LDRC analysis. The summary includes violated path count, worst and total slack.
2. Categories listed by timing constraints that may be over-set. There are some descriptions with the word "large" in the categories. The reference is 10% of the clock period. "large" means that the checked thing is greater than the reference value. However, this does not mean the violation is unfixable due to the too "large" setting. It is just a potential reason. A path may match different categories, but it can only be grouped to the worst category. In the detailed log file, all categories are listed for top 10 paths.

"Large clock skew(LCS)": clock skew is the gap between delay to clock pin of launch register and clock pin to capture register. For setup, it is clock delay of launch register minus clock delay of capture register. For hold, it is opposite. The larger clock skew is, the less room for either setup or hold fixing.

"Large external input delay(LID)": External Input delay occupies arrive time. The larger it is, the less room for setup fixing.

Feedback

"Large driver adjustment(LDA)": Driver adjustment occupies arrive time. The larger it is, the less room for setup fixing.

"Large clock uncertainty(LCU)": For setup, clock uncertainty tightens require time. The larger it is, the less room for setup fixing. For hold, clock uncertainty increases require time. The larger it is, the more delay at path should be added.

"Large setup time of end point(LLS)": Setup time tightens require time. The larger it is, the less room for setup fixing.

"Large external output delay(LOD)": For setup, external output delay tightens require time. The larger it is, the less room for setup fixing. For hold, external output delay increases require time. The larger it is, the more delay at path should be added.

"Large hold time of end point(LLH)": Hold time increases require time of hold. The larger it is, the more delay on path should be added.

"Delay setting is illegal(ID)": Delay is set as negative value.

"Conflict with setup at endpoint(CSE)": This is for hold analysis only. When setup is also violated, fixing hold will degrade setup.

"Path ends up at scan in pin(SIP)": End point of path is scan in pin of register.

"Inter-clock violated paths(ICVP)": The capture clock and launch clock are different for the hold timing path.

"POCV related violation path(POCV)": Hold violation is caused by turning on POCV.

"Small violations(SM)": Small violations are not analyzed but it does not mean optimization does not work on them. The threshold is 5 ps and can be changed by "-slack" option.

"Remaining violating paths(OT)": It contains all violations which are not grouped to any of above categories.

1. Distribution of uncategorized violations by slack Distributed violations are from "Remaining violating paths". Now the boundaries of distribution cannot be changed.
2. Top 10 Violations and their category given by abbreviation.
3. Guidance to find detailed report. In the file of timing analysis report, it also prints the summary first and then the elaboration of paths. The elaboration is different from LDRC analysis. It does not follow the category. The paths are printed in the descending order of slack. Besides some timing info, the path analysis result is listed. There could be more than one category. For top

Feedback

10 violations, the buffering capability of nets along the path is also analyzed, which uses the same way as max_trans analysis.

analyze_lib_cell_placement

Analyze a collection of library cells for their ability to be placed in the current design.

Feedback

Syntax

```
status analyze_lib_cell_placement
-lib_cells cells
[-trials num_trials]
[-region {{llx lly} {urx ury} }]
[-no_pg_drc]
[-no-adv]
[-multiva]
[-max_cells rpt_max]
[-threshold pass_thresh]
[-directory drc__directory]
[-drc_limit num_drcs]
[-seed random_seed]
[-ignore_dont_use]
[-find_zero_pass_rate_only]
[-verbose]
```

Data Types

cells	collection
num_trials	integer
llx	float
lly	float
urx	float
ury	float
rpt_max	integer
pass_thresh	float
drc_directory	string
num_drcs	integer
random_seed	integer
ignore_dont_use	boolean
verbose	boolean

Arguments

`-lib_cells` *cells*

Specifies the library cells to analyze for placeability. This is a required option.

`-trials` *num_trials*

Specifies the number of random sites at which to test the legality of each lib cell. The default is 1000. A value of 0 will force an exhaustive search of all free sites in the design.

`-region { {llx lly} {urx ury} }`

Specifies a bounding box in which to search for legal sites. Library cells will be considered legal for sites in the region only if they remain wholly withing the region.

Feedback

`-no_pg_drc`

This option disables pnet checking (the "pg_drc" rule in the Advanced Legalizer).

`-no-adv`

No advanced rule checking will be performed if this option is specifed.

`-multiva`

Specifies to analyze library cells as per multiple voltage areas and sites.

`-max_cells` *`rpt_max`*

Specifies the maximum number of cells to list in the report. The default is 100. The true limit is the minimum of *rpt_max* and the number of lib cells specified.

`-threshold` *`pass_thresh`*

Specifies the threshold pass rate. Only cells whose pass rate is less than this will be reported. The default is 1.0, that is, 100%.

`-directory` *`drc__directory`*

Specify a directory for DRC violation files and failure annotation scripts. The default is the current directory.

`-drc_limit` *`num_drcs`*

Specify a limit for how many DRC violations are written to each DRC file. The default is 100.

`-seed` *`random_seed`*

Specifies the seed value for random selection of free sites at which to test the legality of each cell. The default is 1010.

`-ignore_dont_use`

Specifies whether or not to include library cells with dont_use attribute during variant group pass rate analysis. The default is false.

`-find_zero_pass_rate_only`

Specifies if only zero percent pass rate library cells are to be found.

`-verbose`

Provides detailed information about failures in some modes. See below.

Description

This command tests a collection of library cells for their ability to be placed in a the current design. For each library cell in the collection, *num_trials* free sites are selected at random. If a region is specified, then the list of random sites is limited to free sites within that area.

Feedback

Sites are randomized based on *random_seed* value. If the cell can be placed at that site in any orientation, then it is considered to pass at that site. If it cannot, it is considered to fail at that site. The pass rate for the cell is the number of passing sites divided by the number of sites tested.

After all of the cells have been analyzed, a report is produced listing cells in order of increasing pass rate. The length of this report is limited by the *rpt_max* argument. It is also limited by the *pass_thresh* argument. No cells whose pass rate is above this will be reported.

With DRC enabled (without using the -no_pg_drc option), when a lib cell has DRC violations, a file is created containing the violations. The file is named *analyze.libCellName.drc*. By default these files are written to the current directory. You can specify a directory using the *-directory drc_directory* option. By default, up to 100 DRC violations will be written into the file. You can change the limit using the *-drc_limit num_drcs* option. Setting *num_drcs* to zero means to write all violations. Also note that whatever directory you choose, existing drc files will be overwritten.

Multi threading is available when using the advanced legalizer. The maximum number of threads is obtained from the value set with the *set_host_options* command, but may be lowered based on the size of the site map.

Variant group pass rates are reported for EEQ cells/library cells belonging to variant groups, along with their individual pass rates, if AL and variant aware legalization are enabled. User is expected to pass all the library cells belonging to a variant group to ensure accuracy. By default, the library cells with the dont_use attribute set to true would be ignored from variant group analysis. You can change this behaviour by setting *ignore_dont_use*.

If *find_zero_pass_rate_only* option is used, only lib cells with zero percent pass rate will be found and have the pass_rate attribute set. Existing pass_rate attribute on library cells will be removed, if the pass rate is not zero.

For hybrid designs or other designs using the ALMap version of cellmap, you can use the *-verbose* option to get more details about failures. When *-verbose* is used, any time a lib cell fails at a specific location, detailed information is collected about the failure. At the conclusion of the command, two things happen: for each failure, a one-line message is generated, and for each lib-cell with failures, a script is written with commands to annotate the failures on the GUI. An example message might be:

```
Warning: lib cell AN2 failed at {27.132 2.88}: Basic Rules (ALCP-002)
Warning: lib cell AO3 failed at {318.24 2192.61}: pin_color_align
 (ALCP-002)
```

If there are different failures for different orientations, then the message includes the rule that caused the failure for each orientation. The annotation scripts are written to the same directory as the DRC files (see *-directory* above). Each script can be sourced to display the failures on the GUI as annotation shapes named ALCP_FAIL_n, where n is numbered

Feedback

starting from 0. Each annotation is a rectangle, sized as the lib cell it represents. It is labeled with the failure reason. You can select the annotation shapes and walk thru them to analyze the failures. The script is designed to delete any existing ALCP annotations, as the GUI can get cluttered quickly if you have a lot of failures. If you want to keep failures for multiple lib_cell's on screen, you can set a Tcl variable, *dontClearAlcpAnnotations*, to any value. You can remove these annotations yourself with:

```
remove_annotation_shapes [get_annotation_shapes -quiet ALCP_FAIL_*]
```

You should remove them prior to saving the NDM to reduce unnecessary clutter. Note that these scripts produce annotations, not instances. It's just a simple way to visualize where the failures are.

Examples

The following example analyzes all opened designs.

```
prompt> analyze_lib_cell_placement -lib_cells [get_lib_cells -filter
 is_open==true]
```

analyze_mv_design

Analyzes multivoltage design connections

Syntax

status *analyze_mv_design*

```
-level_shifter
[-through]
[-global_report]
[-output <output_file>]
[-html]
[-csv]
[-nosplit]
[-verbose]
[-example]
```

Data Types

```
through     list
output_file string
```

Feedback

ARGUMENT

-level_shifter

Enables level-shifter analysis. Required option, must be used with either [-global_report] or with [-through].

-through

Specifies a net or pin, and will report the global net containing that pin/net.

-global_report

Make an analysis of level-shifter insertion on the whole design, and counts one error for each driver-load pair.

-priority

The errors for global_report are picked based on a priority list, with this command you can change the order in which an error is selected in a driver-load pair.

The available priorities are:

1. Missing or Problem with UPF constraint (MPC).

   An error will be classified as MPC if:

   a. There is no domain boundary

   b. There is a Missing strategy (LS or ISO)

   c. Strategy cannot be fulfilled because there is a problem that prevent LS insertion.

2. Problems that result in the maximum number of violations for that global net (FO).

   This counts the number of loads that a specific error is affecting, so the one that is affecting more loads is going to have more priority.

3. Library violation (LV).

   An error will be classified as LV if it is related to missing library cell, for example: problem with map command (LS or ISO), main rail violation or no library cell matches the operating conditions.

4. Supply violation (SV).

   An error will be classified as SV if there is any problem with supplies availability.

5. Dont touch (DT).

Feedback

Net has dont touch.

6. Closer to load (CL) Last resource to avoid ties. This counts the number of power domain (PD) boundaries are between the error and the load, the one with less PD boundaries between the error and the load is going to be chosen if all other categories are the same.

The command will receive a list with the priority order, if this is not given the default priority will be used {MPC FO LV SV DT CL}

-verbose

Generates detailed information in the report. For -through, add the list of supplies and list of lib cells. And for -global_report add the list of drivers for each error.

-output <*output_file*>

Print report into <*output_file*>.

-html

Print report in HTML format.

-csv

Print report in CSV (Comma-Separated Value) format. *-output* option is required when using this option and cannot be used in conjuntion with the *-html* option

-nosplit

Most of the reported data is listed in fixed-width columns. If the data for a given column exceeds the column width, the next field begins on a new line, starting in the right column. The *-nosplit* option prevents this behavior, allowing all the data to be written on a single line.

-example

Show example of different usages for analyze_mv_design.

Description

The analyze_mv_design command performs multivoltage analysis and reports design details that can help understand why level-shifter insertion failed. You can perform level-shifter analysis by using the -level_shifter with -global_report or with -through. The level-shifter analysis through a global net lists variable settings, driver and load information, signal connections, library availability information, and errors and warning collected from create_mv_cells.

Feedback

Examples

The following examples are for -level_shifter -global_report and -level_shifter -through:

```
prompt> analyze_mv_design -level_shifter -global_report

analyze_mv_feasibility

Analyzes multi voltage design ISO/ELS/Retn/LS cell mapping/insertion feasibility.

Syntax

status *analyze_mv_feasibility*

Feedback

```
[-isolation]
[-enable_level_shifter]
[-retention]
[-level_shifter]
[-element]
[-format html|text]
[-nosplit]
[-verbose]
```

Arguments

`-isolation`

Report isolation cell mapping feasibility.

`-enable_level_shifter`

Report enable level shifter cell mapping feasibility.

`-retention`

Report retention cell mapping feasibility.

`-level_shifter`

Report level_shifter cell insertion feasibility.

`-element`

Report the indicated element mapping/insertion feasibility.

`-format`

Generate html format report file or text report only.

`-verbose`

Report detailed information with domain information and all library cells information in html report.

`-nosplit`

Specifies the report to be printed in none split mode in texture report. Each table row is printed in one line instead of multiple lines.

Description

This command analyze multi voltage design ISO/ELS/Retn mapping and/or LS insertion feasibility. If any potentially inserted ISO/ELS/Retn cannot be mapped or path voltage violation cannot be fixed by LS insertion due to any reason, the report is generated, the failure reason for individual cell or the path is listed in texture report. If specified with -format html, html format report is generated, detail information/properties of the ISO/ELS/Retn/LS cell or path is listed. For example, cell reside domain and supplies information, cell associated strategy and specifications, detail reason of each failure mapping library cell information. Or global path with voltage violation, with global path details including

Feedback

driver, loads situation, domain boundary(ies) situation, strategy application, and library cell checking information.

-element can only be specified with one type of cell report, different type of cell report accept different type of element. E.g. isolation cell report accept instance or pin/port as element input, level shifter cell report accept pin/port/net as element input.

Retention mapping is done in compile_fusion flow, please run compile first to get the correct retention mapping report with details if any cell cannot be mapped.

In verbose mode, html report also displays detailed information from domain, boundary ports, all library cells/attributes/PG or Data pin information.

Examples

The following example reports the information of why ISO cells is left unmapped

```

Error: Not all the level shifter cells can be mapped, please refer to
 HTML report mv_feasibility.1/mvFeasibility.html  on why level shifter
 cell(s) cannot be inserted. (UPF-909)
1

For -iso, -els, -retn, if need to check detail of library cell properties
 and strategy properties including PVT setting,
enable the html report generation then explore the html.

To enable the html report:  analyze_mv_feasibility -format html or
set_app_options -as_user_default -list {mv.upf.enable_amvf_html_report
 true}

For -level_shifter, html report always be generated.

Feedback

analyze_pg

Performs EMIR analysis. This command generates the data needed for pg integrity checks, and provides various settings and options to configure the analysis flow. Results are saved to EMIR database and can be used for further debugging or reporting.

Syntax

status *analyze_pg*

```
[-type static | transient]
[-nets net_name_list]
[-no_auto_load]
[-result result_name]
[-use_global_host_options use_global_host_options]
[-host_options host_option_names]
[-flow feasibility | prototype | implementation]
```

Data Types

```
net_name_list           collection
result_name             string
use_global_host_options string/bool
host_option_names       string
```

Arguments

`-type static | transient`

Determines the type of analysis. The value could be static or transient. The default type is static.

`-nets net_name_list`

Specifies the nets for analysis, *net_name_list* can include the wildcard characters "*" and "?". The default value is "*".

`-no_auto_load`

By default, *analyze_pg* populates the latest EMIR analysis result to memory. If you have no intention to debug the output in the same session, you can avoid auto-loading results and review the results by loading from EMIR database in another session.

`-result result_name`

Specifies the directory name for saving the EMIR analysis result. The default value is "default".

Feedback

`-use_global_host_options` *use_global_host_options*

Uses CDPL laucher and the unnamed global host options. This option is exclusive with *-host_options*. It can be true|false or 1|0. The default value is "false".

`-host_options` *host_option_names*

Specifies that the given host option must be used for distributed processing. If not specified, the tool looks for the global host option and use the global host option if it has distributed processing settings. This option is exclusive with *-use_global_host_options true*

`-flow feasibility | prototype | implementation`

Determined the flow kind. The value could be feasibility, prototype or implementation. The default flow is prototype.

Description

This command prepares the data needed for EMIR analysis and provides various settings and options to configure the flow. Results are saved to the EMIR database.

Examples

The following example performs EMIR analysis and saves result in the generated directory "myResult" in EMIR database.

```
prompt> analyze_pg -result myResult
```

---

analyze_power_plan

Analyzes a complete or partial power network for voltage (IR) drop and electromigration on the specified power and ground nets. This command also calculate track utilization by P/G in each layer.

Syntax

status *analyze_power_plan*

```
[-nets net_list]
[-power_budget power_budget]
```

Feedback

```
[-voltage voltage]
[-read_power_file power_file_name]
[-analyze_power]
[-pad_references power_pad_reference_name]
[-use_terminals_as_pads]
[-report_track_utilization_only]
```

Data Types

net_list	collection or list
power_budget	float
voltage	float
power_file_name	string
power_pad_reference_name	string

Arguments

`-nets net_list`

Specifies the power or ground nets on which to perform power network analysis. This is a required option if the *-report_track_utilization_only* option is not specified.

`-power_budget power_budget`

Specifies a total power budget for the design on which to perform power network analysis. The power budget is divided among the instances according to the cell area. For hard macros or standard cells, the power budget is computed based on the percentage of the total area. For hierarchical blocks, the power is computed based on the total area of all their child cells and blocks inside. The unit is in mW.

For example, if the power budget for the entire design is 500 mW, the total area of the top-level blocks is 500,000 square microns, and one of the blocks has an area of 25,000 square microns, power network analysis allocates the power for that 25,000-square-micron block as follows:

```
500mW * (25,000/500,000) = 25mW
```

Either *-power_budget* or *-read_power_file* should be specified to provide power data.

`-voltage voltage`

Specifies the voltage of the net to be analyzed. The voltage is applied at the power pad. The voltage unit is volts. The default is 1.5.

`-read_power_file power_file_name`

Obtains the power calculation source from a side file. By default, this option is off. The supported power files are PT-PX power output file, and default power

Feedback

file. The format of the default power file is as follows. Instance *instance_name power_value*

`-analyze_power`

Specifies the option to get power consumption as report_power. The option will use it for IR-drop calculation.

`-pad_references` *`pad_references`*

Specifies the pad references and the associated net as follows

`net_name``:`*`pad_reference_name`*

If net name is not specified, the pad reference is used for all the analyzed nets. By default, PNA will assume all the pads logically connected to signal *1* or *0* as power pads.

`-use_terminals_as_pads`

Use terminals of top block as power/ground pads. By default, the option is off. This option treats terminals as additional power/ground pads. They can exist while using virtual pads. PNA will not make virtual connection if no P/G wires connect to them.

`-report_track_utilization_only`

If the option is used, all the other options are not required. This option will report the percentage of track resource is occupied by P/G wires but skip calculating IR drop. If the option is not used, PNA will still calculate track utilization percentage and perform IR-drop and EM calculation.

Description

This command performs a power network analysis (PNA) in a complete or partial power/ground network during the design planning stage. If the power ports in standard cells and hard macros are not connected to the power and ground network, PNA creates virtual connections to those unconnected power ports. PNA then analyzes the IR drop and electromigration in the power network based on user-specified power budget and voltage supply. This command requires that at least one cell in the design is logically connected to the power or ground net being analyzed. If not, you should use the *connect_pg_net* command to create the logic connection first. If there are any power switches that are connected to the analyzed net, you should set up a suitable resistance to power switches before you use this command. If not, PNA will assign a very small resistance to all unspecified power switches. To set up resistance of power switches, you can use *set_attribute* to set power_switch_resistance or *plan.pna.power_switch_resistance* application option as follows:

set_app_options -name plan.pna.power_switch_resistance

Feedback

This command also calculates track utilization. Power, ground and secondary nets are taken into account. Only preferred routing direction defined in tech file is considered as routing resource. The resource of each routing layer that P/G wires utilize is displayed in the log.

Examples

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW.

```
prompt> analyze_power_plan -nets VDD -power_budget 1000
```

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW using pad reference VDD_NS

```
prompt> analyze_power_plan -nets VDD -power_budget 1000 -pad_references
 "VDD_NS"
```

The following example analyzes the IR drop on the *VDD* net with a total power budget of *1000* mW using pad reference VDD_NS for VDD and VSS_NS for VSS.

```
prompt> analyze_power_plan -nets {VDD VSS} -power_budget 1000 \\
   -pad_references "VDD:VDD_NS VSS:VSS_NS"
```

The following example analyze the IR drop on the *VDD* net with a total power budget of *1000* mW with power switch cell (50 Ohm)

```
prompt> set_attribute [get_cells power_switch_cell_name]
 power_switch_resistance 50
prompt> analyze_power_plan -nets {VDD} -power_budget 1000

or

prompt> set_app_options -name plan.pna.power_switch_resistance -value \\
   {{power_switch_lib_cell_name1 50}}
prompt> analyze_power_plan -nets {VDD} -power_budget 1000
```

See Also

- set_virtual_pad
- plan.pna.power_switch_resistance

---

analyze_rail

Performs the targeted rail analysis on the specified nets. This command generates the data needed to run the RedHawk tool and runs the RedHawk tool within the current tool session. This command enables several target analyses, such as power and ground

Feedback

network voltage drop analysis, electromigration analysis, and minimum path resistance analysis. A previously generated RedHawk command script can also be used to perform the analyses.

SYNTAX

(ICC2)

status *analyze_rail*

```
[-redhawk_script_file redhawk_script | -nets net_list]
[-voltage_drop static | dynamic | dynamic_vcd

[-primepower_script_file file_name]
[-twf_generation icc2 | pt]
[-ipf_generation icc2 | pt]
[-check_only]
[-check_mode mode]
```

(3DIC Compiler)

status *analyze_rail*

```
[-voltage_drop static]
[-electromigration]
[-extra_gsr_option_file]
```

Data Types

file_format	string
file_name	string
nets	collection or list
redhawk_script	string
result_name	string
strip_path	string
time	string

Feedback

Arguments

`-redhawk_script_file` *redhawk_script*

Specifies and uses an existing RedHawk script to perform the RedHawk run.

This script is usually generated from an earlier *analyze_rail* run.

When a user-specified script file is used, all other currently enabled options are ignored. For example, if you run the *analyze_rail -voltage_drop static -redhawk_script_file myscript.tcl* command, the -voltage_drop option is ignored.

This option and the -nets option are mutually exclusive.

`-nets` *net_list*

Specifies the power and ground supply nets to be analyzed. This option is required if the -redhawk_script_file option is not set.

The tool considers all the switched or internal power nets of the specified power nets in the analysis. You do not need to explicitly specify the internal power nets.

If the -nets option is selected, you need to specify at least one of the following options: *-min_path_resistance* or *-voltage_drop*.

This generates extra VDD_NETS and GND_NETS blocks in the GSR file.

Each specified power net must have a corresponding *supply_net* defined with its *voltage_min* attribute set. The *voltage_min* attribute may be set using the *set_voltage* command.

`-voltage_drop` *static* | *dynamic* | *dynamic_vcd* | *dynamic_vectorless* | *sigma_dvd* | *sigma_pd* | *sigma_av*

Performs voltage drop analysis on the specified power and ground nets.

When this option is selected, the tool checks for voltage drop violations on the specified power and ground supply nets. The results are saved under the current rail database directory, set by the rail application option rail.database, or the RAIL_DATABASE directory (the default). After the /fBanalyze_rail/fP command completes operation, the *open_rail_result* command is automatically invoked so users can view results in the GUI. It generates a voltage drop map, a parasitics map, and a power map. In addition, it reports voltage drop violations in a text file and in an error view.

`-generate_file {<`*TWF* | *LEF* | *DEF* | *SPEF* | *PLOC* | *IPF*`> ...}`

Specifies Redhawk/Redhawk-SC collateral types to generate.

The default value is empty.

Feedback

`-switching_activity {`*`file_format`* `[`*`file_name`*`] [`*`strip_path`*`] [`*`time_window`*`]}`

Specifies an optional switching activity file. The *file_format* argument can be *VCD* (a VCD file generated from a gate-level simulation), *FSDB*, *SAIF*, or *ICC_ACTIVITY*.

A VCD or SAIF file can reference a top-level design in a different hierarchy than the one used in the current session. The *strip_path* argument removes the specified string from the beginning of the object name. Using this option modifies the object names in the VCD or SAIF file to make them compatible with the object names in the design library.

For example, use the following option to load a VCD file and strip the /top_design/cup_module prefix from all object names.

```
-switching_activity {VCD top_design.vcd /top_design/cup_module}
```

For example, use the following option to load a VCD file without a strip path.

```
-switching_activity {VCD top_design.vcd}
```

If you have annotated switching activity on the design in the IC Compiler II environment, set the *file_format* argument to *ICC_ACTIVITY*. When you specify this format, the tool creates a temporary SAIF file that contains the user-annotated switching activity and passes it to the RedHawk tool. The *file_name* argument does not apply to this format.

When the *file_format* arguement is set to *VCD* or *SAIF*, the tool generates a VCD_FILE or SAIF_FILE block in the GSR file, respectively.

When the *strip_path* argument is specified, the tool generates the *FRONT_PATH* component in the VCD_FILE block, or the *ROOT_INSTANCE* component in the SAIF_FILE block. Both VCD_FILE and SAIF_FILE blocks are in the GSR file.

When the *time_window* argument is specified, the tool generates the *SELECT_RANGE* component in the VCD_FILE block in the GSR file.

`-electromigration`

Performs electromigration analysis on the specified power and ground nets.

When enabled, the tool analyzes the current density on the specified nets and identifies the segments with potential electromigration issues. It also calculates current violations based on the default rules that are loaded in the design library. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the *analyze_rail* command completes, the *open_rail_result* command is

Feedback

automatically invoked, so you can view the results in the GUI. It generates a electromigration map and reports the current violations in an error view.

The -electromigration option must to specified with the -voltage_drop option.

When analysis run is complete, the tool adds the RedHawk "perform emcheck" command in the run script.

`-min_path_resistance`

Performs minimum path resistance analysis on the specified power and ground nets. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the *analyze_rail* command completes, the *open_rail_result* command is automatically invoked so you can view the results in the GUI. It generates a minimum path resistance map.

If you want to perform minimum path resistance analysis only, do not use the -voltage_drop option.

When analysis run is complete, the tool adds the RedHawk "perform gridcheck -limit -1 -fullchip" command to the run script.

`-effective_resistance`

Performs effective resistance analysis on the specified power and ground nets. The results are saved under the current rail database directory, set by rail application option rail.database, or the RAIL_DATABASE directory (the default). After the *analyze_rail* command completes, the *open_rail_result* command is automatically invoked so you can view the results in the GUI. It generates an effective resistance map.

When analysis run is complete, the tool adds the RedHawk "perform res_calc" command in the run script.

See the *report_power* command man page for more information.

`-result_name` *`result_name`*

Specifies the directory name for saving the rail analysis results. The results are saved in {design_name}/rail/{result_name} directory under the current rail database directory, set by the rail application option rail.database, or by default under the RAIL_DATABASE directory.

The default result name is REDHAWK_RESULT.

Subsequent analyses overwrite the previous analyses results.

This generates an INSTANCE_POWER_FILES block in the GSR file.

Feedback

`-check_missing_via`

Performs missing via check.

When checking is complete, the tool adds the RedHawk "mesh vias -report_missing" command in the run script.

"-check_missing_via" requires "-voltage_drop".

`-extra_gsr_option_file`

Specifies an external GSR file to include at the tail of the generated GSR file.

This generates extra INCLUDE statements at the end of the GSR file, and overrides the application option settings.

`-script_only`

Generates the RedHawk script and the input data for the target analysis, such as voltage drop, minimum path resistance or electromigration, without actually executing the analysis run.

This allows you to modify and reuse the run script as desired.

`-rail_scenarios` *`rail_scenario_list`*

Specifies a list of rail scenarios to launch.

If rail.enable_new_rail_scenario set to true, and "-rail_scenarios" is used, the tool launches rail scenarios specified by "-rail_scenarios". If rail.enable_new_rail_scenario set to true, and "-rail_scenarios" is not used, the tool launches rail scenarios associated with a design scenario with "-ir_drop" set to true. If rail.enable_new_rail_scenario set to false, and "-rail_scenarios" is used, the tool errors out. If rail.enable_new_rail_scenario set to false, and "-rail_scenarios" is not used, analyze_rail honors other command options.

The default value is empty.

`-submit_to_other_machines`

Launches RedHawk on a separate machine. This option should be used with the *set_host_options* command to set a specific machine or farm.

`-multiple_script_files {{`*`result_name script_file`*`}...}`

Launches multiple RedHawk jobs using multiple script files provided in the option. When analysis is finished, each result is saved with the result_name specified. This option has to be used with the -submit_to_other_machines option, and the *set_host_options* option where a farm machine system has to be set.

The number of licenses required is equal to the number of script files provided. If there are not enough licenses available, the *analyze_rail* command aborts

Feedback

with an error message. If you want to run *analyze_rail* when the number of available licenses is less than the number of scripts, use *set_app_options -name rail.license_checkout_mode -value wait* before invoking the *analyze_rail* command. The tool launches scripts based on the number of the available licenses, and puts other scripts waiting for an available license. A license is released from other sessions or from the same session when a script finishes the job. With this application option set to *wait*, the license checking is performed dynamically when scripts are running during the *analyze_rail* command run.

`-bg`

Launches RedHawk in the background process and returns shell to the user. Use the *report_background_jobs* command to check if a previous background job has completed. Below restrictions apply: - Recursive -bg is not allowed. - Overlapping background jobs is not allowed. - RAIL_DATABASE related commands and license-related commands are not allowed in the background jobs.

`-step_size`

For RedHawk-SC flow, generates the *step_size* argument used by *create_analysis_view* command in analyze_rail.py file generated by the *analyze_rail* command.

The default value: For technology 5nm or below, use 5ps as the step size. For technology above 5nm, use 10ps as the step size. If technology is not specified, by default technology is set to 7nm. Use the application option *rail.technology* to specify the technology.

`-stop_time`

For RedHawk-SC flow, generates the *max_duration* argument used by the *create_analysis_view* command in the analyze_rail.py file generated by the analyze_rail command.

The default value: Always use 4x dominant clock period as the maximum duration. If the calculated max duration is smaller than step size, then the maximum duration is equal to 10x step size.

`-primepower_script_file` *`file_name`*

Pass a script file for PrimePower and the valid commands will be written in the post_script_file, and they will be executed before generating IPF. Note that this option is for in-design PrimePower flow so it only works with *-ipf_generation pt*. The following are the valid keywords for a script file: ["set_eco_options", "check_eco", "report_eco_options", "read_context_leakage_data", "set_switching_activity", "set_app_var"]

Feedback

`-twf_generation` *`icc2 | pt`*

When *twf_generation icc2* is enable, timing window file (TWF) will be generated by ICC2. Besides, when *twf_generation pt* is enable, PrimeTime engine is used to do sign-off STA for twf generation.

`-ipf_generation` *`icc2 | pt`*

When *ipf_generation icc2* is enable, instance power file (IPF) will be generated by ICC2. Besides, when *ipf_generation pt* is enable, PrimePower engine is used to generate ipf.

`-check_only`

Enable pre-checking function to check arguments, settings, and input collateral without actually executing the analysis run.

`-check_mode` *`mode`*

Specify check mode for pre-checking. Currently, "fast" is the only valid mode "-check_mode" only works when "-check_only" is enabled.

Description

This command prepares the data needed for RedHawk rail analyses, and then calls RedHawk or RedHawk-SC to perform the specified rail analysis run. The supported rail analyses are voltage drop analysis, electromigration analysis, minimum path resistance analysis, and effective resistance analysis.

The results are saved under the current rail database directory, set by the rail application option rail.database, or the RAIL_DATABASE directory (the default). After the *analyze_rail* command completes, the *open_rail_result* command is automatically invoked, so you can view the results in the GUI. The command generates error views that capture violations found during the analysis. You can display the generated errors in the error browser, depending on the analysis options you chose.

This command should only be invoked when interposer die is the current block in a 3DIC design in 3DIC shell.

You can perform multiple analyses, such as voltage drop and electromigration, in a single run.

The generated analysis results include the following information:

- Average voltage drop values in a map file
- Average electromigration values in a map file
- An error cell with average electromigration values

Feedback

There are several rail application options that are used by the *analyze_rail* command:

- rail.redhawk_path to specify the RedHawk executable path For example:

```
prompt> set_app_options -name rail.redhawk_path \\
   -value /release/latest/Testing/bin
```

- rail.database to specify where to save the RedHawk analysis results (the default is RAIL_DATABASE) For example:

```
prompt> set_app_options -name rail.database -value my_rail_output
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example performs static voltage drop analysis for the nets {VDD VDDV} using native power analysis:

```
prompt> create_taps -import my.tap
prompt> analyze_rail -nets {VDD VDDV} -voltage_drop static
 -ipf_generation icc2
```

The following example performs minimum path resistance analysis for the net VDD:

```
prompt> create_taps -import my.tap
prompt> analyze_rail -nets VDD -min_path_resistance
```

The following example specifies a time window for the VCD file which is used to run dynamic rail analysis on the net VDD.

```
prompt> analyze_rail -voltage_drop dynamic_vcd -nets vdd \\
   -switching_activity {VCD top_design.vcd /top_design/cup_module \\
      {start_time end_time}}
```

The following example specifies a time window for the FSDB file which is used to run dynamic rail analysis on the net VDD.

```
prompt> analyze_rail -voltage_drop dynamic_vcd -nets vdd \\
   -switching_activity {FSDB top_design.fsdb /top_design/cup_module \\
      {start_time end_time}}
```

The following example submits a RedHawk job to an LSF farm.

```
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P
 bnormal}
prompt> analyze_rail -voltage_drop dynamic -submit_to_other_machines
```

Feedback

The following example launches multiple RedHawk jobs to farm machines to have both static and dynamic rail analyses running at the same time. Two SNPS_INDESIGN_RH_RAIL licenses will be checked out.

```
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P
 bnormal}
prompt> analyze_rail -multiple_script_files {{static static.tcl} {dynamic
 dynamic.tcl}} -submit_to_other_machines
```

The following example assumes only 2 licenses are available, but needs to launch 4 RedHawk script files in the same analysis run. Since *set_app_options -name rail.license_checkout_mode -value wait* is set, the *analyze_rail* command launches 2 scripts first and puts other 2 scripts waiting for a license to be available.

```
prompt> set_app_options -name rail.license_checkout_mode -value wait
prompt> set_host_options -submit_protocol lsf -submit_command {bsub -P
 bnormal}
prompt> analyze_rail -multiple_script_files {{result1 result1.tcl}
 {result2 resilt2.tcl} {result3 result3.tcl} {result4 result4.tcl}}
 -submit_to_other_machines
```

The following example launches RedHawk in background process and shell is returned to user.

```
prompt> analyze_rail ... -bg
prompt>
```

---

analyze_subcircuit

Invokes circuit simulation on a subcircuit of the current design. This command is suitable for analyzing clock mesh nets.

Syntax

status *analyze_subcircuit*

```
[-name string]
[-from pins]
[-to pins]
[-net net]
[-simulator name_of_simulator ]
[-spice_header_files list_of_files]
[-driver_subckt_files list_of_files]
[-configuration list_of_scenario_configurations]
[-clock clock_name]
[-spef_input_file_suffix string]
[-rc_include_file_suffix string]
[-num_simulation_cycles int]
[-simulation_time float]
[-remove_escaped_char]
[-extraction]
[-create_spice_deck]
[-run_simulation]
[-write_annotation]
[-apply_annotation]
[-include_power_analysis]
[-max_only]
[-min_only]
[-distributed_sim_setting string]
[-verbose]
```

Data Types

```
pins                collection of pins
net                 collection of one net
```

Feedback

```
list_of_files       list
list_of_scenario_configurations list
clock_name          string
name_of_simulator   string
```

Arguments

`-name` *string*

Specifies the name of this subcircuit, which is used to distinguish it from other subcircuits in the same design. The string is used to construct both circuit elements and file names, so it must only contain alphanumeric characters and underscores. With that restriction, you can use any name, but if a clock is being analyzed you should use the name of the clock (if this is unique). Many files are generated based on this name. The name is also given to the output directory, to be created in the current working directory. If no directory by this name exists, one is created. Because many files are created in this directory, you must specify a directory with write permissions and sufficient disk space.

`-clock` *clock_name*

Specifies for which clock domain the analysis should be done. This especially helps to select the appropriate clock path when multiple clocks arrive at pins of a cell in the clock tree.

`-from` *pins*

Specifies the startpoint or startpoints to analyze a circuit. This can be a single driving point of the clock tree, such as the clock source pin, or it can be a set of driver pins in the pre-mesh clock tree.

`-to` *pins*

Specifies a collection of load pins that are driven by the circuit. These define the endpoints of the clock tree paths to be analyzed.

`-net` *net*

Specifies a single net, whose load pins will be used instead of -to as the endpoints of the clock tree paths to be analyzed. Typically this would be a multidriver clock mesh net. Either -to or -net must be specified.

`-simulator` *name_of_simulator*

Specifies which SPICE simulator to use. Supported simulator list: primesim, finesim, hspice and nanosim. The default is nanosim. The simulator you want to use must be available as a working and properly licensed Linux command in your shell path. You may need to adjust the path in your .cshrc or.login file or use "setenv PATH ..." to point the right simulator path before running the command.

Feedback

`-spice_header_files` *`list_of_files`*

Specifies the locations of the SPICE device models of the transistors. SPICE device models are needed for all the transistors. You specify the device models with the file path, and the file paths are copied into the simulator input. If you specify multiple files, they are included in the order specified. Note that file locations are relative to the current working directory (not relative to the new working directory defined by -name.) Absolute file paths may also be used.

`-driver_subckt_files` *`list_of_files`*

Specifies the locations of the subcircuit models of the buffers in the clock mesh tree. The circuit simulator requires a subcircuit model for all the buffers in the clock mesh tree. You specify the subcircuit models with the file path, and the file paths are copied into the simulator input. If you specify multiple files, they are included in the order specified. Note that file locations are relative to the current working directory. Absolute file paths may also be used.

`-configuration` *`list_of_scenario_configurations`*

Customizes the SPICE settings for each scenario and max/min setting to be analyzed. The list can be of any length. Single curly braces are recommended. If Tcl variable substitution is desired, the list can be defined using "..." rather than {...}. Each -scenario_name that is specified is followed by the custom file settings for that scenario. Any or all of the four types of custom file settings may be supplied. For any combinations not specified, the general settings from the *-spice_header_files* and *-driver_subckt_files* options will be used.

The format of the *list_of_scenario_configurations* argument is:

```
-configuration {
      -scenario_name scenario
       [-max_driver_subckt_files max_files]
       [-max_spice_header_files header_max]
       [-min_driver_subckt_files min_files]
       [-min_spice_header_files header_min]
     [-scenario_name scenario]
       [-max_driver_subckt_files max_files]
       [-max_spice_header_files header_max]
       [-min_driver_subckt_files min_files]
       [-min_spice_header_files header_min]
       ...
   }
```

`-spef_input_file_suffix` *`string`*

This option can be used to customize the flow for -create_spice_deck, by replacing the default SPEF parasitics file name with an alternate user-provided SPEF file. For example, this could be used if an external extraction tool is being called rather than native extraction and SPEF generation. The external SPEF file should be generated without a name mapping table: in the IC Compiler tool,

Feedback

use the *write_parasitics -no_name_mapping* command. For each scenario and max/min simulation, the custom SPEF file names should follow this pattern:

`<subcircuit_name>.<scenario_name>.<max/min>.<suffix_name>`

`-rc_include_file_suffix` *`string`*

This option can be used to customize the flow for -create_spice_deck, by replacing the default include file name, for the net parasitics RC data, with the given custom suffix. The default suffix is \'rc.sp\', so for example, \'rc_custom.sp\' could be specified here instead. Users running external extraction tools instead of -extraction can then generate a customized RC parasitics input file for SPICE, and include it in the top-level SPICE deck file with this option, instead of the default.

`-num_simulation_cycles` *`int`*

This option can be used to extend the SPICE simulation duration for the given number of clock periods. This is very useful for insuring that the simulated circuit voltages have stabilized after circuit startup. By default only a single clock period is simulated. A typical value might be 3. It is set to 2 by default if the *time.analyze_subcircuit_include_leakage_power* option is specified and the existing value of number of simulation cycles is less than 2.

`-simulation_time` *`time_in_ns`*

This option is used to specify the simulation time (in nano-second) of spice run (.trans statements). Without this opition, the simulation time is estimated based on clock period.

`-remove_escaped_char`

Controls whether the escaped char is removed from pin name and net name.

`-extraction`

Controls whether the analysis performs native extraction of RC parasitics and writes its own SPEF files for use by the *-create_spice_deck* option. This is Step 1 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

`-create_spice_deck`

Controls whether the analysis will create the top-level SPICE deck files whose names end with *.top.sp, *.rc.sp, and *.meas.cmd. The *.rc.sp file describes the net RC parasitics in native SPICE format, and is by default created here by reading in the SPEF files generated by the -extraction step. The *.top.sp file is the top-level SPICE command file. The *.meas.cmd file defines to SPICE how to measure arrival and transition times at the pins of the clock tree. This is Step 2 of the 5-step analysis process. If none of the five flow-control options

Feedback

are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

`-run_simulation`

Controls whether the analysis will run the SPICE simulation for each active scenario and max/min setting. The -simulator option specifies which SPICE tool is to be used. The SPICE measurement output files from this step are inputs to the -write_annotation step. This is Step 3 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

`-write_annotation`

Controls whether the analysis will create *.tcl timing annotation files for the clock tree, based on reading in the SPICE measurement output files from -run_simulation. These files define annotated transition time and arc delay for the analyzed portions of the clock tree. For multidriver clock mesh nets, they also apply set_disable_timing to disable all except one of those drivers. The annotated net arc delays are then defined from the one remaining driver only. This is Step 4 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

`-apply_annotation`

Controls whether the analysis will source the *.tcl annotation files from -write_annotation, causing the set_disable_timing, set_annotated_delay, and set_annotated_transition constraints to be applied to the clock tree. This is Step 5 of the 5-step analysis process. If none of the five flow-control options are specified, by default all 5 steps will be run. If any of those 5 options are specified, then only the named steps will run.

`-include_power_analysis`

Annotates power measurement from spice simulation into the design. If this option is specified, it appends .meas statements to the *.meas.cmd files which measure the average power of each cell instance in the spice netlist. It also appends set_annotated_power command in the *.tcl annotation files from -write_annotation. These commands annotate the measured power back into the design. By default, the switching power and leakage power are not annotated separately. With the *time.analyze_subcircuit_include_switching_power* app-option turned on, the .meas statements for power analysis written in the *.meas.cmd file are modified to consider the switching power component as well. To get the leakage power of the cells, the app-option *time.analyze_subcircuit_include_leakage_power* needs to be enabled. With this option turned on, the leakage component of power is subtracted from the

Feedback

internal power, and the set_annotated_power command reports the internal and leakage power separately, under -internal and -leakage respectively.

`-max_only`

Generate files, and do spice simulation for max only.

`-min_only`

Generate files, and do spice simulation for min only.

`-distributed_sim_setting` *`string`*

Distributed run setting for spice simulator(hspice / finesim / primesim, nanosim is not supported). The setting by string is passed to simulator command line directly without checking. Do pre-check to make sure it works. For details about the distributed run support (LSF/SGE/GRD/etc), please check user guide of hspice/finesim/primesim.

`-verbose`

Displays the extraction and circuit simulation messages to the console. By default, these messages are redirected into log files in the output directory.

Description

In general, the tool performs timing prediction with static timing analysis. But for some purposes, such as clock meshes, it is necessary or desirable to use circuit simulation. This command generates the necessary files to run a SPICE circuit simulator, invokes the simulator, and reads the output of simulation back into your design as annotation constraints for delay and transition times. The annotation constraints are Tcl files which can be reused in later sessions, as long as the clock tree netlist is unchanged.

Files

Inputs required:

You must have a circuit-level model for each of the buffer gates in your clock tree, and a transistor model for each of the transistors in the circuit models.

Files generated:

This command creates a directory named using the -name string, if it is not already present, and populates it with files for simulation and annotation. These include the circuit files, command files, and measurement files. One of these files is a shell script that is used to invoke the circuit simulator. Simulation produces many output and log files, which also populate the directory. This command then processes those output files and generates an annotation file. This file can be sourced into your design, to update the delays and transition times of your subcircuit to match the circuit simulation results.

Feedback

Limitations

The subcircuit to be is analyzed is modeled as being driven by a single clock waveform signal. That signal is applied at the pin or pins named by -from. A typical usage is to name the clock source pin using -from.

If you want to analyze a set of mesh drivers whose inputs are not yet connected, you can do this using the *-from* option by listing all the mesh driver input pins. For the purpose of simulation, these are all driven in parallel, with no skew among them. This type of simulation is only for early exploration, before the clock tree in the fanin of the mesh drivers has been designed.

Buffers that are "shorted together" in a mesh or other structure are supported. The resistance and capacitance of the mesh is determined by extraction, and is expressed in a SPEF parasitic data file. The SPEF file is generated natively by default, but manual use of external extraction tools such as StarRC is supported by the customized-flow options, which allow users to call an external tool with their own scripting, and then bring the resulting SPEF or other parasitic model files into the SPICE simulation flow.

The underlying circuit simulator is not case-sensitive, so elements "buff_27" and "BUFF_27" are indistinguishable, and the design must not contain both names. For similar reasons, circuit elements should not contain the dot character ".".

The loads of the clock tree endpoints (flip-flops or latches) are modeled by lump capacitance, not by active transistor models, since the outputs of those gates are not part of the simulation. If this operation is done before the signal nets have been routed, which would normally be the case, then final gate placement, routing geometry and detailed placement might not match the geometry in the final chip. There is no modeling of IR drop in the power or ground wires. The actual VSS and VDD used for each buffer gate is assumed to be static and is determined before simulation starts.

For more information on simulation see the documentation for Hspice, Finesim, and Nanosim.

Multicorner-Multimode Support

This command works on all active scenarios.

Examples

In the following example, a clock tree called clk1 has been implemented with a set of specified library references to be used as buffers, driving a clock mesh net called mesh_net. This causes a new directory named clk1 to be created, containing the simulation and annotation files for the specified clock tree. The endpoints of the analyzed tree are the load pins of mesh_net.

After this command has been run, the *report_timing* command reflects the delays and transitions observed in the circuit simulation, if the -path_type full_clock_expanded reporting option is used to show the annotated arc delays and transitions in the clock

Feedback

tree. This example uses hspice as the simulator. Note: If internal pins of cells are included in the clock mesh, the analyze_subcircuit command will exclude these pins from the simulation and issue a TIM-131 message since these pins are not accessible in the simulator subcircuit definition.

```
prompt> analyze_subcircuit -name clk1 \\
   -from clk1_source_pin -net mesh_net \\
   -simulator hspice \\
   -spice_header_files original/models.sp \\
   -driver_subckt_files {original/drivers.sp extra_cells.sp}
```

---

analyze_thermal

Performs the targeted thermal analysis.

Syntax

status *analyze_thermal*

```
[-scenarios scenario_list]
```

Data Types

```
fIscenario_list             string
```

Arguments

`-scenarios` *scenario_list*

Specifies scenarios to do MCMM thermal analysis.

Description

Performs the targeted thermal analysis.

There are several application options that can be used by the *analyze_thermal* command:

- Specifies where to save the thermal analysis results.

  ```
  For example:
  prompt> set_app_options -name thermal.database -value THERMAL_DATABASE
  ```

Feedback

- Specifies the thermal engine.

  For example:
  ```
  prompt> set_app_options -name thermal.engine -value helios
  ```

  - Specifies the grid resolution for the thermal engine.

    For example:
    ```
    prompt> set_app_options -name thermal.grid_resolution -value {10
     20}
    ```

    - Specifies the heat transfer rate to the design boundary.

      For example:
      ```
      prompt> set_app_options -name thermal.heat_transfer_rate
       -value {10000 0}
      ```

      - Specifies the metal profile.

        For example:
        ```
        prompt> set_app_options -name thermal.metal_profile -value M
        ETAL_PROFILE
        ```

        - Specifies the power profile.

          For example:
          ```
          prompt> set_app_options -name thermal.power_profile
           -value POWER_PROFILE
          ```

          - Specifies the tech file.

            For example:
            ```
            prompt> set_app_options -name thermal.tech_file -value
             TECH_FILE
            ```

Examples

The following example performs a basic thermal analysis:

```
prompt> set_app_options -name thermal.tech_file -value TECH_FILE
prompt> set_app_options -name thermal.power_profile -value POWER_PROFILE
prompt> set_app_options -name thermal.metal_profile -value METAL_PROFILE
prompt> set_app_options -name thermal.database -value THERMAL_DATABASE
prompt> analyze_thermal
```

See Also

---

analyze_timing_correlation

Analyzes timing correlation with the PrimeTime tool.

Syntax

status *analyze_timing_correlation*

```
-work_dir dir_name
-pt_exec_path filename
[-scenarios scenarios_list]
[-delay_calculation_style zero_interconnect | auto]
[-si_enable_analysis true | false]
[-use_ptsi true | false]
[-waveform_analysis_mode disabled | full_design]
[-enable_ccs_rcv_cap true | false]
[-pba_mode pba_mode]
[-overwrite_work_dir]
[-clear_work_dir]
[-save_pt_session]
[-use_pt_save_session]
[-disable_compatibility_settings]
[-enable_compatibility_settings]
[-pass_rate_threshold integer ]
[-pt_search_path paths_list ]
[-script_only]
[-pt_pre_link_script filename ]
[-pt_post_link_script filename ]
[-pt_user_script filename ]
```

Feedback

```
[-verbose]
[-nworst integer]
```

Data Types

```
dir_name            string
filename            string
scenarios_list      list
pba_mode            string
paths_list          list
```

Arguments

`-work_dir` *`dir_name`*

Specifies working directory used to store all intermediate files which could be generated by analyze_timing_correlation. The files includes the design-files like netlist/constraints/parasitics, per-scenario Tcl-scripts and timing-data.

`-pt_exec_path` *`executable_path`*

Specify the PrimeTime executable image used for correlation. For example, /global/apps/pt_2015.06/bin/pt_shell

`-scenarios` *`scenarios_list`*

Specify which scenarios to analyze. By default, all scenarios are analyzed.

`-delay_calculation_style zero_interconnect | auto`

Controls the type of delay calculation performed during timing correlation analysis. When not specified, the tool uses the value of the *time.delay_calculation_style* application option.

Valid values are *zero_interconnect* and *auto*. When specifying *zero_interconnect* the tool infers that both signal integrity and waveform analysis are to be disabled, unless explicitly specified.

`-si_enable_analysis true | false`

Controls whether signal integrity is considered during timing correlation analysis. When not specified, the tool uses the value of the *time.si_enable_analysis* application option. Setting this value to true implies that timing windows are enabled.

Valid values are *true* and *false*.

`-use_ptsi true | false`

Controls whether SI analysis uses PTSI engine or Native SI engine. Default value is true -- that is using PTSI engine in doing timing correlation with PT. Valid values are *true* and *false*.

Feedback

To use native SI in correlation: set -use_ptsi false and -si_enable_analysis true
To disable SI in correlation: set -use_ptsi false and -si_enable_analysis fase

`-waveform_analysis_mode disabled | full_design`

When not specified, the tool uses the value of the *time.delay_calc_waveform_analysis_mode* application option.

Valid values are *disabled* and *full_design*.

`-enable_ccs_rcv_cap true | false`

Specifies whether or not the Composite Current Source (CCS) receiver capacitance model is enabled. When not specified the tool uses the value of the *time.enable_ccs_rcv_cap* application option.

Valid values are *true* and *false*.

`-pba_mode pba_mode`

Specifies whether to perform path-based analysis or graph-based analysis The default is to perform graph-based analysis.

Valid values are *none*, *path* and *exhaustive*.

`-overwrite_work_dir`

Initially overwrite the existing work_dir directory.

`-clear_work_dir`

Overwrite existing work_dir upon command completion.

`-save_pt_session`

Save PrimeTime-Sessions and store it under '-work_dir' for later use.

`-use_pt_save_session`

Reuse existing PrimeTime-save-session stored under '-work_dir'.

`-disable_compatibility_settings`

Disables correlation changes to timer settings.

When you use this option, the command uses the current tool timing context during correlation analysis. This is not recommended for the best alignment with the PrimeTime tool.

`-enable_compatibility_settings`

Enables correlation changes to tool timer settings.

Feedback

When you use this option, the command modifies the timing context during correlation analysis to provide the best alignment. This is recommended for the best alignment with the PrimeTime tool.

`-pass_rate_threshold` *`integer`*

threshold criteria for correlation measurement, the default is 3. By default, 0.5 is used when delay_calculation_style equals 'zero_interconnect'.

`-pt_search_path` *`paths_list`*

Additional search_path used to resolve linked-libraries in PrimeTime. For example, '-pt_search_path {path1 path2 path3...}'.

`-script_only`

Write the design collateral and setup Tcl script files only.

`-pt_pre_link_script` *`script_path`*

Tcl script file to be sourced before design has been linked in PrimeTime.

`-pt_post_link_script` *`script_path`*

Tcl script file to be sourced after design has been linked in PrimeTime.

`-pt_user_script` *`script_path`*

Specifies a user-defined PrimeTime script for correlation.

By default, the command generates the design files for the PrimeTime runs based on the current tool settings.

If you use this option, the command uses the specified PrimeTime script for the correlation report.

The command ignores this option if you use the *-pt_pre_link_script* or *-pt_post_link_script* option.

`-verbose`

Show more detail information.

`-nworst integer`

Specifies how many timing endpoints to report in verbose analysis. By default, 5 endpoints are reported.

Description

The *analyze_timing_correlation* command generates a correlation report between this tool and the PrimeTime tool. The report based on slack's end points only.

Feedback

By default, the command performs the following tasks:

1. Generates QoR-compatible design files for the PrimeTime tool based on the current tool settings for each scenario.
2. Invokes the PrimeTime tool to collect the PrimeTime timing data.
3. Collects the timing data from this tool.
4. Generates the correlation report.

Multicorner-Multimode Support

By default, this command applies to all scenarios.

Examples

The following example uses the PrimeTime image located at /bin/pt_shell to generate a correlation report. The intermediate data is stored in a subdirectory named tmp.

```
prompt> analyze_timing_correlation -work_dir tmp \\
   -pt_exec_path /bin/pt_shell -overwrite_work_dir -save_pt_session
```

---

annotate_trace

Control annotation of traced command execution to the shell output.

Syntax

annotate_trace [-start|-stop] [-profile profile_annotation_type] [-log log_string] [-quiet]

string *log_string* string *profile_annotation_type*

Arguments

`-start`

This option is mutually exclusive with -stop. The option starts the annotation of traced command execution to the shell output. Each executed command string is annotated to the output prepended with ";## ".

Feedback

`-stop`

This option is mutually exclusive with -start. This option stops annotation of traced command execution to the shell output.

`-profile` *`profile_annotation_type`*

This option selects the profile data output behavior for command annotation. This option is only meaningful when given with the -start option. The argument is one of: on, with_start, off. The /fIon/fP value starts annotation with profile data output enabled in the default mode which is to output the data only at the end of a command invocation. The data is output only if the delta values from the beginning of the command invocation meet or exceed the thresholds set for each of the reported metrics. The /fIwith_start/fP value starts annotation with profile data output both at the beginning and at the end of a command invocation. The profile data is output at the beginning irregardless of any thresholds since delta values cannot be calculated at the beginning of the invocation. The profile data output at the end of command invocation is controlled by thresholds. The /fIoff/fP value disables profile data output. If profile data annotation is enabled but profile metric gathering has not been enabled with set_trace_option, all profile metrics are auto-enabled. If omitted, annotation is started without profile data output.

`-log` *`log_string`*

This option outputs the given log_string to the shell output prepended with ";## ". If the given string contains newline characters, each line is prendended with ";## ".

`-quiet`

If given, this option causes the command to ignore error conditions such as an attempt to log a comment string before annotation is started. The command will exit quietly when it encounters an error condition.

Description

The *annotate_trace* command performs operations related to annotating traced command execution to the shell output. If the application creates an output log, the annotation is made also to the output log. The command strings which are annotated to the output are those that are traced for creating a traced command replay log.

The *annotate_trace* with no options will report on the current status of annotation: on or off.

Examples

The following example starts annotation of executed commands to the output. Then the command is invoked again with no options to report on the status.

Feedback

```
prompt> annoate_trace -start
prompt> annoate_trace
on
```

The following example configures profile metrids, then starts annotation of executed commands to the output along with the profile data.

```
prompt> set_trace_topion -profile all
prompt> set_trace_topion -memory_threshold 10
prompt> set_trace_topion -cpu_threshold 0
prompt> annotate_trace -start -profile with_start
```

---

append_to_collection

Adds objects to a collection and modifies a variable.

Syntax

collection *append_to_collection* [-dict *dict_var*]

```
[-unique]
var_name
object_spec
```

Data Types

var_name	variable referencing a collection
dict_var	variable referencing a dict
object_spec	list

Arguments

`-unique`

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

var_name

Specifies a variable name. The objects matching *object_spec* are added into the collection referenced by this variable.

Feedback

`-dict` *`dict_var`*

Specifies a variable name referencing a dict object. When this is specified the *var_name* argument specifies the key in the dict to update.

`object_spec`

Specifies a list of named objects or collections to add.

Description

The *append_to_collection* command allows you to add elements to a collection. This command treats the variable name given by the *var_name* option as a collection, and it appends all of the elements in *object_spec* to that collection. If the variable does not exist, it is created as a collection with elements from the *object_spec* as its value. If the variable does exist and it does not contain a collection, it is an error.

Alternatively this command may also update a value in a dict. When *-dict* is specified the *dict_var* is treated as a dict and the key specified by *var_name* is updated. If the dict variable is unset the dict is created. If the value referenced by the variable is not a dict it is an error.

The result of the command is the collection that was initially referenced by the *var_name* option (or dict key value), or the collection created if the variable did not exist.

The *append_to_collection* command provides the same semantics as the common use of the *add_to_collection* command; however, this command shows significant improvements in performance.

An example of replacing the *add_to_collection* command with the *append_to_collection* command is provided below. For example,

```
set var_name [add_to_collection $var_name $objs]
```

Using the *append_to_collection* command, the command becomes:

```
append_to_collection var_name $objs
```

Updating a key in a dictionary:

```
append_to_collection -dict drivers $pinName $newDrivers
```

The *append_to_collection* command can be much more efficient than the *add_to_collection* command if you are building up a collection in a loop. The arguments of the command have the same restrictions as the *add_to_collection* command. For more information about these restrictions, see the *add_to_collection* man page.

Feedback

Examples

The following example from PrimeTime shows how a collection can be built up using the *append_to_collection* command:

```
pt_shell> set xports
Error: can't read "xports": no such variable
        Use error_info for more info. (CMD-013)
pt_shell> append_to_collection xports [get_ports in*]
{"in0", "in1", "in2"}
pt_shell> append_to_collection xports CLOCK
{"in0", "in1", "in2", "CLOCK"}
```

---

apply_clock_gate_latency

Annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the *set_clock_gate_latency* command.

Syntax

status *apply_clock_gate_latency*

Arguments

The *apply_clock_gate_latency* command has no arguments.

Description

The *apply_clock_gate_latency* command annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the *set_clock_gate_latency* command.

Use this command to manually annotate clock-latency values specified by the *set_clock_gate_latency* command to existing clock-gating cells.

The tool only annotates the latency value on the clock pin of a cell (clock gate or register) whose stage is N and whose clock domain is *clk*, if the *set_clock_gate_latency -stage N* was explicitly used for the clock domain. The tool never overwrites latency values on pin objects that are annotated by the *set_clock_latency command*, but it can overwrite values

Feedback

that were annotated due to the *set_clock_gate_latency* command or by optimizations that were enabled by the application option *compile.clockgate.physically_aware*. Latency annotation is only supported for flip-flops and clock gates. The tool does not annotate macro cell pins.

To remove annotated latencies that were specified using the *set_clock_gate_latency* command, use the *reset_clock_gate_latency* command.

To remove the clock gate latency settings that were specified by the *set_clock_gate_latency* command in the current scenario, use the *set_clock_gate_latency -reset* command.

To report the clock gate latency settings that were specified by the *set_clock_gate_latency* command, use the *report_clock_gate_latency* command.

Multicorner-Multimode Support

The actual clock latency annotation performed during the execution of *compile* or *apply_clock_gate_latency* commands is done for all the scenarios for which a clock latency value is available.

---

apply_power_model

Apply a power model which describes the power intent of a reference library cell to instances.

Syntax

```
string apply_power_model
[power_model_name]
[-elements instance_names]
[-supply_map supply_map_list]
[-port_map port_map_list]
[-parameters param_map_list]
[-all_hard_macros]
```

Data Types

```
power_model_name string
instance_names   list of instances
```

Feedback

```
supply_map_list  list of {power_model_supply_set
 current_scope_supply_set}
port_map_list    list of {power_model_supply/logic_port
 current_scope_supply/logic_net}
param_map_list   list of {power_model_parameter parameter_value}
```

Arguments

power_model_name

Specifies the name of the power model to be applied. The name should be a simple (non-hierarchical) name.

The applied power model is searched in this descending order of preference:

```
1. Power models defined in the current scope.
2. Power models defined in any direct ancestor scope: the closest
 the better.
3. Power models defined in user power model library. Please see
 app options
mv.upf.power_model_search_path(3) and
 mv.upf.power_model_library(3).
4. Power models defined in any scope.
```

-elements *instance_names*

Specifies a collection of cells that this power model should be applied to.

If this option is not specified, the power model will be applied to all cells in and under the current scope whose reference library cells match those specified in the power model (i.e. library cells listed in *-for* option of the *define_power_model* command).

-supply_map *supply_map_list*

Specifies the mapping of supply sets in the power model to supply sets in the current scope. For example:

```
-supply_map {{model_vdd top_vdd} {model_vss top_vss}}
```

-port_map *port_map_list*

Specifies the mapping of supply/logic ports in the power model to supply/logic nets in the current scope. For example:

```
-port_map {{model_supply_port top_supply_net} {model_logic_port
 top_logic_net}}
```

-parameters *param_map_list*

Specifies the mapping of parameters in the power model to actual parameter values. For example:

```
-parameters {{model_param1 "value_1"} {model_param2 "value_2"}}
```

Feedback

-all_hard_macros

Apply power models to all hard macro cells under the current scope with matching power model, i.e., the macro lib cell is included in the *-for* option of the *define_power_model* command, or the power model name is the lib cell name.

power_model_name must not be provided and no other options can be specified.

Description

The apply_power_model command binds the power_model_name to the cell instances specified by the -elements option. The associated parameter binding specified via the -parameters option allows objects within the environment to be bound to parameters defined within the power model. Not all parameters within the power model need to be bound to objects in the environment and parameters that are not bound shall retain their default values during run time.

The apply_power_model command sets the scope to each of the specified set of instances, referred to as the instance scope, and then executes the set of UPF commands in the power model power_model_name. Upon return, the current scope is restored to the scope in which the command was invoked.

Examples

The following example applies a power model to two macro cells:

```
prompt> define_power_model MODEL -for {macro_lib_cell} {
  create_supply_set SS_macro
  create_supply_set SS_macro_ao
  create_supply_port VDD_macro
  create_supply_port VSS_macro
}
prompt> create_supply_set SS_top
prompt> create_supply_set SS_top_ao
prompt> create_supply_net VDD_top
prompt> create_supply_net VSS_top
prompt> apply_power_model MODEL -elements {u1/macro u2/macro}
                                -supply_map {{SS_macro SS_top}
 {SS_macro_ao SS_top_ao}}
                                -port_map {{VDD_macro VDD_top} {VSS_macro
 VSS_top}}
```

The following example applies a power model to all instanced cells of lib_cell in or under the current scope. Power domain PD_macro will be created in each of the macro cells:

```
prompt> define_power_model MODEL -for {lib_cell} {
  add_parameter DOMAIN -default domain -description "top power domain in
 model"
  create_supply_net VDD
  create_supply_net VSS
```

Feedback

```
  create_supply_set SS -function {power VDD} -function {ground VSS}
  create_power_domain PD_$DOMAIN -supply {primary SS} -include_scope
}
prompt> apply_power_model MODEL -parameters {{DOMAIN macro}}
```

The following example applies power model MODEL_A to all instantiated cells of lib_cell_A and applies power model lib_cell_B to all instantiated cells of lib_cell_B in or under the current scope:

```
prompt> sh cat ./power_model.upf
define_power_model MODEL_A -for {lib_cell_A} { create_power_domain PD_A }
prompt> sh cat ./lib_cell_B.upf
define_power_model lib_cell_B { create_power_domain PD_B }
prompt> set_app_options -as_user_default \\
   -name mv.upf.power_model_search_path -value "."
prompt> set_app_options -as_user_default \\
   -name mv.upf.power_model_library -value "power_model.upf
 lib_cell_B.upf"
prompt> apply_power_model -all_hard_macros
```

See Also

---

apropos

Searches the command database for a pattern.

Syntax

string *apropos*

```
[-symbols_only]
pattern
```

Data Types

```
pattern      string
```

Feedback

Arguments

`-symbols_only`

Searches only command and option names.

`pattern`

Searches for the specified *pattern*.

Description

The *apropos* command searches the command and option database for all commands that contain the specified *pattern*. The *pattern* argument can include the wildcard characters asterisk (*) and question mark (?). The search is case-sensitive. For each command that matches the search criteria, the command help is printed as though *help -verbose* was used with the command.

Whereas *help* looks only at command names, *apropos* looks at command names, the command one-line description, option names, and option value-help strings. The search can be restricted to only command and option names with the *-symbols_only* option.

When searching for dash options, do not include the leading dash. Search only for the name.

Examples

In the following example, assume that the *get_cells* and *get_designs* commands have the *-exact* option. Note that without the *-symbols_only* option, the first search picks up commands which have the string "exact" in the one-line description.

```
prompt> apropos exact
 get_cells            # Create a collection of cells
   [-exact]               (Wildcards are considered as plain characters)
   patterns               (Match cell names against patterns)

 get_designs          # Create a collection of designs
   [-exact]               (Wildcards are considered as plain characters)
   patterns               (Match design names against patterns)

 real_time            # Return the exact time of day

prompt> apropos exact -symbols_only
 get_cells            # Create a collection of cells
   [-exact]               (Wildcards are considered as plain characters)
   patterns               (Match cell names against patterns)

 get_designs          # Create a collection of designs
   [-exact]               (Wildcards are considered as plain characters)
   patterns               (Match design names against patterns)
```

Feedback

- help

---

as_collection

Find a collection by name

Syntax

string *as_collection* [-check] *collection1*

```
string collection1
```

Arguments

`-check`

Return 1 if collection1 is a collection

collection1

The collection to convert

Description

This command looks up a string value and returns it as a collection it the collection is still live. All other values are passed through this command unmodified.

This command is also provides a simple way to check if the input is a collection.

Examples

Check if a value is a collection:

```
shell> as_collection -check [get_cells]
1
shell> as_collection -check hello
0
```

See Also

- collections
- foreach_in_collection

---

assign_3d_interchip_nets

Derives logical connections between bumps and drivers that have the shortest wirelength between them.

Feedback

Syntax

status *assign_3d_interchip_nets*

```
[-bumps cell_list]
[-nets net_list]
[-matching_types matching_types]
[-set_port_terminals incremental | all]
[-bond_pads terminals]
[-pseudo_bumps pseudo_bump_lit]
[-bump_regions bump_region_list]
[-no_port_punching]
[-include_pg_nets]
[-port_naming_style naming_style]
[-net_naming_style naming_style]
```

Data Types

```
cell_list       collection
net_list        collection
terminal_list   collection
matching_types  list
pseudo_bumps    list
bump_regions    list
naming_style     string
```

Arguments

`-bumps cell_list`

Specifies the bumps for logical connection. By default, all bumps in the design are considered. If only one bump is selected, its center-aligned bump is selected as a pair.

`-nets net_list`

Specifies the nets for logical connection. By default, all top-level nets in design are available.

`-matching_types matching_types`

Specifies the matching types used to categorize different assignment groups. By default, all matching types are considered. If there is no matching type defined in the design, all bumps and drivers are considered in wirelength calculation.

`-set_port_terminals incremental | all`

Specifies the strategy to update the terminals(preferred_pin) for ports. Default value is *incremental*.

Feedback

- *incremental*: only set terminals(preferred_pin) to the ports that have not been set and can be set with preferred_pin.
- *all*: set terminals(preferred_pin) to all ports no matter if they have terminals(preferred_pin) or not.

`-bond_pads` *`terminal_list`*

Specifies the bond pads for logical connection. By default, all bond pads in the design are considered. If only one bond pad is selected, its center-aligned bond pad is selected as a pair.

`-pseudo_bumps` *`pseudo_bumps`*

Specifies the pseudo bumps for logical connection. By default, all pseudo bumps in the design are considered. If only one pseudo bump is selected, its center-aligned pseudo bump is selected as a pair.

`-bump_regions` *`bump_regions`*

Specifies the bump regions for logical connection. By default, all pseudo bumps of all bump regions in the design are considered. If only one bump region is selected, its center-aligned pseudo bumps in another bump region is selected as a pair.

`-no_port_punching`

Do not allow port punching.

`-include_pg_nets`

Include PG nets for free net assignment.

`-port_naming_style` *`naming_style`*

Specify the naming style of new created ports. The option string contains the desired format of the new ports. The possible keywords are:

- *%s*: the original name • *%d*: integer to uniquify the port • *%layer*: the layer of the port will be created on • *%contactdie*: the die of the port goes to

The value can also include a desired fixed string. The string that begins with % but doesn't match the keywords will be ignored. If the port goes to external world(package), the keyword *%contactdie* will be mapped to "C4" in the port's name. If the value doesn't include any valid keyword, the option won't work. If %d is not specified and the new name is not unique, a underscore and uniquifying integer will be added.

Feedback

`-net_naming_style` *`naming_style`*

Specify the naming style of new created nets. The option string contains the desired format of the new nets. The possible keywords are:

- *%s*: the original name • *%d*: integer to uniquify the net • *%layerpair*: the layers of the ports on the nets • *%diepair*: the two dies of the net connect to, the format is topdie_botdie

The value can also include a desired fixed string. The string that begins with % but doesn't match the keywords will be ignored. If the value doesn't include any valid keyword, the option won't work. If %d is not specified and the new name is not unique, a underscore and uniquifying integer will be added.

Description

This command builds logical connections between bumps and drivers with the shortest wirelength. The net for assignment should have the driver-pin pair connected. Meanwhile, the bump pin should be free for assignment. If there are one or more bump pins on the net, the net will be skipped. You can use the *disconnect_3d_bumps* command before performing net assignment or specifying the correct net for assignment. Hierarchy bumps are supported.

Examples

The following example derives the logical connection between drivers on the net sip_data_a[19] with the bump pair {mini_cpu_chip_inst/BUMP_RING9 addmult_sip_inst/BUMP_RING9}.

```
prompt> assign_3d_interchip_nets -nets sip_data_a[19] \\
   -bumps {mini_cpu_chip_inst/BUMP_RING9 addmult_sip_inst/BUMP_RING9}
```

See Also

---

assign_bump_objects

Syntax

collection *assign_bump_objects*

Feedback

```
target
-nets collection
-ports collection
[-sources collection]
[-fanout_threshold integer]
[-limit double]
[-radius distance]
[-keep]
[-quiet]
[-verbose]
```

Data Types

```
target       collection
collection   collection
integer      integer
double       double
distance     distance
```

Arguments

target

Specify a collection of bump regions or pseudo bumps or flip_chip_pad cells or bond_pad terminals.

-nets *collection*

Specify a collection of nets, net buses, bundles, or supernets. It is mutually exclusive with *-ports* option.

-ports *collection*

Specify a collection of ports or port buses. It is mutually exclusive with *-nets* option.

-sources *collection*

Specify a collection of cells to derive the bumps assignment from.

-fanout_threshold *integer*

If net has more pins then specified fanout threshold, it is being skipped. The default value is 100,000 pins.

-limit *double*

Ratio of available bumps to consider to assign to the objects: Range: 0.01 to 1.

-radius *distance*

Limit the available bumps within specified radius to assign to the objects.

Feedback

`-keep`

Specify to keep the existing net assignment. Useful in the cases when there is a net pattern defined on a region to fill up the empty gaps between pre-assigned nets.

`-quiet`

Suppresses all warnings. Syntax error messages are not suppressed.

`-verbose`

Prints extra informations about the assignment process.

Description

Assign the nets or ports to the pseudo bumps, bump cells or bond pads, so that total Mangattan distance to the pins of the nets is minimal. The command returns the collection of assigned objects.

Examples

The following example set the nets A* to pseudo_bumps of a region BR.

```
prompt> assign_bump_objects [get_bump_regions BR] -nets [get_nets A*]
```

See Also

- assign_redundant_bumps
- get_pseudo_bumps
- get_bump_regions

---

assign_feedthrough_supply

Assigns related supplies for feedthrough ports of a given net or net connected to a given pin.

Syntax

status *assign_feedthrough_supply*

```
[-net nets]
[-pin pins]
[-verbose]
[-output_report]
[-failure_report]
```

Data Types

```
nets     collection
pins     collection
```

Feedback

Arguments

`-net`

Generates the related supplies for the feedthrough pins connected to the given nets.

`-pin`

Generates the related supplies for the given feedthrough pins and feedthrough pins on the net connected to these pins.

`-verbose`

Report driver of net which *assign_feedthrough_supply* failed to propagate and its failure reasons.

`-output_report`

Optional argument to specify file name for output report.

`-failure_report`

Optional argument to specify file name for failure report.

Description

The *assign_feedthrough_supply* command determines the best supplies to use as related supplies for the feedthrough ports on a given net or pin. The supplies are determined with the goal of minimizing the use of dual rail cell buffer/inverters in feedthrough domains.

You must specify either *-net* or *-pin* option.

When the command runs it reports the following information messages:

- The name of the output report (*MV-1055*)
- The name of the report for failed nets (*MV-1051*)
- The number of nets correctly processed by the command (*MV-1056*)
- The number of nets which the command failed to process (*MV-1057*)
- The number of nets which command skipped (*MV-1052*)

=== Global net split concept ===

For command context, we refer global net to the net which goes from *driver* to *loads*. The global net can be split if there is a soft macro port with user defined *set_port_attributes*. For example, in the following global net:

Driver: in Port: MID/in Port: MID/out Port: BOT/in Port: BOT/out Load: out

Feedback

If *MID* is a soft macro cell and *MID/out* has user defined *set_port_attributes*, then the global net is split into two nets:

Driver: in Port: MID/in Load: MID/out

Driver: MID/out Port: BOT/in Port: BOT/out Load: out

Those nets are processed independently which means net "in" can fail while the net "MID/out" will finish successfully. If that were the case, the command will have the following result:

- Output report will have the assigned related supply for port MID/out. • Report for failed net will have information about net MID/out with its failure reason. • Message MV-1056 will report assigned supply for 1 net (net MID/out). • Message MV-1057 will report failed to assign 1 net (net in)

=== Behavior with Constant Net ===

To derive driver supply of the constant nets, tool collects all loads supplies plus driver domain primary supply. Only supply nets which are available in the driver domain are considered. The command assigns the supply which creates less dual-rails buffer. If two or more supply nets generate the same result, the solution using driver supply is preferred.

For paths which includes soft macro, if there is a user specified receiver supply on any soft macro port, tool considers the receiver supply as load supply, instead of traversing through to the final load.

=== Output Report ===

By running this command, an output report file is created with the name *assign_feedthrough_supply.report.<design_name>*. The report contains information for each net that was successfully processed by the command. The report starts with the application option section where application options, which can change command behavior, are listed. After that section, each net is reported as a list of physical boundary ports, where each port can show below information (attributes):

- Constant/Undriven: When driver is constant or undriven e.g. *tie cell*, tool reports "Constant/Undriven" instead of port name.
- driver_supply: Port uses driver supply as related supply set. The attribute could appear in any pin.
- receiver_supply: Port uses load supply as related supply set. The attribute could appear in any pin.
- primary_supply: Port uses Power Domain's primary supply as related supply set. The attribute could appear in any pin.
- reference-only: The assigned supply set is not available in block power domain and cannot used for buffering. The attribute could appear in any pin.

Feedback

- soft_macro: The port belongs to a soft-macro cell. The attribute appears in soft macro ports.
- refinable_macro: The port belongs to a refinable-macro cell. The attribute appears in refinable macro ports.
- user_spa: When the attribute is present it indicates the related supply set was assigned by user or *split_contraints* (it is in user section of UPF file). If it is not present, it means the attribute was set by *assign_feedthrough_supply* command (it is in derived section of UPF file). This attribute can only appear on drivers and loads.
- updated: When this attribute is present it means tool changed related supply set of this port for a new one. For example, if the previous value was *SS1* and the new value is *SS2*, the *updated* attribute will be reported. If both were similar (the previous value and new value are *SS1*) or if there is no previous value, the *updated* attribute will not be reported. This attribute can only appear on physical boundary ports.
- dangling: When *mv.hierarchical.propagate_driver_supply_for_empty_design* is enabled, *assign_feedthrough_supply* reports unconnected endpoints as loads. This attribute is meant to differentiate between real loads and unconnected endpoints.

Besides these attributes, the report also shows *feedthrough port level* which is the deep level starting from the driver pin to the reported pin. *Feedthrough port level* for driver pin is not showed in this report and it is assumed to be 0. Below there is an example for output report:

```
-------------------------------------------------
  Application Options for assign_feedthrough_supply:
  -------------------------------------------------
  mv.hierarchical.afs_create_reference_supply: true
  mv.hierarchical.propagate_driver_supply_use_same_driver_receiver: false
  mv.hierarchical.propagate_driver_supply_for_empty_design: true
  mv.hierarchical.propagate_driver_supply_use_soft_macro_domain_primary:
 false
  -------------------------------------------------

  + DRIVER_PIN in: SS0 (driver_supply, primary_supply, user_spa)
    - (Level 1) MID0/in: SS0 (driver_supply)
    - (Level 2) MID0/out: SS0 (driver_supply)
    - (Level 3) MID1/in: SS2 (receiver_supply, primary_supply,
 soft_macro)
    - (Level 4) LOAD_PIN MID1/out: SS2 (receiver_supply, primary_supply,
 soft_macro, user_spa)
    - (Level 3) MID2/in: SS0 (driver_supply, soft_macro)
    - (Level 4) LOAD_PIN MID2/out: SS0 (driver_supply, soft_macro,
 user_spa)
```

In the above example, there is a heterogeneous split fanout from driver *in* to loads *MID1/out* and *MID2/out* where both loads are at the same feedthrough port level.

Feedback

=== Failure Net Report ===

Whenever this command runs, it creates a report named *assign_feedthrough_supply.report.<design_name>.failed*. This file name is always reported using message *MV-1051*.

Similar to output report, it starts with the application option section and reports information for failed nets only. You can check *-verbose report* section to know which errors are classified as *failed*.

For each failed net, it shows following information:

- Failed reason before driver pin:

```
Driver: in
  MV-1061: Net driven by 'in' has Level Shifter Violation. Please, fix
 the violation before continuing.
```

- Report below information for driver, loads and feedthrough ports:

```
Level <feedthrough level> -- <pin name> (attributes)
  Type: <Driver, Feedthrough or Load>
  Pin Direction: <in, out, inout>
  Power Domain: <power domain name>
  Primary Supply: <supply set name>
  Available Supplies: <list of supply nets>
  Physical Block: <block name>
```

where attributes could be one or more of below:

- undriven: If port is a driver but has no real driver. It can only appear on driver ports. • dangling: If port is a dangling load. It can only appear on load ports. • constant: If port is a driver connected to a constant zero or one. It can only appear on driver ports. • soft_macro: If port is a soft_macro port. It can appear on any port. • refinable_macro: If port is a refinable_macro port. It can appear on any port.

Similar to output report, feedthrough port level is also shown but it includes the feedthrough port level for drivers.

Note that the report is always overwritten to have up-to-date information of the last run of *assign_feedthrough_supply*.

Below there is an example of report for failed nets:

```
--------------------------------------------------
  Application Options for assign_feedthrough_supply:
  --------------------------------------------------
  mv.hierarchical.afs_create_reference_supply: true
  mv.hierarchical.propagate_driver_supply_use_same_driver_receiver: false
  mv.hierarchical.propagate_driver_supply_for_empty_design: true
  mv.hierarchical.propagate_driver_supply_use_soft_macro_domain_primary:
 false
```

Feedback

```
 ------------------------------------------------

 Driver: in
 MV-1061: Net driven by 'in' has Level Shifter Violation. Please, fix
the violation before continuing.

```

=== -verbose report ===

Feedback

Using the *-verbose* option can help you to understand why *assign_feedthrough_supply* failed to process one or more nets. Below are the typical problems:

- Net with bidirectional pins (*MV-1058*): Bidirectional pins are not supported by this command. This message is classified as *skipped*.
- Clock net (*MV-1059*): Clock nets are supported by this command, but they must be present in the list of permitted clock net (see *mv.upf.auto_ls_clock_nets* for more details). This message is classified as *skipped*.
- Analog net (*MV-1060*): Analog nets pins are not supported by this command. This message is classified as *skipped*.
- Level Shifter Violations (*MV-1061*): Tool tries to fix Level Shifter Violations as part of its normal run. However, there are cases where tool cannot solve them. In those cases, *-verbose* option will report *MV-1061*. You can run other commands to get more details about Level Shifter Violations like *check_mv_desing -level_shifter*, *analyze_mv_feasibility -level_shifter*, *analyze_mv_design -level_shifter -through* and *report_mv_path -level_shifter -pin*. This message is classified as *failed*.
- Bump Cell Driver (*MV-1062*): Nets driven by Bump Cells are not supported by this command. This message is classified as *skipped*.
- Undriven nets (*MV-1064*): Undriven nets are only supported if *mv.hierarchical.propagate_driver_supply_for_empty_design* is true. This message is classified as *skipped*.
- Skipped net because there is no feedthrough port to work with (*MV-1065*): Net is skipped since it has no assignable feedthrough ports. This message is classified as *skipped*.
- Skipped net because it has no loads (*MV-1066*): Nets with no loads are only supported if *mv.hierarchical.propagate_driver_supply_for_empty_design* is true. This message is classified as *skipped*.
- Isolation Violations (*MV-1067*): Tool cannot work with net which have isolation violation. They must be fixed before running the command. This message is classified as *failed*.

Examples

The following is an example of the output report generated by *assign_feedthrough_supply*:

```
prompt> set_port_attributes -driver_supply SS3 -ports MID1/out
prompt> assign_feedthrough_supply -pin in
prompt> sh cat assign_feedthrough_supply.report.*

-------------------------------------------------
Application Options for assign_feedthrough_supply:
-------------------------------------------------
mv.hierarchical.afs_create_reference_supply: true
```

Feedback

```
mv.hierarchical.propagate_driver_supply_use_same_driver_receiver: false
mv.hierarchical.propagate_driver_supply_for_empty_design: true
mv.hierarchical.propagate_driver_supply_use_soft_macro_domain_primary:
 false
-------------------------------------------------

Feedback

assign_redundant_bumps

Syntax

collection *assign_redundant_bumps*

```
target
-nets collection
-ports collection
[-sources collection]
[-fanout_threshold integer]
[-limit double]
[-radius distance]
[-keep]
[-quiet]
[-verbose]
```

Data Types

```
target       collection
collection   collection
integer      integer
double       double
distance     distance
```

Arguments

target

Specify a collection of bump regions or pseudo bumps or flip_chip_pad cells or bond_pad terminals.

-nets *collection*

Specify a collection of nets, net buses, bundles, or supernets. It is mutually exclusive with *-ports* option.

-ports *collection*

Specify a collection of ports or port buses. It is mutually exclusive with *-nets* option.

-sources *collection*

Specify a collection of cells to derive the bumps assignment from.

-fanout_threshold *integer*

If net has more pins then specified fanout threshold, it is being skipped. The default value is 100,000 pins.

-limit *double*

Ratio of available bumps to consider to assign to the objects: Range: 0.01 to 1.

Feedback

`-radius` *distance*

Limit the available bumps within specified radius to assign to the objects.

`-keep`

Specify to keep the existing net assignment. Useful in the cases when there is a net pattern defined on a region to fill up the empty gaps between pre-assigned nets.

`-quiet`

Suppresses all warnings. Syntax error messages are not suppressed.

`-verbose`

Prints extra information about the assignment process.

Description

Assign redundant bumps to existing bumps of nets or ports The command returns the collection of assigned objects.

Examples

The following example assigns B* bumps to nets A* as redundant bumps.

```
prompt> assign_redundant_bumps -nets [get_nets A*] [get_cells B*]
```

---

assign_tsv

Assigns the specified TSV (Through Silicon Via) in the TSV list to the specified logical net and pins in the pin list.

Syntax

int *assign_tsv*

```
tsv_list
[-net net]
[-pins pin_list]
[-prefix prefix]
[-force]
```

Feedback

Data Types

```
net       net
pin_list  list
prefix    string
```

Arguments

tsv_list

Specifies the TSV to assign. If a TSV list is specified, the first TSV in the list is the source point for routing. At least one TSV must be specified. This is a required option.

-net *net*

Specifies the net to assign the TSV to. All specified objects are logically connected to the net. If all objects are initially unconnected to any net, a new net will be created with the given prefix that specified with option *-prefix*. If an existing net is already connected to some of the objects, the net will be reused. To avoid user error, the command does not allow two existing nets to be assigned together. This option and the *-pin* option are mutually exclusive.

-pins *pin_list*

Specifies a list of pins to assign to the TSV. This option and the *-net* option are mutually exclusive.

-prefix *prefix*

Specifies a prefix for the name of a new net, if created.

-force

Force the TSV to connect to the specified net.

Description

This command assigns the specified TSV in the tsv_list to the specified logical net and pins in the pin_list.

Examples

The following example assigns the specified TSV.

```
prompt> assign_tsv tsv1
```

---

associate_checkpoint_action

Associates an action with checkpoint names.

Syntax

```
integer associate_checkpoint_action
[-before   {list_of_checkpoint_patterns}]
[-after    {list_of_checkpoint_patterns}]
[-replace  {list_of_checkpoint_patterns}]
[-enable   name_of_action]
[-disable  name_of_action]
```

Data Types

```
list_of_checkpoint_names   list
name_of_action   string
```

Arguments

`-before list_of_checkpoint_patterns`

Specifies that the action should run before all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -after and -replace options.

`-after list_of_checkpoint_patterns`

Specifies that the action should run after all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before and -replace options.

Feedback

`-replace` *`list_of_checkpoint_patterns`*

Specifies that the action should run as a replacement for the Tcl commands wrapped by the eval_checkpoint command. This happens for all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before and -after options.

`-enable` *`name_of_action`*

Specifies the name of the action to enable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -disable option. name_of_action must be an action previously defined with the create_checkpoint_action command.

`-disable` *`name_of_action`*

Specifies the name of the action to disable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -enable option. name_of_action must be an action previously defined with the create_checkpoint_action command. If an action is both disabled and enabled at a checkpoint, the disable setting takes precedence and the action will not run.

Description

This command configures an action to run at one more more checkpoints triggered by the eval_checkpoint command in the flow scripts. Actions are defined in the checkpoint system with the create_checkpoint_action command.

This command has two required options. The first is one of -enable or -disable, which takes the name of the action as its parameter. This option specifies the name of the action being associated, and whether that action should be enabled or disabled for the patterns that will be given with the -before/-after/-replace option. -enable and -disable are mutually exclusive on a single call to associate_checkpoint_action. But multiple calls can be done to this command in sequence to give both enable and disable constraints. The -enable and -disable settings from multiple invocations of associate_checkpoint_action are time-sequenced. For example, enabling an action to run at * (all checkpoints), and then disabling it to run at the 'create_placement' checkpoint will result in that action running at all checkpoints except for 'create_placement'. This is a typical application of the disable option, where an action is enabled to run at multiple checkpoints using a wildcard pattern, but then disabled for one or more specific checkpoints that were matched by that pattern.

The second required option is one of -before, -after, or -replace. This option specifies the timing of the execution of the action, relative to the checkpointed command. Only one of -before, -after, or -replace can be given.

Feedback

- -before indicates that the action should run before the checkpointed command. A typical before action is setting an app option before running a command.
- -after indicates that the action should run after the checkpointed command. A typical after action does some post-command cleanup, like changing constraints.
- -replace indicates that the action should run in place of the checkpointed command. In this case, the action is run but the original Tcl command/s wrapped by eval_checkpoint do not execute. A typical usage of a replace action is to skip execution of a command (by replacing it with nothing), or to modify the options of a command. The 'get_current_checkpoint -command' command can be run inside such a replacement action to get the original command including it's options, so that they can be modified by the action.

Any of the -before, -after, -replace options take a required parameter which is a Tcl list of checkpoint name patterns at which to execute the action. For example, -before "*placement* place_opt_initial_place" specifies that an action should execute before any checkpoint with the name place_opt_initial_place, or with a name that includes the sub-string 'placement'.

Action definitions and associations should not be part of the golden flow scripts for the design or project. They are intended to execute non-default actions that deviate from the standard flow. They are typically included in the ./checkpoint.config.tcl file in your run directory, which is automatically sourced by the checkpoint system.

Examples

Configures the gropto action to run before any *initial_drc checkpoints, to enable GR-based high-fanout synthesis in and place_opt

```
## In ./checkpoint.config.tcl
create_checkpoint_action gropto {
  set_app_options \
-name place_opt.initial_drc.global_route_based \
-value true
}

associate_checkpoint_action -enable gropto -before *initial_drc

## Action will execute before this line in the flow script place_opt.tcl
eval_checkpoint place_opt_to_initial_drc {
place_opt -from initial_place -to initial_drc
}
```

Configures the high_eff_cong action to force high-effort congestion on all create_placement* and refine_placement* checkpoints. get_current_checkpoint -command is used to access and modify the original command options, and the -replace option is used to replace the original command contents. ## In ./checkpoint.config.tcl

Feedback

```
create_checkpoint_action high_eff_cong {
 eval [get_current_checkpoint -command] -congestion_effort high
}

associate_checkpoint_action -enable high_eff_cong \
  -replace "create_placement* refine_placement*"

## Action will execute as a replacement for checkpoints like these in the
 flow scripts
eval_checkpoint create_placement_incr {create_placement -incremental}
eval_checkpoint refine_placement {refine_placement -effort high}
```

---

associate_checkpoint_report

Associates a report with checkpoint names.

Syntax

```
integer associate_checkpoint_report
[-before   {list_of_checkpoint_patterns}]
[-after    {list_of_checkpoint_patterns}]
[-enable   name_of_report]
[-disable  name_of_report]
```

Data Types

```
list_of_checkpoint_names   list
name_of_report   string
```

Feedback

Arguments

`-before` *`list_of_checkpoint_patterns`*

Specifies that the report should run before all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -after option.

`-after` *`list_of_checkpoint_patterns`*

Specifies that the report should run after all checkpoints matching any of the given checkpoint patterns. This option takes a Tcl list of checkpoint name patterns as its parameter. Those names can be simple checkpoint names or include glob-style * wildcard characters. Mutally exclusive with the -before option.

`-enable` *`name_of_report`*

Specifies the name of the report to enable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -disable option. name_of_report must be a report previously defined with the create_checkpoint_report command.

`-disable` *`name_of_report`*

Specifies the name of the report to disable at the matching checkpoint patterns of the -before, -after, or -replace option. Mutually exclusive with the -enable option. name_of_report must be a report previously defined with the create_checkpoint_report command. If a report is both disabled and enabled at a checkpoint, the disable setting takes precedence and the report will not run.

Description

This command configures a report to run at one more more checkpoints triggered by the eval_checkpoint command in the flow scripts. Reports are defined in the checkpoint system with the create_checkpoint_report command.

This command has two required options. The first is one of -enable or -disable, which takes the name of the report as its parameter. This option specifies the name of the report being associated, and whether that report should be enabled or disabled for the patterns that will be given with the -before/-after option. -enable and -disable are mutually exclusive on a single call to associate_checkpoint_action. But multiple calls can be done to this command in sequence to give both enable and disable constraints. The -enable and -disable settings from multiple invocations of associate_checkpoint_action are time-sequenced. For example, enabling a report to run at * (all checkpoints), and then disabling it to run at the 'load_constraints' checkpoint will result in that action running at all checkpoints except for 'load_constraints'. This is a typical application of the disable option, where an action is enabled to run at multiple checkpoints using a wildcard pattern, but then disabled for one or more specific checkpoints that were matched by that pattern.

Feedback

The second required option is one of -before or -after. This option specifies the timing of the execution of the report, relative to the checkpointed command. Only one of -before or -after can be given.

- -before indicates that the report should run before the checkpointed command. A before report is used to measure QoR right before a command executes.
- -after indicates that the action should run after the checkpointed command. An after report is used to measure QoR right after a command executes.

Both the -before and -after options take a required parameter which is a Tcl list of checkpoint name patterns at which to execute the report. For example, -after "*final route_opt*" specifies that an report should execute after any checkpoint with a name ending in 'final', as well as all route_opt checkpoints.

Typically, report are written to files in the ./checkpoint directory, but this is not enforced and you can write reports to any disk location.

Report definitions and associations should not be part of the golden flow scripts for the design or project. They are intended to separate reporting from the flow, such that individual users can customize their reporting needs without touching the golden flow. They are typically included in the ./checkpoint.config.tcl file in your run directory, which is automatically sourced by the checkpoint system.

Examples

Save a block before route_opt for interactive debugging. get_current_checkpoint -name is used to give the block a unique name.

```
## In ./checkpoint.config.tcl
create_checkpoint_report save_block {
 save_block -as checkpoint_[get_current_checkpoint -name]
}

associate_checkpoint_report -enable save_block -before route_opt

## Block will be saved before this line from the route_opt.tcl flow
 script
eval_checkpoint route_opt { route_opt }
```

Generate useful timing reports throughout the flow. Disables timing report generation at the read_constraints checkpoints. Uses the get_current_checkpoint -name and -position commands to give unique names to the reports before or after any checkpoint.

```
## In ./checkpoint.config.tcl
create_checkpint_report timing {
 set name [get_current_checkpoint -name]
 set pos [get_current_checkpoint -position]
 redirect -file ./checkpoint/$name.$pos.qor.rpt { report_qor }
 redirect -append ./checkpoint/$name.$pos.qor.rpt { report_qor -summary }
```

Feedback

```

associate_mv_cells

Associates the UPF strategies to the power management cells in the current design, and reports the correlation between power management cells in the netlist and the UPF strategies.

Syntax

status *associate_mv_cells*

```
[-isolation_cells]
[-level_shifters]
[-retention_registers]
[-power_switches]
[-all]
[-all_blocks | -blocks block_designs]
[-host_options host_option_name]
```

Feedback

Arguments

`-all_blocks`

Associate MV cells for all the child blocks in the current design and the current design itself. This option is mutually exclusive with *-blocks*. Only one of them can be specified at a time.

`-blocks` *`block_designs`*

Specifies the list of child block designs to associate MV cells. This option is mutually exclusive with *-all_blocks*. Only one of them can be specified at a time.

`-host_options` *`host_option_name`*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

`-isolation_cells`

Reports the correlation and discrepancies between isolation cells and isolation strategies.

`-level_shifters`

Reports the correlation and discrepancies between level-shifter cells and level-shifting strategies.

`-retention_registers`

Reports the correlation and discrepancies between retention cells and retention strategies.

`-power_switches`

Reports the correlation and discrepancies between power switches and UPF power-switch strategies.

`-all`

Reports the correlation and discrepancies between all type of power management cells and the strategies.

Description

The *associate_mv_cells* command analyzes the current design and associates existing power-management cells according to the UPF strategies. It also checks and reports the correlation between the power-management cells in the netlist and the corresponding UPF strategies. The checking is based only on the UPF strategies. This command does not check for electrical violations.

If none of the power-management cell types are specified, this command associates all types of the power-management cells in the design.

Feedback

Examples

The following example shows the report from the *associate_mv_cells* command when you do not specify any argument. All types of power-management cells are reported.

```
prompt> associate_mv_cells
prompt>Information: Total 223 power switch cells have been associated.
 (MV-021)
prompt>Information: Total 100 retention cells have been associated.
 (MV-021)
prompt>Information: Total 40 isolation cells have been associated.
 (MV-021)
prompt>Information: Total 50 level shifter cells have been associated.
 (MV-021)
1
```

---

associate_performance_via_ladder

Associate via rules on lib_pins.

Syntax

status *associate_performance_via_ladder*

```
-lib_pins lib_pin_names
-output association_file_name
-reset
-dont_use
```

Data Types

```
lib_pin_names          string or collection of lib_pins
association_file_name  string
```

Arguments

`-lip_pins` *lib_pin_names*

Specifies lib_pin_names which need performance via ladder candidates.

`-output` *association_file_name*

Specifies output via ladder association file name. [Default: auto_perf_via_ladder_association.tcl]

Feedback

`-reset`

Reset existing via ladder candidates from lib_pins

`-dont_use`

Allow via_ladder candidates on lib_cells with dont_use attr

Description

This command generates association file for via rules on each lib_pin through set_via_ladder_candidate. This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

Examples

The following is the usage examples.

```
prompt> associate_performance_via_ladder
1

prompt> associate_performance_via_ladder -lib_pins [get_lib_pins
 */*D12*/Z]
1
```

---

associate_supply_set

Associates a supply set or supply set ref to a supply set handle. The supply set handle should be a pre-defined supply set for the power domain. User defined supply sets cannot be used as supply set handle.

Syntax

```
string associate_supply_set
[-handle {supply_set_handle}*]
supply_set_ref
```

Feedback

Data Types

```
supply_set_ref  string
supply_set_handle string
```

Arguments

`-handle {supply_net_handle}*`

Specifies the name of the predefined supply set of the given domain. This should be the name constructed from the power domain name or strategy name. Predefined *supply_set_handles* for the power domain include: *domain_name.primary*, *domain_name.default_isolation* and *domain_name.default_retention*. This argument is required.

`supply_set_ref`

Specifies the supply set to be associated with the specified handle.

Description

The *associate_supply_set* command associates a supply set with a power domain or strategy handles. Handles are names rooted in the active scope. Handles should be predefined supply sets for the power domain. If shall be an error if : 1) A supply set handles are already associated with a supply set. 2) The associations of handles to supply sets form a loop of associations.

Examples

The following example associates a supply set named SS1 to PD.primary

```
prompt> associate_supply_set SS1 -handle PD.primary
```

---

attach_drc_error_data

Attaches a DRC error data object to the current block.

Syntax

```
status attach_drc_error_data
-name name
drc_error_data
[-keep]
```

Feedback

Data Types

name	string
drc_error_data	collection

Arguments

`-name` *name*

Specifies the name for the new DRC error data file to attach to the current block. The name must be unique; the command fails if the specified name is already used by an error data file attached to the block.

drc_error_data

Specifies the collection that contains DRC error data object to attach. The collection must be derived from an external error data file, such as a previously exported error data file, a manually created error data file, or an error data file from a third-party tool.

`-keep`

Keeps the specified error data collection open and in memory.

By default, the command closes the specified error data collection.

Description

The *attach_drc_error_data* command attaches the specified error data file to the current block.

The command returns 1 if successful; 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example attaches the current physical DRC error data to a file that is named "dppinassgn.err".

```
prompt> attach_drc_error_data -name dppinassgn.err [get_drc_error_data]
1
```

- collections

---

attach_topology_nodes

Attaches topology nodes to objects valid for association with topology node

Syntax

collection *attach_topology_nodes*

```
[topology_node_list]
```

Data Types

```
topology_node_list  collection
```

Arguments

topology_node_list

Specifies the set of topology nodes for association with valid objects. If this is not specified then global selection set is used.

Description

The *attach_topology_nodes* command associates specified topology nodes with overlapped objects. Objects can be hierarchical. Allowed object types are pins, ports, cells, voltage_areas, voltage_area shapes, shapes, placement blockages, routing blockages, bounds, bound shapes, topology edges, bump regions, annotation shapes and terminals. Only overlapped objects can be chosen.

Pins and ports are having higher priority over cells in the case of many overlapping objects, and cells are having higher priority over all other types of objects. In addition, user can set the list of desired object types to be used for association by win_set_select_class command. When GUI is up and running the set of selectable object types is controlled by the View Settings panel.

Overlapped cell object can be replaced by its pins associated with topology plan nets if such pins are present and such replacement is not ambiguous.

If *topology_node_list* is specified, topology nodes from the list are used in the command. If it is not specified global selection is used.

The command returns collection of topology nodes for which attachment was established.

Feedback

Examples

The following example makes attempt to find proper objects for attachment for all topology nodes in the topology plan tp1.

```
prompt> attach_topology_nodes [get_topology_nodes -of_objects
 [get_topology_plans tp1]]
```

---

audit_scripts

Reads in a script, examines the application options and variables used in the script, and reports any changes to those application options or variables against a specified version of the tool.

The command also reports references to .tbc files.

Syntax

status *audit_scripts*

```
-input script_name_or_path
[-skip_hidden]
[-from version]
```

Data Types

```
script_name_or_path  string
version  string
```

Arguments

`-input` *script_name_or_path*

Specifies the location of the user scripts you want to audit. You can specify a single Tcl file or a directory name. If you specify a directory, the command audits all files in the directory with the .tcl suffix.

The tool issues an error message if *script_name_or_path* is not a valid file or directory.

`-from` *version*

A string specifying the tool version to compare your scripts against.

Note that only some tool versions are available for comparison, and that these versions can change across releases. To get a current list of the tool versions available for comparison, run the following command:

```
prompt> audit_script -input . -from x
Error: Value 'x' for option '-from' is not valid. Specify one of:
    18.06-sp5, 18.06-sp4, 18.06-sp2, 17.09-sp5 (CMD-031)
```

Feedback

By default, if the -from option is not specified, the command compares your script against the most current tool version available.

`-skip_hidden`

By default, the *audit_scripts* command reports hidden application options, variables, and Tcl commands. If you specify the -skip_hidden option, these items will not be reported.

Description

The *audit_scripts* command reads in one or more scripts, checks the scripts for any deprecated, removed, or otherwise changed application options and variables, and reports the results in an annotated version of each script. The annotated scripts are written to a subdirectory named ./audit, each with the same name as the original file.

An annotated script contains AUDIT_INFO and AUDIT_ERROR comments that provide information about each application option, application variable, and Tcl command change. These comments are also written to the command line output as information messages.

An annotated script might look like this:

```
# AUDIT_INFO at line 105: application option 'cts.verbose.buf' is
 unhidden.

# AUDIT_ERROR at line 147: application variable 'abor_enhance_inv_pair'
 is removed.

# AUDIT_ERROR at line 156: system-default of application option
'cts.use_global_route_atree_topology' is changed from true to atree.
```

AUDIT_INFO comments identify the following:

Application options/variables that have become hidden or unhidden

Application options that have been deprecated

Application options whose scope has changed (global v. block-scoped)

Application variables that can be replaced by application options

References to .tbc files

AUDIT_ERROR comments identify the following:

Application options/variables that have been removed

Application options/variables whose data type has changed

Application options/variables whose value, user-default value, or system-default value has changed (via an internal or user script)

Feedback

Note that the *audit_scripts* command evaluates application options and variables that have been specified with the following commands only:

```
set_app_options
reset_app_options
get_app_option_value
get_app_options
report_app_options
help_app_options

set
set_app_var
get_app_var
report_app_var
write_app_var
printvar
```

The *audit_scripts* command also evaluates commands that access application variables as Tcl variables:

```
set variable_name value
echo $variable_name
```

To repair any changed application options or variables in your scripts, you may either

Manually repair the application options/variables in your original scripts

Manually repair the application options/variables in the annotated scripts, and then copy the annotated scripts to the location of your original scripts

Examples

The following example audits the input script test.tcl and writes out an annotated test.tcl script to the ./audit directory:

```
prompt> audit_scripts -input test.tcl
```

This second example audits all the Tcl scripts in the scripts directory and writes out the annotated scripts to the ./audit directory:

```
prompt> audit_scripts -input scripts
```

Feedback

auto_partition_design

Partitions a design by regrouping logical hierarchies.

Syntax

```
collection auto_partition_design
[-from value]
[-to value]
[-check_only]
[-solution_to_select filename]
[-verbose]
```

Arguments

`-from value`

Specifies one of the values (generate_solutions | select_solution | apply_solution). On the basis of value, auto partition flow starts. generate_solutions: To perform the auto partitioning select_solution: To select the solution generated by above step. apply_solition: To commit the solution

`-to value`

Specifies one of the values (generate_solutions | select_solution | apply_solution). On the basis of value, auto partition flow ends generate_solutions: To perform the auto partitioning select_solution: To select the solution generated by above step. apply_solition: To commit the solution

`-check_only`

Performs sanity checks on the constraints set by set_auto_partition_constraints command.

`-solution_to_select filename`

Provides the filename as input to perform the selection of auto partition results.

`-verbose`

Shows detailed information.

Description

Partitions a design by regrouping logical hierarchies. Each partition is represented as a virtual group. You need to specify maximum cell count allowed in a partition or maximum number of partitions to be created using application options. You can specify the maximum pin count of a partition using application option. You can specify application option to make the partitioning physical aware.

Feedback

b

balance_clock_groups

Execute clock balance action among the clock balance groups.

Syntax

```
string balance_clock_groups
```

Description

This command will balance clocks insertion delay for all clock balance groups created by *create_clock_balance_group*.

See Also

- create_clock_balance_group
- report_clock_balance_groups
- remove_clock_balance_groups
- get_clock_balance_groups

c

capture_detailed_script_runtime

Enable detailed capture of runtime script report to a file.

Syntax

status *capture_detailed_script_runtime*

```
[-start]
[-stop]
[-output]
```

Feedback

Arguments

`-start`

Start detailed capture of report script runtime to a file

`-stop`

Stop detailed capture of report script runtime to a file

`-output`

Specify a file name for the output

Description

The *report_script_runtime* command reports the wall clock or CPU time used by commands issued on the current session. It also reports on the number of times the command was executed. The *capture_detailed_script_runtime* command enables detailed capture of runtime script report to a file.

See Also

- report_script_runtime

---

capture_qor_data

Captures custom QoR data into a QORsum panel.

Syntax

status *capture_qor_data*

```
-panel panel_name
[-label label_name]
[-output output_dir]
[-columns columns]
[-data data]
[-gui_setup tcl_code]
[-gui_cleanup tcl_code]
[-use_default_panel]
```

Data Types

```
panel_name              string
label_name              string
output_dir              string
columns                 list
data                    list
tcl_code                string
```

Feedback

Arguments

`-panel` *`panel_name`*

Specifies the name for the panel that is populated with data. This might be the name of a default *write_qor_data* summary table panel, or the name of a custom panel created with *define_qor_data_panel*. Default *write_qor_data* detailed table or image panels cannot be overwritten with this command.

`-label` *`label_name`*

Specifies a label for QoR data written to disk. The label is often referred to as the "stage" because a label typically represent the flow stage or step at which the data is written, such as *place_opt*, *post_cts*, or *compile_initial_opto*. The label is used in the file paths of the saved reports. The label is also used as the stage for the data in the QORsum web-based report generated by the *compare_qor_data* command. If a label is reused, the previously written data for that label for that panel name is overwritten.

The label must be specified, except when running the RTL Architect tool. When running the RTL Architect tool, the default label is *rtl_opt*, which matches the label used by the *explore_design* command.

Labels have strict naming restrictions to support various file system and URL naming rules. The valid characters are numbers (0-9), lowercase letters (a-z), uppercase letters (A-Z), dash (-), underscore (_), period (.), and plus (+).

`-output` *`output_dir`*

Specifies the path to a directory where all reports and QoR data tables are written to disk. By default, if a directory does not exist, the tool creates a directory at ./qor_data. If running the Fusion Platform Methodology (FPM) flow, the default output directory is ./rpts/qor_data, which is the same location used by the default QoR capture done in the FPM flow.

For a given run of a design through Synopsys tools, all data must be written to the same output directory. This ensures that a later call to the *compare_qor_data* command finds all labeled stages of a single run and shows them together as an ordered sequence of stages for that run. So, the same output directory name should be used for a given run for all calls to both *write_qor_data* and *capture_qor_data*.

`-columns` *`columns`*

Valid for summary and detailed panel types. Specifies the names of metrics or columns being captured in Tcl list format. The number of columns must match the number of fields on each line of data from the *-data* option.

Feedback

`-data` *data*

Valid for summary and detailed panel types. Specifies the data to be captured into the table for this panel. For summary table panels, *-data* is a Tcl list, with one data value corresponding to each column from the *-columns* option. For detailed table panels, *-data* is specified as a list of lists, where each of those lists represents a row of data captured into the table, again corresponding to the columns specified by *-columns*.

`-gui_setup` *tcl_code*

Valid for image panels. This opton specifies a block of Tcl code that is executed after the layout window is opened, before capturing the screenshot. This Tcl code should set up the layout view as you want for the image capture.

`-gui_cleanup` *tcl_code*

Valid for image panels. This opton specifies a block of Tcl code that is executed after the screenshot is captured. This block of code is option and can be used to cleanup any changes to the GUI view made for the image capture.

`-use_default_panel`

If there is a name conflict between a default *write_qor_data* panel and a custom panel defined by *define_qor_data_panel*, by default the custom user-panel is populated. Use this option to populate the default panel instead. Only default summary tables can be updated this way, not detailed tables or images.

Description

The *capture_qor_data* command is used to capture custom data into a panel defined by *define_qor_data_panel*. It can also be used to supplement a default *write_qor_data* summary table panel with additional metrics. It cannot be used to overwrite data in default *write_qor_data* detailed table or image panels.

Use the *-panel* option to specify the name of the panel for which QoR data is captured. This panel name must either be a custom panel created by *define_qor_data_panel*, or a default *write_qor_data* summary table panel.

While it is not recommended, it is possible to create a custom panel with *define_qor_data_panel* that has the same name as a default panel created by *write_qor_data*. In this case, the custom panel is populated with QoR data by default, unless the *-use_default_panel* option is used, in which case the *write_qor_data* panel is updated instead.

Like *write_qor_data*, the *-label* and *-output* options must be used to specify where the data is stored on disk. Data from *capture_qor_data* should be stored at the same location and with the same labels as used for *write_qor_data* for a given run. That way, all of the QoR data can be displayed in a single QORsum report created by the *compare_qor_data* command.

Feedback

For summary and detailed table panels, *-columns* must be specified, which gives a list of column or metric names that is captured in the panel. For summary panels, this list of metrics should not include the first *Stage* column shown in the QORsum report. That column is automatically derived from the labels of the captured data.

The *-data* option is used to specify the actual QoR data for summary and detailed table panels. For summary panels, *-data* takes a Tcl list of QoR metric values, corresponding to the metric names from the *-columns*. The length of the *-data* list must match the length of the *-columns* list. For detailed panels, *-data* takes a list-of-lists, where the outermost list captures each row of data for the detailed table, and the innermost lists are the contents of those rows, which again must correspond to the *-columns*.

For detailed table panels created with the *define_qor_data_panel -hierarchical* option, the first column contains hierarchical data that is displayed with a data-tree style view. Use the slash '/' character as a hierarchical separator in that first column's fields.

When populating a summary table, the update is made incrementally. This means you can add new metric data to an existing summary table panel that already contains data. You can also incrementally overwrite the values of metrics that were previously populated. A typical application of this behavior is to add new metrics to default *write_qor_data* summary panels.

Detailed table data cannot be updated incrementally. If data was previously captured by *capture_qor_data* for that table and then it is captured again for the same label and output directory, then the old data is overwritten by the new.

For image panels, instead use the *-gui_setup* option to specify how the image is captured. Image capture is supported for the GUI layout window in IC Compiler II, Fusion Compiler, and RTL Architect. The *capture_qor_data* command handles the details of opening the GUI, opening a layout window, taking the screenshot, and then closing the layout window and GUI. *-gui_setup* specifies a block of Tcl code to execute after the layout window is opened, but before the screenshot is captured. It is used to configure the GUI display to capture exactly the image you want. While is it possible to set up some aspects of the GUI display prior to calling *capture_qor_data*, such as selection, highlighting, and visual mode options, since these are global settings. But many GUI commands are tied to a specific layout window and must be specified in this script. For simplicity, it's recommended to put all of the GUI layout view setup in this script.

The *-gui_cleanup* option also takes a block of Tcl code as the argument, and can optionally be used to cleanup some of the GUI view changes you made. It is be executed after the screenshot is captured and before the layout window is closed.

For both of the *-gui_setup* and *-gui_cleanup* scripts, do not try to manage anything related to opening or closing the GUI or layout window. Also do not manually capture the screenshot in those scripts, or resize the GUI layout window. All of that is handled automatically. Use the scripts only to setup or cleanup the view of an existing layout

Feedback

window. The variable $window is available as a local variable in these two blocks of Tcl code for referring to the layout window opened by *capture_qor_data*.

Examples

```
## Define a summary table and capture data incrementally
prompt> define_qor_data_panel -name "My Summary" -type summary
prompt> capture_qor_data -panel "My Summary" -label place_opt
           -columns "WNS" -data "-0.123"
prompt> capture_qor_data -panel "My Summary" -label place_opt
           -columns "TNS NVE" -data "-12.2 534"

## Define and capture a detailed table with three rows and three columns
prompt> define_qor_data_panel -name "My Detailed Table" -type detailed
prompt> capture_qor_data -label place_opt -columns {Layer VRWirelen
 DRWirelen}
           -data { {M4 23020 23126} {M5 28855 28823} {M6 13438 13566} }

## Define and capture an image
prompt> define_qor_data_panel -name "My Image" -type image
prompt> capture_qor_data -panel "My Image" -label place_opt
           -gui_setup { gui_change_highlight -collection [get_cells
 *ZBUF*] -color yellow }
           -gui_cleanup { gui_change_highlight -remove -all }
```

- set_qor_data_options
- capture_qor_data
- set_qor_data_metric_properties

---

change_abstract

Changes the view of the cells.

Syntax

status *change_abstract*

```
[-view design | abstract]
[-label label_name]
[-lib library]
[-reload]
```

Feedback

```
[-force]
[-update_ref_libs]
-references reference_list
-cells cell_list
```

Data Types

```
label_name      string
library         string
reference_list  list
cell_list       collection
```

Arguments

`-view design | abstract`

Change the listed references or cells to the given view type. If the *-view* option is not given, then the new referenced block will have the same view type as the original block.

Valid arguments for *-view* are *design* and *abstract*.

`-label label_name`

Change the listed references to the block with the given label. To change to the default label, specify an empty *label_name* as *change_abstract -label ""*.

If the *-label* option is not given, the new referenced block will have the same label as the original block.

`-lib library`

Change the listed references to the block in the given library. The given library must be already opened. If the *-lib* option is not given, the new referenced block will be opened from the same library as the original block.

To change to a new block from a given library, that library must first be listed in the "ref-lib list" of the designs that contain it unless the *-update_ref_libs* option is specified. Use the *set_ref_libs* command to add the library to the ref-lib list.

`-reload`

Reload the blocks of the listed references from disk. The in-memory copy of the block will be discarded. This option cannot be used in combination with *-view*, *-label*, or *-lib*. The reference will point to the original block after the command is executed.

The *-reload* option is useful if you want to load a block that has recently been updated by some other processing. For example, the block may have been optimized on a distributed server.

Specifying the *-reload* option automatically turns on the *-force* option.

Feedback

`-force`

Change the block reference, even if the ports of the new referenced block do not match the original block. By default, the *change_abstract* command issues an error message and exits.

When the new block has different ports, there is a chance that your design will be compromised. For example, if the new block is missing ports, it may be necessary to drop connections and/or constraints.

`-update_ref_libs`

Add the block library to the ref-lib list of the designs that contain it if it is not already in the ref-lib list. If an existing library in the ref-lib list has the same name as the block library, it is replaced with the block library.

`-references` *`reference_list`*

Specifies a list of names of referenced blocks. All cells that point to the referenced block will be changed as specified by the *-view*, *-label*, *-lib*, and *-reload* options. The list must not contain patterns or collections, only simple block names.

`-cells` *`cell_list`*

Specifies one or more physical hierarchy cells to change. You must specify the *-view* option together with the *-cells* option. The *-cells* option must not be used with *-label* or *-lib*.

Description

This command changes the current bound block of the given cells. The operation of the *change_abstract* command is similar to the *change_view* and *set_reference* commands, except that hierarchical design constraints that cross block boundaries are preserved. The *change_view* and *set_reference* commands discard all constraints that are inside or cross the boundary of the changed references.

The *change_abstract* command works only with "design" and "abstract" views. These two views are guaranteed to have equivalent function and equivalent port interfaces. This makes it possible to preserve constraints. If you are trying to change to or from other views, or if your port interface is different, you should use the *set_reference* command instead.

Alternative to change_abstract

The *change_view* and *set_reference* commands discard all constraints that are inside or cross the boundary of the changed references. If you use commands other than *change_abstract* you will need to reapply constraints to your design when you are done. You can do this by rereading constraints from your original SDC file.

Feedback

Examples

The following example replaces the references to blocks blockA and blockB to the place_opt label of the blocks.

```
prompt> change_abstract -label place_opt -references {blockA blockB}
```

The following example replaces the design view of the given subblocks with an abstract view. Constraint that were originally applied to the subblock from the top level are preserved. The constraints that were saved with the abstract subblock are not promoted to the top level.

```
prompt> change_abstract -view abstract -cells {i_mmu i_fpu1}
```

The following example replaces all cell instances of "FPU" with an abstract view.

```
prompt> change_abstract -view abstract -references FPU
```

The following example uses the *-update_ref_libs* option to replace the reference to block "blockC" located in reference library "oldPath/refLibC" to the one located in the library "newPath/refLibC" and update the reference library list to contain "newPath/refLibC" instead of "oldPath/refLibC".

```
prompt> open_lib newPath/refLibC
prompt> change_abstract -lib newPath/refLibC -references blockC
        -update_ref_libs
```

- remove_modes
- remove_corners

---

change_link

Changes the design to which a cell is linked.

Syntax

status *change_link*

```
[-design design]
cells
design_name
```

Feedback

Data Types

```
cells     list
design_name     string
```

Arguments

`-design design`

Specifies the design from which to change the link for the given cell(s). If no design is specified, the current design is used.

cells

Specifies the cells in the current design for which the link is to be changed.

design_name

Specifies the name of the design to which the cells in *cells* are to be linked.

Description

The *change_link* command specifies a design for which the link for a cell is to be changed. Hence a cell is changed to be one occurrence of the specified design.

The cell can only be changed to a compatible design. For example, the design must have the same number of ports with the same name and direction as the cell.

Although the *design_name* argument accepts names in the format *library/library_cell*, it does not imply that the actual library cell used for the new cell will be from the specified library. The actual library cell used is determined by the current link library settings.

During *change_link* activity, all Synopsys database format link information is copied from the old design to the new design. If the old design is a synthetic module, all attributes of the old synthetic module are moved to the new link. After running the *change_link* command, link the design with the *link_block* command.

Examples

The following example shows the use of *change_link* to change the reference of the U1 cell to BUFX3 from INVX3:

```
prompt> get_attribute [get_cells U1] ref_name
INVX3
1

prompt> change_link [get_cells U1] BUFX3
1

prompt> get_attribute [get_cells U1] ref_name
BUFX3
1
```

Feedback

See Also

- link_block
- set_reference

---

change_names

Changes the names of ports, cells, and nets in a design by applying a set of rules previously defined by the *define_name_rules* command, or renames a specified instance.

Syntax

status *change_names*

```
[-rules rule_name]
[-hierarchy]
[-names_file names_file]
[-restore]
[-force]
[-include_sub_blocks]
[-log_changes log_file]
[-dont_touch object_list]
[-instance instance]
[-new_name new_name]
[-verbose]
[-nosplit]
[-skip_physical_only_cells]
```

Data Types

```
rule_name       string
names_file      string
log_file        string
object_list     collection
instance        collection
new_name        string
```

Arguments

`-rules rule_name`

Specifies the name of a rule set previously defined by the *define_name_rules* command, or the predefined *verilog* rule set. The command changes the names of objects in the design according to the specified rule set.

`-hierarchy`

Changes objects in the full hierarchy of the design and does not cross over into other physical hierarchies or sub blocks. By default, only the objects of top logical hierarchy are changed.

Feedback

`-names_file` *`names_file`*

Specifies a file of manual name changes. These name changes are not subject to any name rules, but a warning is reported if any name changes are not unique. By default, the command automatically makes name changes based on the names mentioned in the names file. If you specify this option, the tool ignores the *-rules* option.

`-restore`

Reverses the changes recorded in the *names_file* during the current session and restores the contents of the file to the state it was in when opened.

`-force`

Force option along with *names_file* option, changes the names of regular bus members, even the names file entries makes it irregular. After it becomes irregular, it is bitblasted. Without force option if the result of change_names with names_file makes a bus from regular to irregular, those changes are not applied.

`-include_sub_blocks`

By default, objects of top logical hierarchy are considered. When *-hierarchy* option is used then all objects within current physical hierarchy is considered and it doesn't cross over into other physical hierarchies or sub blocks. With this option specified, it crosses over into other physical hierarchies also and in doing so it considers only the bound views. If an instance in top level is bound to non design view of a sub block like for example, abstract, then the command errors out. This is because design view can't be derived from a non design view and changing non design view causes it to go out of synchronisation with its design view. In order to consistently rename all the design data and associated timing constraints, only design views should be used for linking. This option can't be used independently and has to be used along with *-hierarchy*. If any of the sub blocks is not yet linked then using this option first links those sub blocks and then change the names. Include_sub_blocks option is not supported along with *-names_file* option.

`-log_changes` *`log_file`*

Specifies a log file in which to record the name changes. By default, no log file is written.

`-dont_touch` *`object_list`*

Specifies a list of objects that are not to be changed. If an object is included in dont_touch, change_names won't be operational on that object.

Changes applied on this object is applied on reference module of that object so, the changes are applied on all instances of reference module For Example- If a

Feedback

module M is instantiated as U1 and U2 and you give -dont_touch as U1/A then both U1/A and U2/A is not modified.

`-instance` *`instance`*

Changes the name of an instance in the design. This option can be used only with the *-new_name* option, and not with other options. The command changes the instance name to the specified new name.

`-new_name` *`new_name`*

Specifies the new instance name when the *-instance* option is used. The new name might contain only alphanumeric characters and the underscore character (_) and must start with a letter. New name specified must not be the full hierarchical name, instead it should only be the leaf level name. The new name cannot be a reserved word used by Verilog, SystemVerilog, or VHDL, and must not conflict with an existing instance, port, and net name within the same design. Any leading backslash character is removed.

`-verbose`

Reports every name change. By default, the tool reports only a summary showing the number of name changes for each object type.

`-nosplit`

Most of the verbose information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The *-nosplit* option prevents line-splitting. This option cannot be specified without *-verbose* option.

`-skip_physical_only_cells`

Specifies that, physical only type of cells should not be considered for name changes. This is applicable for nets and ports of these type of cells as well.

Description

The *change_names* command changes the names of ports, cells, and nets in the current design as needed to conform to specified naming rules. By applying an appropriate set of naming rules, you can write out design data files that are compatible with the requirements of the target external tool when you use the *write_verilog*, *write_def*, or *write_gds* command.

To define a set of naming rules to be used with the *change_names* command, use the *define_name_rules* command. Alternatively, you can use the predefined *verilog* rule set.

To report the available sets of rules, including the predefined *verilog* rule set, use the *report_name_rules* command.

Feedback

To preview the changes to the design that would be made by applying the *change_names* command, but without actually preforming those changes, use the *report_names* command.

To change the name of a specific instance in the design, use the *change_names* command with the *-instance* and *-new_name* options. These options cannot be used together with the other command options.

The *change_names* command can change the names of objects in design libraries only, not the names of leaf-level cells in reference libraries. To modify reference libraries, use the Library Manager tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Names File Format

To specify a name change, you must specify the following four fields:

design_name object_type object_name new_name

The *design_name* field is a design currently read into the tool.

The *object_type* field is *port*, *cell*, or *net*.

The *object_name* field is the name of an object within the specified design.

The *new_name* field is the name that replaces the existing name.

If the file contains a report bar formed by min 10 dashed line (--------), the tool ignores all information above the report bar.

The tool parses all lines after the report bar (or all lines, if the file does not contain a report bar).

By default, the tool parses each line into four fields, which are separated by whitespace characters, such as blanks, tabs, or new lines.

This format matches the format of the *report_names* command output, which allows you to redirect the output of the *report_names* command to a file, edit it, and then use it as input to the *change_names* command.

The following example shows a names file format.

Design Type Object New Name

TOP cell U$1 U_1

TOP net NET_NAME_IS_WAY_TOO_LONG NET_NAME_IS_WAY_TOO

Feedback

TOP net 12345 N12345

```
prompt> change_names -names_file name.change -verbose
```

Examples

The following commands change the names of ports, nets, and cells in the top logical hierarchy of the current design by converting all lowercase "a" characters to uppercase "A".

```
prompt> define_name_rules my_map_rule -map {{"a","A"}}
1
prompt> change_names -rules my_map_rule
 Information: Using name rules 'my_map_rule'.
 Information: 908 objects (124 ports, 144 cells, ... ) changed in design
 'core1'.
1
```

The following command changes the name of instance u0_0 to u0_AB. (This command does not use any naming rules.)

```
prompt> change_names -instance u0_0 -new_name u0_AB
1
```

The following command changes the name of instance old_inst_name in hierarchy A/D to new_inst_name. (This command does not use any naming rules.)

```
prompt> change_names -instance A/D/old_inst_name -new_name new_inst_name
1
```

The following command changes the names in the design to meet Verilog naming conventions using the predefined *verilog* rule set. Using the *define_name_rules* command is not needed.

```
prompt> change_names -rules verilog
 Information: Using name rules 'verilog'.
 information: 601 objects (123 ports, ... ) changed in design 'topAC'.
1
```

Note: The predefined *verilog* rule set used in this example is somewhat different from using the *-special verilog* option in the *define_name_rules* command. The *-special verilog* option in the *define_name_rules* command implicitly invokes the following rules:

```
-collapse_name_space
 -equal_ports_nets
 -inout_ports_equal_nets
 -remove_irregular_port_bus
 -remove_irregular_net_bus
```

Feedback

Using *change_names -rules verilog* invokes these same rules, but also invokes the following additional rules:

```
-check_internal_net_name
 -check_bus_indexing
 -flatten_multi_dimension_buses
 Do not use reserved words (long list)
 Use only alphanumeric characters
 Start names with a letter
```

Using the *-special verilog* option in the *define_name_rules* command is more flexible because you can add more rules to your custom rule set. The *change_names -rules verilog* command cannot be customized.

For details of the exact rules invoked by the *verilog* keyword, use the *report_name_rules* command.

---

change_pin_arrangement

Change pin arrangement.

Syntax

string *change_pin_arrangement*

```
[-pins pins]
[-nets nets]
[-layers layers]
[-style interleaving | stacking | reduce_crossing]
[-ignore_short]
```

Data Types

```
pins                collection
nets                collection
layers              collection
```

Arguments

`-pins pins`

Limits the pin arrangement change to the specified collection of pins.

Feedback

`-nets` *net_collection*

Limits the pin arrangement change to the specified collection of nets.

`-layers` *layers*

Specifies the tech layers for pins to change pin arrangement. This option is applicable only to interleave or stack pins. If *-layers* is specified, only the specified layers are used for pins in sequence.

`-style interleaving | stacking | reduce_crossing`

Specify changing style.

`-ignore_short`

In some cases, pin arrangement won't be changed because change pin arrangement may cause short violations. If this option specified, pin arrangment can be changed even if it causes short violations.

Description

This command performs the pin arrangement change on specified pins or nets The change is limited to two-pin nets. Ihis command may ignore the possible issues caused by the change, such as overlap, tech size violation, short pin issue.

Examples

The following example stacks specified pins. After it, A1/out1, A1/out2 and A1/out3 are stacked on the same location, and with layers METAL1, METAL3, METAL5 respectively; A1/out4, and A1/out5 are stacked on the same location, and with layers METAL1, METAL3 respectively.

```
prompt> change_pin_arrangement -pins {A1/out1 A1/out2 A1/out3 A1/out4
 A1/out5} -layers {METAL1 METAL3 METAL5} -style stacking
```

The following example interleaves specified pins. After it, B1/out1, B1/out2 and B1/out3 are interleaved on neighoring locations, and with layers METAL1, METAL3, METAL3 respectively.

```
prompt> change_pin_arrangement -pins {B1/out1 B1/out2 B1/out3} -layers
 {METAL1 METAL3} -style stacking
```

---

change_reference

Rebinds hierarchical cells to a new reference cell

This command is deprecated, please use set_reference command.

Syntax

collection *change_reference*

Feedback

```
[-design reference_design]
[-module module_name]
[-verbose]
cell_list
```

Data Types

```
reference_design  design name or collection
module_name       string
cell_list         list
```

Arguments

cell_list

Specifies the list of hierarchical cells to be rebound to new reference. Each cell must be in scope (at or below the current instance).

-design *reference_design*

Specifies the new design to which the specified cells are to be bound. The specified cells must be currently bound to another design. The argument can be a design name or a collection of one design. The cells must be bound to a design with the same port interface as the new design. This argument is mutually exclusive with *-module*.

-module *module_name*

Specifies the name of an existing module in the current design to which the specified cells are to be bound. The specified cells must be currently bound to another module. The new module must have the same port interface as the module the cells are currently bound to. This argument is mutually exclusive with *-design*

-verbose

Prints additional information.

Description

The *change_reference* command changes the reference of the given list of hierarchical cells. All the specified cells must have the same current reference. The new reference and the current reference of the cells must have the same exact port interface. This means that the number of ports, port directions and port names must be the same. Further, the current and new references must be of the same *type*. This means that if the current reference of the cell is a design, the new one must also be a design and if the current reference is a logical module in the current design, the new one also must be a logical module in the current design. The new reference must already exist. Further, when the reference is a design, the reference design with the view bound currently, must exist. The view bound to the cell is not changed.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

In the following examples, change_reference is used for changing the reference of cells bound to designs and logical modules

```
prompt> change_reference -design [get_designs alu_1] u1
1

prompt> change_reference -module logical_alu {u2 u3}
2
```

---

change_selection

Changes the selection in the GUI, taking a collection of objects and changing the selection according to the type of change specified.

Syntax

int *change_selection*

```
[-name slct_bus]
[-replace]
[-add]
[-remove]
[-toggle]
[-push]
[-undo]
[-type object_type]
collection
```

Data Types

slct_bus	string
object_type	list
collection	list

Feedback

Arguments

`-name` *`slct_bus`*

Specifies to change the selection bus by using the value of *slct_bus*. By default, the command changes the selection bus by using the name *global*.

`-replace`

Replaces the current selection with the objects in the collection. This is the default behavior of the command if you do not specify any optional parameter.

`-add`

Adds the objects in the collection to the current selection. By default, this option is off.

`-remove`

Removes the objects that are specified in the collection from the current selection. By default, this option is off.

`-toggle`

Adds each item that is specified in the collection to the selection bus if it is not currently contained there. If it is currently contained in the selection bus, remove it. By default, this option is off.

`-push`

Pushes current selection onto selection stack before changing the selection.

`-undo`

Undo to previous selection.

Undo is single level so running undo twice will return to original selection.

`-type` *`object_type`*

Specifies the type to change. Only those items from the collection that are of the type specified by *object_type* are used to change the selection. The valid values are *design*, *port*, *net*, *cell*, *pin*, and *path* (timing path). By default, the command uses the entire collection.

`collection`

Specifies the collection of objects to use to change the selection. The type of change that is applied to the current selection with the *collection* is specified by the optional parameters listed above. By default, this option is off.

Description

The *change_selection* command changes the selection in the GUI. When selections are changed, the GUI updates all relevant windows to reflect it.

Feedback

A collection of objects and the type of change are given as input to the command. The collection of objects might be returned as the result of another command such as the *get_designs* command. If the collection is empty and you use the *-replace* option (or let the command default by specifying no option), the current selection is cleared.

If you use the *-type* option, only the type of objects specified are used to change the current selection. For example, if you use *-type design*, the command uses only the design objects in the collection to change the current selection. If you do not use *-type* option, all objects in the collection are used to change the current selection. For example, if you use the *-add* option without using the *-type* option, all objects, regardless of their type, are added to the current selection.

For information about collections, see the *collections* man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example replaces the current selection with the collection of design objects, regardless of type.

```
prompt> change_selection [get_designs]
```

The following example adds a cell named U5 to the selection made in the example above.

```
prompt> change_selection -add [get_cells U5]
```

The following example removes all pin objects from the current selection.

```
prompt> change_selection -remove -type pin [get_selection]
```

The following example clears the selection.

```
prompt> change_selection ""
```

The following example creates a new selection bus and adds a net named n1 to the selection.

```
prompt> set slct [create_selection_bus]
prompt> change_selection  -name $slct [get_nets 1]
```

See Also

---

change_view

Changes the view of the cells.

NAME

change_view

Changes the view of the cells.

Syntax

status *change_view*

```
[-view view_type]
[-label label_name]
[-lib library]
[-reload]
[-force]
[-update_ref_libs]
-references reference_list
-cells cell_list
```

Data Types

```
view_type       string
label_name      string
library         string
reference_list  list
cell_list       collection
```

Arguments

`-view view_type`

Specifies the name of view type to use.

If you do not specify the *-view* option, the command resets the reference view of the specified cells to the original view set by the linker and the view switch list.

Valid values for the *view_type* argument are *abstract*, *conn*, *design*, *error*, *frame*, *layout*, *outline*, and *timing*.

`-label label_name`

Change the listed references to the block with the given label. To change to the default label, specify an empty *label_name* as *change_abstract -label ""*.

Feedback

If the *-label* option is not given, the new referenced block will have the same label as the original block.

`-lib` *`library`*

Change the listed references to the block in the given library. The given library must be already opened. If the *-lib* option is not given, the new referenced block will be opened from the same library as the original block.

To change to a new block from a given library, that library must first be listed in the "ref_lib list" of the designs that contains it. unless the *-update_ref_libs* option is specified. Use the *set_ref_libs* command to add the library to the ref_lib list.

`-reload`

Reload the blocks of the listed references from disk and discard the in-memory copy of the block. This option cannot be used in combination with *-view*, *-label*, or *-lib*. The reference will point to the original block after the command is executed.

The *-reload* option is useful if you want to load a block that has recently been updated by some other processing. For example, the block may have been optimized on a distributed server.

Specifying the *-reload* option automatically enables the *-force* option.

`-force`

Change the block reference, even if the ports of the new referenced block do not match the original block. By default, the *change_abstract* command issues an error message and exits.

When the new block has different ports, there is a chance that your design will be compromised. For example, if the new block is missing ports, it may be necessary to drop connections and/or constraints.

`-update_ref_libs`

Add the block library to the ref-lib list of the designs that contain it if it is not already in the ref-lib list. If an existing library in the ref-lib list has the same name as the block library, it is replaced with the block library.

`-references` *`reference_list`*

Specifies a list of names of referenced blocks. All cells that point to the referenced block will be changed as specified by the *-view*, *-label*, *-lib*, and *-reload* options. The list must not contain patterns or collections, only simple block names.

Feedback

`-cells` *`cell_list`*

Specifies one or more physical hierarchy cells to change. You must specify the *-view* option together with the *-cells* option. The *-cells* option must not be used with *-label* or *-lib*.

Description

This command changes the current bound view for one or more cell instances.

If the specified view type does not exist for one or more of the cell instances, the command returns an error status and does not change the bound view for those cells. However, the command does change the bound view for the other cells.

The bound view for cells in the top block is persistent. The bound view for cells in child blocks is not persistent. After a block hierarchy is saved and restored, the bound views in the top block are preserved and the bound views for cells within child blocks revert to the binding saved for that cell within that child block.

CAUTION

The *change_view* command is not intended for use on designs that have top-down constraints applied. If you use the *change_view* command, constraints that apply to the block or span the block boundary are lost and you must reapply your constraints from an SDC file. If your design has top-down constraints, you should use the *change_abstract* command.

Once all the invocations of *change_view* are done, a follow up call to the command *link_block -force* is to be done in some cases. This should be done when the block to which the cell is to be changed is either of *module* or *blackbox* design type.

Examples

The following example replaces the existing design view with the outline view for the cell instance named u1/mem1:

```
prompt> change_view -view outline u1/mem1
```

The following example specifies that the design view is to be used for the cell instance named u1/mem1:

```
prompt> change_view -view design u1/mem1
```

The following example specifies that the view switch list should be used to determine the bound view for the cell instance named u1/mem1:

```
prompt> change_view u1/mem1
```

Feedback

The following example specifies that the abstract view is to be used for all cells that reference the block named MIDDLE:

```
prompt> change_view -view abstract -references MIDDLE
```

The following example uses the *-update_ref_libs* option to replace the reference to block "blockA" located in reference library "oldPath/refLibA" to the one located in the library "newPath/refLibA" and update the reference library list to contain "newPath/refLibA" instead of "oldPath/refLibA".

```
prompt> open_lib newPath/refLibA
prompt> change_view -lib newPath/refLibA -references blockA
        -update_ref_libs
```

---

characterize_block_pg

Writes out power and ground creation constraints, including via master rule, pattern, strategy, and strategy via rules, for each block in preparation for distributed PG creation. The constraints are based on the top-level power ground creation constraints in the hierarchical design. The command creates a power ground constraint script for each block with the same reference design. The script can be used to regenerate power and ground at the block level. The scripts are created under the pgroute_output directory in the current path. The command writes out a mapping file when you use the *-compile_pg_script* option. The map file specifies the PG constraints and script to use with the *compile_pg* command during distributed PG creation.

Syntax

status *characterize_block_pg*

```
[-output_directory directory_name]
[-compile_pg_script file_name]
```

Feedback

Data Types

```
directory_name    string
file_name         string
```

Arguments

`-output_directory` *directory_name*

Specifies the output directory name for the generated block-level PG script files. The directory is created under the current path. If not specified, "pgroute_output" is used as the output directory.

`-compile_pg_script` *file_name*

Specifies the *compile_pg* script file name. The script can contain PG route application options and *compile_pg* commands, but should not include PG via master rule, pattern, strategies and strategy via rule commands.

When this option is specified, the command writes out a PG mapping file called "pg_mapfile" into the output directory specified by the *-output_directory* option. This mapping file specifies the PG constraint and PG *compile_pg* script for each block, and is needed for distributed PG creation. The PG constraint for the current top-level design is not included inside the mapping file since the top-level PG constraint has already been defined and is persistent.

By default, the mapping file is not generated. A sample map file is as follows:

```
leon3s    PG_CONSTRAINT  ./leon3s_pg.tcl
leon3s_2  PG_CONSTRAINT  ./leon3s_2_pg.tcl
leon3s_3  PG_CONSTRAINT  ./leon3s_3_pg.tcl

leon3s    COMPILE_PG     ./compile_pg_script.tcl
leon3s_2  COMPILE_PG     ./compile_pg_script.tcl
leon3s_3  COMPILE_PG     ./compile_pg_script.tcl
leon3mp   COMPILE_PG     ./compile_pg_script.tcl
```

Description

This command characterizes PG creation constraints, including via master rule, pattern, strategy, and strategy via rule for each block based on the top-level constraints in the hierarchical design.

This command writes out a map file that contains a list of PG constraint files and block names for each block. Before proceeding with distributed PG creation with the *run_block_compile_pg* command, the mapping file name must be assigned with the *set_constraint_mapping_file* command.

Examples

The following example characterizes PG creation constraints for all-level of physical hierarchy in the hierarchical design.

Feedback

```
prompt> characterize_block_pg -compile_pg_script pg_script.tcl
```

The following example characterizes PG creation constraints for up-to second level of physical hierarchy in the hierarchical design.

```
prompt> set_editability -value false -from_level 3
prompt> characterize_block_pg -compile_pg_script pg_script.tcl
```

---

characterize_memory

Characterizes memory lib_cells to collect information such as NW, NB, address/data/clock/enable pins, area, power, delay etc.

Syntax

characterize_memory

```
[-lib_cells memory_lib_cell_list]
[-transition value]
[-capacitance value]
[-export path]
[-import path]
```

Feedback

```
[-force]
[-reset]
[-clock_pin_name string_list]
[-enable_pin_name string_list]
[-address_pin_name string_list]
[-data_in_pin_name string_list]
[-data_out_pin_name string_list]
[-reference_db string_list]
[-reference_lef string_list]
```

Data Types

memory_lib_cell_list	list or collection
value	float
path	filename string
string_list	name list

Arguments

`-lib_cells` *memory_lib_cell_list*

Specifies the library cell of the memory to be characterized. If not specified, all memory library cells in the reference libraries are identified using the is_memory_cell attribute.

`-transition` *value*

Specifies the transition time to be used for timing and power calculation. If not specified, the nominal transition of the design is used.

`-capacitance` *value*

Specifies the pin capacitance to be used for timing and power calculation. If not specified, the nominal capacitance of the design is used.

`-export` *path*

Specifies the CSV file path and file name to which the memory information is saved. If not specified, only the memory information is printed in the log.

`-import` *path*

Specifies the memory information CSV file path and file name to be read in instead of the tool characterization.

`-force`

If specified, the tool re-characterizes the memory and overwrites the in-memory data

`-reset`

If specified, the tool clears all characterized in-memory data.

Feedback

`-clock_pin_name` *`string_list`*

Specifies the clock pin name on the memory library cell. If not specified, the pin with the clock==true attribute is identified.

`-enable_pin_name` *`string_list`*]

Specifies the enable pin name on the memory library cell. If not specified, enable pins are not identified.

`-address_pin_name` *`string_list`*

Specifies the address bus pin name on the memory library cell. If not specified, the address pin is derived from NW

`-data_in_pin_name` *`string_list`*

Specifies the data input bus pin name on the memory library cell. If not specified, the data input pin is derived from NB.

`-data_out_pin_name` *`string_list`*

Specifies the data output bus pin name on the memory library cell. If not specified, the output bus pin is treated as the data output pin.

`-reference_db` *`string_list`*

Specifies the db files for the memory cells, and a fusion library is created from these files.

`-reference_lef` *`string_list`*

Specifies the lef files for the memory cells, and a fusion library is created from these files.

Description

The *characterize_memory* command collects information from memory library cells and prints the information in a log file or exports it to a CSV file. You can review this information, update it, and import it back. Such information is used by the *filter_memory* command to statically select memory library cells for memory wrappers in a design.

The collected information is in a table with following head row:

```
lib
 cell,NW,NB,type,address1,address2,data_in1,data_in2,data_out1,data_out2,
clock1,clock2,enable1,enable2,area,height,width,corner,nominal
 slew,nominal capacitance,leakage power,internal power,read delay,write
 delay
```

Feedback

Examples

The following example characterizes all memory lib cell and exports result in mem_charz.csv file:

```
prompt> characterize_memory -export mem_charz.csv
```

The following example imports memory characterization information from import_mem_charz.csv file:

```
prompt> characterize_memory -import import_mem_charz.csv
```

---

characterize_topology_plans

Pushes down topology plans, nodes, edges, and repeaters into blocks within the hierarchy as needed.

Syntax

string *characterize_topology_plans*

```
[topology_plan_list]
```

Data Types

```
topology_plan_list  collection
```

Arguments

topology_plan_list

Specifies a list of topology plans to characterize. The list can contain topology plan names, patterns, or collections. A collection can be specified by using the *get_topology_plans* command.

Description

The *characterize_topology_plans* command pushes down topology plans, nodes, edges, and repeaters into blocks within the hierarchy. If *topology_plan_list* is specified, those topology plans are characterized. If it is not specified, then all topology plans in the current block are characterized.

Examples

The following example pushes down topology plans, nodes, edges, and repeaters into blocks for the current topology plan.

```
prompt> characterize_topology_plans [current_topology_plan]
```

Feedback

See Also

- optimize_topology_plans
- propagate_topology_plans

---

check_3d_design

Checks a 3DIC design for physical and electrical connectivity. The command checks connectivity and chip design information inside the 3DIC design and between two neighboring stacked chips.

Syntax

status *check_3d_design*

```
[-chip_placement]
[-physical_contact]
[-logical_physical_consistency]
[-connectivity]
[-matching_type]
[-bump_cluster]
[-physical_design_rule]
[-power]
[-dies die_list]
[-die_pairs die_pair_list]
[-exclude_dies die_list]
[-no_probe_pad]
[-verbose]
[-error_view]
[-tech_files]
[-group_by_id]
[-feedthrough]
[-exclude category_list]
[-flyline_analysis]
```

Data Types

```
die_list                list
die_pair_list  list
```

Arguments

`-chip_placement`

Checks the vertical level and overlap of the top-level chip. If two chips are specified with the same z (vertical level) value, they should not overlap. If two chips are neighboring, the chip with the larger virtual top-level area should contain the other one.

Feedback

`-physical_contact`

Checks the correctness of physical contacted bumps. Inter-chip physical contact information includes the following:

- Non-aligned bump pairs
- Bumps that do not physically connect to a bump on the adjacent side of a vertical neighboring chip
- Bumps that contact more than one bump of a neighboring chip
- Overlap of a bump and another bump in a single chip

`-logical_physical_consistency`

Checks the logical and physical consistency of the design. If the top-level port instance pair does not have a corresponding physical bump pair, the command issues an error message.

`-connectivity`

check connectivity of the design.

`-matching_type`

Checks the matching type mismatch on logical connection and physical contact among all dies in the 3D design.

`-bump_cluster`

Checks the bump cluster in design for the following conditions:

- Bump cluster in a chip should has no more than 1 nets;
- If one bump in the physical contact pair belongs to a cluster, the other bump in the physical contact pair should also belong to another cluster.

`-physical_design_rule`

Checks the following constraints:

- TSV to TSV spacing constraint, which use the "minCutSpacing" defined in the tech file
- TSV to cell boundary spacing constraint, which use the "tsvKeepoutSpacing" defined in the tech file

`-power`

Checks power/ground net continuity.

Feedback

`-dies`

Only show violations on specified dies. If the specified die is hierarchy die, the command will check all leaf dies in the hierarchy die.

`-die_pairs`

Only show violations between specified die pairs. If the die in the specified die pairs is hierarchy die, the command will check all leaf die pairs in the hierarchy die.

`-exclude_dies`

Filter these violations on specified dies. If the specified die is hierarchy die, the command will filter all leaf dies in the hierarchy die.

`-no_probe_pad`

Don’t display violations involving probe pads.

`-verbose`

Prints detailed information. If you omit this option, the command prints only part of messages and a summary of the information.

`-error_view`

Specify the file name that would be used for GUI error browser. The default file name is "check3dDesign.err".

`-tech_files`

Check the if the tech files in the design have difference. The command detects when multiple tech files are used inside a single die, as this is invalid.

`-group_by_id`

Report the messages by message ID.

`-feedthrough`

Check if all chips in the design need to punch new ports during the process of assign/propagate top nets.

```
-exclude [chip_placement | physical_contact |
logical_physical_consistency | matching_type | bump_cluster |
physical_design_rule | connectivity | pg | tech_files | feedthrough]
```

Specify which category will not be checked, this option should not be specified with the command category options.

`-flyline_analysis [all|signal|pg]`

Create a report of net_based flyline analysis showing total length, crossings, flyline source point that are dangling or outside of its sink bounding box. Flyine

Feedback

are created based on bumps and TSVs of the nets. Signal net flylines represent its signal flow direction and PG net flylines represent the power delivery flow in a 3DIC stack. The Error Browser can be used to examine details such as flyline crossings, with cross probing from the GUI layout view. The signal or pg option selects which type of nets to be analyzed. By default, all nets are analyzed. When this option is used, all other checking items are disabled.

Description

In a 3DIC design, multiple chips are stacked vertically or placed side by side on a silicon interposer. At the top-level of a 3DIC design, the entire chip stack is modeled as a virtual top-level design and the individual chips are modeled as cells. If you specify *-physical_contact*, the command checks the physical connections between every neighboring chip and ensures that the contacting bumps are in the correct alignment. The command checks the elevation of each chip based on the Z-value specified by the *set_cell_location* command. Chips with the same Z-value are considered to be at the same elevation and are checked for chip overlaps. Chips with adjacent Z-values are considered to be neighboring chips and are checked for physical contact. Hierarchy bumps also will be checked.

Note: The *check_3d_design* command should be used at the last step of 3DIC design flow and run at the top level.

The *check_3d_design* command writes warning and error messages that indicate potential problems in the 3DIC design. These problems might need to be corrected before manufacturing the 3DIC design. The command checks the following conditions:

- Cannot get the chip placement information
- Vertical level (Z-value) of each chip
- Chip coordinates at the top level
- Z-values of chips that do not start from 0
- Z-values of chips that are not continuous
- Chips on same level (with same Z-value) that are overlapped
- Two vertical neighboring chips are partially overlapped rather than the large chip completely covering the small chip
- Bumps are overlapped in the chip
- Non-aligned bump pairs
- Bumps do not physically connect to bump on adjacent side of vertical neighboring chip
- Bumps contact to more than one bumps of neighboring chip

Feedback

- There is no bump pair on the adjacent sides between two vertical neighboring and overlap chips
- The physical bump connections between two contacting chips do not match the logical netlist specification
- Logically connected pins of two chips on top-level design that do not have physical connected bump pairs
- Matching type mismatch between bump pairs
- Logical connected bumps or drivers on same net have different matching types
- Bump clusters have more than 1 nets
- Physical contacts are cluster inconsistent
- Chips with net to package does not have zValue = 0
- Nets on top level does not link 2 terminals
- Spacing between TSV and chip boundary violate tsvKeepoutSpacing constrain defined in tech file
- Spacing between TSV and TSV violate minCutSpacing constrain defined in tech file
- use different tech files in single die
- punch new port during the process of assign/propagate top nets

To ensure that the 3DIC design flow is successful, you should resolve any reported errors. See the man pages for the reported error message to get more information and guidance.

Prerequisites

```
create_3d_mirror_bumps
propagate_3d_connections
propagate_3d_matching_types
set_cell_location
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example performs all 3DIC checks on the design.

```
prompt> check_3d_design
```

The following example command performs a physical contact bumps check of the stacked chips.

Feedback

```
prompt> check_3d_design -physical_contact
```

---

check_advanced_boundary_cells

Checks boundary cell placement violations in a design.

Syntax

status *check_advanced_boundary_cells*

Feedback

```
[-target_objects {target_objects}]
[-include_touching_placement_blockages]
[-error_view view_name]
[-voltage_area {objects}]
```

Data Types

```
view_name   string
objects     list
```

Arguments

`-target_objects {target_objects}`

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified.

`-include_touching_placement_blockages`

Specifies that placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

`-error_view view_name`

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name.

`-voltage_area {objects}`

Specifies the voltage areas to check boundary cells.

Description

This command checks the boundary cell placement violations according to the boundary cell rules set by *set_boundary_cell_rules*. The violations can be classified as:

1. Continuity Violation: For this rule, all the boundary cells should be a complete circuit. If no, there will be a violation. If user only insert boundary cells along all the left and right edges, the boundary cells should cover all the left and right edges. If no, there will be a violation.
2. Corner And Boundary Cell Violation: This rule requires that all the corner and boundary cells are at the correct location.
3. Orientation Violation: This rule requires that all the corner and boundary cells are at the correct orientation.

Feedback

4. Short Edge And Segment Violation: This rule requires that the length of each horizontal edge of every macro (including hard keepout margin), hard placement blockage, voltage area (including guard band) must be greater than the threshold specified by the option *-min_horizontal_jog*. If not, there will be a violation. This rule also requires that the length of each segment must be greater than the threshold specified by the option *-min_row_width*. If not, there will be a violation.

This command does not check if there is no_1x violation and does not honor the following 4 options of the *set_boundary_cell_rules* command:

- -tap_distance
- -prefix
- -separator
- -do_not_swap_top_and_bottom_inside_corner_cell

Examples

The following example checks if there is any continuity violation, correct corner and boundary cell violation or correct orientation violation in current boundary cell placement.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight \\
            -top_boundary_cells myLib/CellTop \\
            -bottom_boundary_cells myLib/CellBottom
prompt> check_advanced_boundary_cells
```

See Also

- set_boundary_cell_rules
- remove_boundary_cell_rules
- report_boundary_cell_rules
- compile_boundary_cells
- compile_targeted_boundary_cells
- compile_advanced_boundary_cells
- check_boundary_cells
- check_targeted_boundary_cells

Feedback

check_alignment_marker

Checks a 3D-IC design for alignment marker. Given a design, this command checks if the design meets the requirement of the alignment marker rules.

Syntax

status *check_alignment_marker*

```
[-rules rule_list]
[-host_dies host_die_list]
[-adjacent_dies adjacent_die_list]
[-tolerance]
```

Data Types

rule_list	list
host_die_list	list
adjacent_die_list	list
tolerance	double

Arguments

`-rules`

Specify a list of alignment marker rules to check whether the current design satisfies these rules. By default, all rules within the current block will be considered.

`-host_dies`

Specify the host dies for the alignment marker rules and check if these host dies contain alignment marker cells created to satisfy all the rules listed. By default, all dies in the current design will be considered.

`-adjacent_dies`

Specify the adjacent dies for the alignment marker rules. By default, all dies in the current design will be considered. For each host die, the command will identify the suitable adjacent dies from the adjacent_die_list to check.

`-tolerance`

An error tolerance of rule checking, with a default value of 0.5, is specified.

Feedback

Description

The *check_alignment_marker* command writes warning and error messages that indicate the alignment marker violations in the 3D-IC design. The command checks the following conditions:

- The alignment marker rule cannot find any alignment marker cells that meet the criteria.
- The alignment marker cell cannot find a corresponding alignment marker rule.
- Alignment marker cells with the same reference overlap.
- When a host die has adjacent dies in multiple instantiations with the same BIT, the placement of the created alignment marker cells from the adjacent dies must be the same.
- When a host die has adjacent dies in multiple instantiations with the different BIT, the placement of the created alignment marker cells must be different.

Prerequisites

```
create_alignment_marker_rule
create_alignment_marker_cell
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

Assuming the current design includes an interposer, Die1, and Die2, where only Die1 is an adjacent die of the interposer.

When we create an alignment marker rule and the reference object of this rule is host die:

```
prompt> create_alignment_marker_rule -name AMR1 -reference_die HOST
 -type CORNER -reference_object DIE_BOUNDARY -x_offset 500 -y_offset 800
 -lib_cell AM_L -reference_corner bottom_left
```

The following example performs alignment marker checks on the interposer with rule AMR1.

```
prompt> check_alignment_marker -rules {AMR1} -host_dies {interposer}

prompt> check_alignment_marker -host_dies {interposer}
```

Feedback

When we create an alignment marker rule and the reference object of this rule is adjacent die:

```
prompt> create_alignment_marker_rule -name AMR2 -reference_die ADJACENT
 -type CORNER -reference_object DIE_BOUNDARY -x_offset 500 -y_offset 800
 -lib_cell AM_L -reference_corner bottom_left
```

The following example performs alignment marker checks on the interposer with rule AMR2.

```
prompt> check_alignment_marker -rules {AMR2}

prompt> check_alignment_marker -rules {AMR2} -host_dies {interposer}

prompt> check_alignment_marker -rules {AMR2} -host_dies {interposer}
 -adjacent_dies {Die1}

prompt> check_alignment_marker -rules {AMR2} -host_dies {interposer}
 -adjacent_dies {Die1 Die2}

prompt> check_alignment_marker -rules {AMR2} -adjacent_dies {Die1}

prompt> check_alignment_marker -rules {AMR2} -adjacent_dies {Die1 Die2}
```

See Also

- create_alignment_marker_rule
- create_alignment_marker_cell

---

check_backside_navigation

Print out the report which will specify firstly about percentage goal and window check size. Afterwards it will print out all the x and y locations or origin of vias which is not deleted and routing blockages are created their somehow.Then it will print errors for the cases in which grids no routing blockages are present.Then on the basis of ratio of valid windows to total windows it calculates the acheived percent goal.

Syntax

status *check_backside_navigation*

```
[-bbox bbox]
[-percent_goal percentage]
```

Data Types

```
bbox       rectangle
percentage             int
```

Feedback

Arguments

`-bbox` *bbox*

Specify a checking bbox. The checking window starts at the lower left of the bbox. If not specified, the whole design is used.This is an optional option. It is in format

`{{`*llx lly*`} {`*urx ury*`}}`

`-percent_goal` *percentage*

Specify targeted percent of valid windows. If not specified, value defined in app option bs_via_percent_goal is used. This is optional.

Description

Print out the report which will specify firstly about percentage goal and window check size. Afterwards it will print out all the x and y locations or origin of vias which is not deleted and routing blockages are created their somehow.Then it will print errors for the cases in which grids no routing blockages are present.Then on the basis of ratio of valid windows to total windows it calculates the acheived percent goal.

Examples

```
prompt> check_backside_navigation

#Backside Via Removal Report
#Percent Goal = 100.00%
#Check Window Size = 50.0000 x 50.0000
Error: Valid window {0.0000 0.0000} {50.0000 50.0000} does not have
 removed via. (ECO-401)
1/12 windows ( 8.33% ) have removed via: Spec is >= 100.00%
INFO: removed via Window Check Summary: NOT PASS
1
```

---

check_boundary_cells

Checks boundary cell placement violations in a design.

Syntax

status *check_boundary_cells*

```
[-error_view view_name]
[-voltage_area {objects}]
```

Data Types

```
view_name   string
objects     list
```

Feedback

Arguments

`-error_view` *view_name*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name.

`-voltage_area {`*objects*`}`

Specifies the voltage areas to check boundary cells.

Description

This command checks the boundary cell placement violations according to the boundary cell rules set by *set_boundary_cell_rules*. The violations can be classified as:

1. Continuity Violation: For this rule, all the boundary cells should be a complete circuit. If no, there will be a violation. If user only insert boundary cells along all the left and right edges, the boundary cells should cover all the left and right edges. If no, there will be a violation.
2. Corner And Boundary Cell Violation: This rule requires that all the corner and boundary cells are at the correct location.
3. Orientation Violation: This rule requires that all the corner and boundary cells are at the correct orientation.
4. Short Edge And Segment Violation: This rule requires that the length of each horizontal edge of every macro (including hard keepout margin), hard placement blockage, voltage area (including guard band) must be greater than the threshold specified by the option *-min_horizontal_jog*. If not, there will be a violation. This rule also requires that the length of each segment must be greater than the threshold specified by the option *-min_row_width*. If not, there will be a violation.

This command does not check if there is no_1x violation and does not honor the following 4 options of the *set_boundary_cell_rules* command:

- -tap_distance
- -prefix
- -separator
- -do_not_swap_top_and_bottom_inside_corner_cell

Feedback

Examples

The following example checks if there is any continuity violation, correct corner and boundary cell violation or correct orientation violation in current boundary cell placement.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight \\
            -top_boundary_cells myLib/CellTop \\
            -bottom_boundary_cells myLib/CellBottom
prompt> check_boundary_cells
```

See Also

- compile_targeted_boundary_cells
- check_targeted_boundary_cells

---

check_bufferability

Checks for a buffering supply, available lib_cells, and bufferability problems on a net segment

Syntax

status *check_bufferability*

```
[-nets net_list]
[-driver pin_or_port]
[-loads pins_or_ports]
[-hierarchy logical_hierarchy_name]
[-voltage_area voltage_area_name]
[-voltage_area_shape voltage_area_shape_name]
[-coord location]
[-verbose]
[-nosplit]
```

Data Types

net_list	collection
pin_or_port	collection
pins_or_ports	collection
logical_hierarchy_name	collection
voltage_area_name	collection

Feedback

```
voltage_area_shape_name  collection
location                 point
```

Arguments

`-nets` *net_list*

Specify net segments to check their bufferability. It can be a net name or collection. The nets must exist in the design. If this option is used, the *-driver, -loads,* and *-hierarchy* options are not needed and are ignored if specified. This command checks bufferability for only these net segments. Other segments of the same net might have different bufferability results.

`-driver` *pin_or_port*

Specify a single physical net driver; the command checks the bufferability between the driver and a set of loads in a specified hierarchy. The driver should be a leaf cell output pin, an input port of the current design, or a bidirectional leaf pin or port. It can be specified as a name or collection. The driver must exist in the design. If this option is specified, *-hierarchy* must also be specified. The driver does not have to be logically connected to the specified *-loads*, nor related to the specified *-hierarchy*. This option is ignored if used together with the *-nets* option. Without *-loads* option, it will check bufferability in target hierarchy with no loads.

`-loads` *pins_or_ports*

Specify one or more physical net loads; the command checks the bufferability between the loads and a driver in a specified hierarchy. The loads should be leaf cell input pins, output ports of the current design, or bidirectional leaf pins or ports. The loads can be specified as a list of names or as a collection. The loads must exist in the design. If this option is specified, *-driver* and *-hierarchy* must also be specified. The loads do not have to logically connected by the same net to each other or to the specified *-driver*, nor do they have to be related to the specified *-hierarchy*. This option is ignored if used together with the *-nets* option.

`-hierarchy` *logical_hierarchy_name*

Specify a logical hierarchy in which to check bufferability between a specified driver and loads. Only logical hierarchies are accepted, any leaf cell objects used with the *-hierarchy* option results in an error. The logical hierarchy can be specified as a name or a collection. The hierarchy must exist in the design. This option should be used together with the *-driver* option. The hierarchy does not have to be logically related to the specified *-driver* and *-loads*. This option is ignored if used together with the *-nets* option.

`-voltage_area` *voltage_area_name*

Specify a voltage area in which to check bufferability. This option is optional. The voltage area can be specified as a name or collection. The voltage area

Feedback

must exist in the design. The voltage area does not have to be related to the hierarchy of any of the specified *-nets, -driver, -loads,* or *-hierarchy*. If this option is not specified, it will find the native voltage area for the given nets or the given hierarchy. The option *-voltage_area*, *-voltage_area_shape* and *-coord* are mutually exclusive to each other.

`-voltage_area_shape` *`voltage_area_shape_name`*

Specify a voltage area shape in which to check bufferability. This option is optional. The voltage area shape can be specified as a name or collection. The voltage area shape must exist in the design. If secondary PG constraints are defined and a dual-rail cell is needed, the check will determine if the given VA shape has a strap available as per the secondary PG constraints. The option *-voltage_area*, *-voltage_area_shape* and *-coord* are mutually exclusive to each other.

`-coord` *`location`*

This option is optional. It takes a point consisting of a tcl list of x coordinate and y coordinate. If secondary PG constraints are defined and a dual-rail cell is needed, the check will determine if the given point has a strap available as per the secondary PG constraints. The option *-voltage_area*, *-voltage_area_shape* and *-coord* are mutually exclusive to each other.

`-verbose`

Specify that verbose output be generated. By default, *check_bufferability* gives basic information about bufferability, including the available buffering supply, number of type of available lib_cells, and whether any bufferability problems exist. In verbose mode, detailed information is reported regarding how the buffering supply is determined. Also, it prints a full list of available and unavailable lib_cells, including reasons that those lib_cells are unavailable.

`-nosplit`

Specify nosplit style reporting behavior. By default, line wrapping of long rows of data is done automatically. In nosplit mode, line wrapping is not done. Readable column alignment is still maintained in nosplit mode.

Description

=== Summary ===

The *check_bufferability* command checks net bufferability. Use this command to understand the following information about a net:

- What supply net is used for buffering
- Whether single rail, dual rail, or insulated dual rail buffers are used for buffering

Feedback

- How many and which buffer and inverter lib_cells are available for buffering the net
- Whether there are design constraints or other factors that would prevent buffering, despite an available buffering supply and available lib_cells

=== Use Models ===

There are two use models for calling *check_bufferability*:

check_bufferability -nets [-voltage_area|-voltage_area_shape|-coord]

check_bufferability -driver [-loads] -hierarchy [-voltage_area|-voltage_area_shape|-coord]

In the first use model, the *-nets* option specifies net segments on which to check bufferability. A net might consist of many logical segments, which can be accessed using *get_nets -segments*. Bufferability can be different for each net segment, so it is important to specify the correct net segment to get back correct bufferability results. To get a full understanding of the bufferability of the entire net, it might be necessary to call *check_bufferability* multiple times on different net segments. Reasons that bufferability can change for different segments of the same net include:

- The net crosses into different power domains and voltage areas. Each power domain can have different primary and available supplies. So, the net segments of one power domain might be bufferable using single rail buffers with the domain primary supply, but dual rail buffers are needed for the segments of a different power domain.
- The fanouts of the net segments change. For example, in a switched domain, one net segment might fanout to a switched load and an always-on load, requiring dual rail buffering to reach the always-on load. But, querying a different net segment that only fans out to the switched load shows that single-rail buffers can be used.
- Design constraints are present that affect net segments or hierarchies differently. For example, *set_dont_touch* constraints can be applied to some net segments but not others. Another example is *set_target_library_subset* constraints that restrict available lib_cells in different logical hierarchies. Either of these constraints can cause one segment of a net to be unbufferable while other segments remain bufferable.

In the second use model, the *-driver* and *-loads* options are used to specify a net driver and one or more net loads which must be buffered. This approach can be used to do a more restricted bufferability query on a net than using the *-nets* option. For example, if using *-nets* shows the net has no available buffering supply, you can use *-driver* and *-loads* to remove some of the loads from consideration, and see if the net is bufferable for the remaining loads.

The *-driver* and *-loads* options can also be used to perform a hypothetical bufferability query between a certain set of related supplies. The specified driver and loads do not have to belong to the same net, or hierarchy, or voltage area. You can specify any arbitrary drivers and loads in the design. When making such a hypothetical query, you are asking

Feedback

"what is the bufferability of a net with the same related supply as the specified driver, going to loads with the same related supplies as the specified loads?"

When using the *-driver* and *-loads* options you must also use the *-hierarchy* option. This specifies which logical design hierarchy in which to check bufferability. This information is required to do an accurate bufferability query, because things like target library subset constraints or bias optimization have hierarchy dependent impact on bufferability.

When using *-driver, -loads,* and *-hierarchy*, the command tries to identify a real net segment in the design that corresponds to those specified options. If it finds one, then it prints an information, and can perform the full range of bufferability checks. If the command cannot identify a real net segment, then certain bufferability checks like dont_touch and is_ideal cannot be performed, since they are associated with net segments.

When using *-driver* and *-hierarchy* without *-loads* option, it specifies a special situation for a hypothetical or real dangling net without any loads.

In both use models, the voltage area is very important, as it defines the primary supply and available supplies that could be used for buffering. Without *-voltage_area* option, the command will choose native voltage area of the given net or hierarchy.

You can check bufferability either in the native voltage area of the net or in any arbitrary voltage area. Normally, buffers can only be physically placed in the voltage area that is native to the net segment being buffered. By enabling the physical feedthrough buffering feature, you can disconnect the logical from the physical and allow buffers to be placed in voltage areas non-native to the net segment hierarchy. This is enabled by:

set_app_options -name opt.common.allow_physical_feedthrough -value true

create_voltage_area_rule -allow_physical_feedthrough true

By enabling the logical feedthrough buffering feature, you expect buffers are placed in the new hierarchy. The new hierarchy is non-native for the given net segment, but native for the given voltage area. Furthermore, additional new hierarchical ports need to be punched from net segment hierarchy to new hierarchy to connect the buffers. This is enabled by:

create_voltage_area_rule -allow_logical_feedthrough true

If you use *check_bufferability* to query a net segment that exists in a logical hierarchy that is not native to the specified voltage area, this implies that you are doing a logical or physical feedthrough buffering query. *check_bufferability* issues a warning if such a query is done when both logical and physical feedthrough buffering are set to false.

=== Buffering Supply Availability ===

The first thing checked by *check_bufferability* is the supply net availability for buffering. Supply availability is determined first by finding the related supply of the driver pin and all load pins. You can manually check this using the *get_related_supply_nets* command. The

Feedback

set of candidate supplies for buffering is all the related supplies of the driver and loads of the net, plus their PST-equivalent supplies. This set of candidates is then filtered based on the supply availability in the specified voltage area. Finally, a buffering supply is selected from among the candidate supplies that meets these criteria:

- Does not introduce an isolation violation between the driver and any of the loads. To satisfy this condition, the chosen supply must be less-than-or-equal-on compared to the driver supply, and more-than-or-equal-on compared to all load supplies
- Does not introduce a voltage shifting violation
- Single rail buffering is preferred to dual rail buffering, so the domain primary supply is chosen if possible

This process is used for determining the buffering supply of most nets. Some nets have special loads that require a different approach. These special loads include isolation cells, enable level-shifters, and overdriven level shifters. The related supply of these special cell inputs is invalid -- it is just the same as the output related supply. To guarantee that no MV violation is introduced, the buffering supply is restricted to only the driver supply for such nets. Using any other supply risks introducing an MV violation that cannot be detected until simulation is run on the output netlist from IC Compiler II.

check_bufferability reports the results of the supply availability check as a set of supplies that can be used: power, ground, as well as nwell and pwell supplies for bias designs. It also reports the type of buffer needed to use those supplies:

- Single rail: If the buffering power supply is the domain primary power supply
- Dual rail: If the buffering power supply is not the domain primary power supply
- Insulated dual rail: For bias design only, when a dual rail buffer is needed and the required backup supply for the buffer is more on than the domain primary nwell supply

As previously mentioned, which net segment is queried by *check_bufferability* is critical to the results of the buffering supply availability check. To get a complete picture of net bufferability, it is important to query a net segment from each power domain that the net logically enters. The first net segment encountered in each power domain is typically the most useful to query. It will give the most pessimistic result, since it will have the most load fanouts that could have different or even conflicting related supplies. Also, in most cases, it is most representative of what the data or CTS buffering engines will see for the available buffering supply.

By default, *check_bufferability* prints a one line summary message that gives the buffering supply information. To get more detailed information about the related supplies and special MV characteristics of any of the driver or load pins, use the *-verbose* option.

=== lib_cell Availability ===

Feedback

If a valid buffering supply is determined, then *check_bufferability* next evaluates available lib_cells that can be used to buffer the net. If no valid buffering supply is determined, then lib_cell checking cannot be performed, and *check_bufferability* issues a warning.

check_bufferability evaluates every buffer and inverter lib_cell in the libraries as candidates for buffering the net. There are 7 reasons that a buffer or inverter cannot be used:

1. lib_cell purpose exclusion: The lib_cell has been excluded based on the *set_lib_cell_purpose* settings. *check_bufferability* uses an appropriate lib_cell purpose for querying buffering, depending on which engine can do high-fanout buffering for the net. It uses *optimization* purpose for data nets, *cts* purpose for clock nets, *cts* purpose for mixed clock and data nets that have been correctly isolated by the tool using clock/data isolation buffers, and both *optimization* and *cts* purpose for any mixed clock and data nets that have not been isolated from each other. You can use *report_mv_lib_cells* to identify valid purposes for library cells.
2. dont_touch constraint: If *set_dont_touch* is applied on the lib_cell, it cannot be used for buffering. You can use *set_attribute [get_lib_cells] dont_touch false* or *set_dont_touch [get_lib_cells] false* to remove dont_touch from required library cells.
3. Target library subset exclusion: *set_target_library_subset* constraints exclude this lib_cell from being used in the hierarchy of the *-nets* or *-hierarchy* option. Please, use *report_target_library_subset* to identify exclusion of library cells.
4. site_def mismatch: The site_def of the lib_cell doesn't match the site_def of any site_rows in the specified voltage area. This can also occur if the site_def names match, but the characteristics are mismatched, like if the height of the lib_cell site_def and site_row site_defs is mismatched. To manually check site_def information, use the site_def attribute on lib_cell, site_row, or site_array objects.
5. Bias mismatch: This occurs for lib_cells that don't match the bias context. For example, any lib_cells without nwell and pwell pg_pins would be rejected for use in a bias block. Similarly, insulated dual-rail lib_cells would be excluded if regular dual-rail lib_cells are required. You can use *report_mv_lib_cells –buffer / -inverter –verbose* to get bias information (insulated/non-insulated) for library cell.
6. Voltage mismatch: The lib_cell pg_pin voltage doesn't match that required by the buffering supply. For example, the net needs to be buffered with a 1.0V supply, but the lib_cell supply is 2.0V.
7. Incompatible supply rails: This usually occurs if the number of pg_pins on the lib_cell doesn't match what is expected. For example, if a single-rail buffer is needed, then dual-rail buffers are rejected due to the extra backup power pin.

Feedback

check_bufferability reports the lib_cell availability as a count of available buffers and inverters on the same summary line that shows the buffering supply information. For example:

```
Information: Can insert single rail buffers (25 lib_cells) and inverters
 (33
lib_cells) with supply nets (power: VDD, ground: VSS). (MV-453)
```

To get more detailed information that lists every available buffer and inverter, as well as every unavailable buffer and inverter including the reason that it is unavailable, use the *-verbose* option.

=== Bufferability Problems ===

After performing buffering supply checking and lib_cell availability checking, *check_bufferability* also checks for buffering problems related to design constraints and other factors. Any of these that occur are listed as part of the standard output of *check_bufferability* under the 'Bufferability Problems' section. These reasons are:

- The net has no driver
- The net has multiple drivers
- The net is dont_touch
- The net is ideal
- The net is driven by constant 1 or 0
- The net is tri-state
- The net belongs to a read-only block
- The net is not in the block of the given voltage area
- The net's hierarchy is not in the domain scope of the given voltage area
- Freeze ports are found and not able to find LFT hierarchy
- No LFT buffer insertion is allowed for the given voltage area, please check its voltage area routing rule.
- Logical or physical feedthrough buffering must be enabled to buffer the net in the given voltage area
- No legal supply nets are available for buffering
- No legal supply nets are available for buffering: nwell/pwell supply nets are less on than primary power/ground for the given voltage area
- No legal lib cells are available for buffering

Feedback

In some cases, all of these checks cannot be performed. *check_bufferability* always prints a warning if any checks are skipped.

The 'No legal supply nets area available for buffering' message occurs if the buffering supply checking fails. In this case, lib_cell availability checking is skipped.

The 'No legal lib cells are available for buffering' message occurs if 0 buffers and 0 inverters are available based on the lib_cell availability checking.

Checking of net dont_touch and is_ideal properties can only be done if a real net segment is identified by the command. They are skipped if the *-driver* and *-hierarchy* options are used to perform a hypothetical bufferability query.

If the net has no driver, then supply net availability and lib_cell availability checking is skipped.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

Examples

Check bufferability for all net segments with prefix SNPS in native voltage area.

```
prompt> check_bufferability -nets [get_nets -hierarchical {SNPS*}]
```

Check bufferability for net n1 in voltage area VA1. It is bufferable with single rail buffers.

```
prompt> check_bufferability -nets n1 -voltage_area VA1

Information: Can insert single rail buffers (8 lib_cells) and inverters
 (6
lib_cells) with supply nets (power: VDD1, ground: VSS). (MV-453)
```

Check bufferability for net n2 in voltage area VA2. It is bufferable with dual rail buffers.

```
prompt> check_bufferability -nets n2 -voltage_area VA2

Information: Can insert dual rail buffers (14 lib_cells) and inverters
 (14
lib_cells) with supply nets (power: VDD2, ground: VSS). (MV-454)
```

Check bufferability for net n3 in voltage area VA3. It is not bufferable because there are no lib_cells available for buffering. But, a valid supply for dual rail buffering is found.

```
prompt> check_bufferability -nets n3 -voltage_area VA3

Information: Cannot insert dual rail buffers or inverters because of no
```

Feedback

```
available lib_cells. But required supply nets (power: VDD3, ground: VSS)
 are
available. (MV-457)
```

Check bufferability for net n4 in voltage area VA4. It has a valid buffering supply and available lib_cells, but is not bufferable for other reasons.

```
prompt> check_bufferability -nets n4 -voltage_area VA4

Information: Cannot insert buffers or inverters because of non-MV
 reasons. But
single rail buffers (12 lib_cells) and inverters (14 lib_cells) with
 supply
nets (power: VDD4, ground: VSS) are available. (MV-463)
```

---

check_bump_spacing

Check spacing among bumps.

Syntax

status *check_bump_spacing*

```
[-reference_cells ref_cell_list]
[-report]
[-min_spacing distance]
[-max_count number]
[-distance_style flyline_distance | manhattan_total | manhattan_max]
[-error_view view_name]
```

Feedback

Data Types

```
ref_cell_list list
distance      float
number        integer
view_name     string
```

Arguments

`-reference_cells` *`ref_cell_list`*

Specifies the referene of bump cells to be considered during current run. If this option is not specified, all bump cells are considered.

`-report`

If selected, the command will report bump location statistics. No checking will be performed.

`-min_spacing` *`distance`*

Specifies the minimum allowable distance. This option must be used for bump spacing checking. This option cannot be used with *-report* option.

`-max_count` *`number`*

Specifies the maximal numebr of violations to be reported. This option cannot be used with *-report* option. The default value is 10.

`-distance_style` *`flyline_distance`* | *`manhattan_total`* | *`manhattan_max`*

Specifies how the distance is computed. If *flyline_distance* is chosen, the distance is the distance bwtween the centers of the two bumps. If *manhattan_total* is chosen, the distance is the Manhattan distance bwtween the centers of the two bumps. If *manhattan_max* is chosen, the distance is either the horizontal or vertical distance, whichever is larger, bwtween the centers of the two bumps. The default choice is *flyline_distance*.

`-error_view` *`view_name`*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file.

Description

This command reports the spacing among bumps or violations of bump spacing. The distance between a pair of bumps is computed using the corresponding centers of the bumps.

Feedback

Examples

The following command reports the bump spacing.

```
prompt> check_bump_spacing -report
```

The following command reports whether there exists pairs of bumps whose distance is less than 10 micron. At most 100 violations will be reported.

```
prompt> check_bump_spacing -min_spacing 10 -max_count 100
```

See Also

- create_bump_array

---

check_bump_terminals

Terminal-centric bumps must not have pins connected to nets. Assigned bumps will have their terminal associated with a port. This command checks all bumps for incorrect net connections and all violating bumps should be reported with the pin and connected net name.

The check is made if the app option plan.3dic.bump_model is set to terminal. If it is set to net the command exit with a NDMUI-1148 message that the design is using the net-centric bump model and no check is made

Syntax

collection *check_bump_terminals*

Description

This command checks each terminal-centric bump terminal on each port on a block and flag any logical net connection.

Examples

The following example reports bump terminal with net connections.

```
prompt> check_bump_terminals
```

See Also

- create_terminal
- convert_bump_terminals
- plan.3dic.bump_model

Feedback

check_busplan_constraints

Checks the validity of the current busplan constraints defined by the *set_busplan_constraints* command.

Syntax

```
status check_busplan_constraints
[-ref_buses]
[-check_ref]
[buses]
```

Data Types

buses	string

Arguments

`-ref_buses`

Returns a list of "referencing" busplans, based on the list of passed-in buses. If bus1 is referenced by bus2 specified with the *set_busplan_constraints -from bus2 -to bus1 -type equal* command, then *check_busplan_constraints -ref_buses bus1* will return the list containing bus2.

`-check_ref`

Checks the constraints of the referencing buses instead of checking the constraints of the passed-in buses.

The following command:

```
set result [check_busplan_constraints -check_ref $busList]
```

is equivalent to these commands:

```
set refList [check_busplan_constraints -ref_buses $busList]
set result [check_busplan_constraints $refList]
```

By default, the command checks the constraints of the passed-in buses.

`buses`

Specifies the names of busplans to check for constraint validity. The buses must be created with the *create_busplans* command.

Description

Checks the validity of current busplan constraints as previously defined by the *set_busplan_constraints* command. The result will be a Tcl list containing 2 Tcl sub-lists. The first sub-list contains a list of busplans that are currently failing to match their

Feedback

constraint. The second sub-list contains a list of busplans that will potentially fail to match their constraints, given the current suggestions from pipeline register planning.

For example, suppose bus1 has the constraint <= 3, and is included in the "buses" parameter.

If bus1 has had 4 virtual registers inserted for planning purposes, then bus1 will be included in the first sub-list, since the current situation fails the constraint (n <= 3) and the second sub-list, since it is also potentially failing in the current state.

On the other hand, if bus1 has had no virtual register inserted, but planning computations suggests bus1 needs 4 or more registers total to meet timing, bus1 will be placed into the second sub-list only. The bus currently meets its constraint, however, following the planning suggestions will cause it to fail its constraint. If bus1 can meet timing with 1, 2 or 3 virtual registers (whether inserted or computed), the constraint will be considered met and bus1 will not be included in either sub-list.

Examples

Create a constraint for a busplan named bus1, and check the constraint. Assume busplan bus1 needs 2 registers to meet timing. In this example, the 2 registers are inserted with the *modify_busplan* command.

```
prompt> set_busplan_constraints -from bus1 -to_value 2 -type equal
1
prompt> check_busplan_constraints bus1
{} {}

# Add 2 virtual registers
prompt> modify_busplan -add_register -after group1 \\
   -location {100 100} bus1
{register1}
prompt> modify_busplan -add_register -after group1 \\
   -location {100 100} bus1
{register2}

# If timing is met
prompt> check_busplan_constraints bus1
{} {}

# If timing is not met
prompt> check_busplan_constraints bus1
{} {bus1}

# Insert another register
prompt> modify_busplan -add_register -after group1 \\
   -location {100 100} bus1
{register3}

prompt> check_busplan_constraints bus1
{bus1} {bus1}
```

Feedback

---

check_cap_cells

Checks a 3D-IC design for embedded deep trench capacitor (eDTC) cells. Given a design, this command validates that the design meets the requirements of the deep trench capacitor rules and reports violations.

Syntax

status *check_cap_cells*

```
-cap cap_lib_cell_name
-vdd vdd_lib_cell_name
-vss vss_lib_cell_name
-filler filler_lib_cell_name
[-rules rule_list]
[-verbose]
[-fishbone_area bbox]
```

Data Types

cap_lib_cell_name	string
vdd_lib_cell_name	string
vss_lib_cell_name	string
filler_lib_cell_name	string
rule_list	list
bbox	bounding box

Arguments

`-cap cap_lib_cell_name`

Specify the library cell name for the capacitor cells. This is a required option that defines the reference capacitor cell design to be used for validation.

Feedback

`-vdd vdd_lib_cell_name`

Specify the library cell name for the VDD cells. This is a required option that defines the reference VDD cell design to be used for validation.

`-vss vss_lib_cell_name`

Specify the library cell name for the VSS cells. This is a required option that defines the reference VSS cell design to be used for validation.

`-filler filler_lib_cell_name`

Specify the library cell name for the filler cells. This is a required option that defines the reference filler cell design to be used for validation.

`-rules rule_list`

Specify a list of capacitor cell rules to check whether the current design satisfies these rules. By default, all cap cell rules within the current block will be considered. The rule_list should contain cap_cell_rule objects.

`-verbose`

Enable verbose reporting mode. When specified, all error messages will be displayed. Without this option, only the first 10 error messages of each type will be shown.

`-fishbone_area bbox`

Specify the bounding box area for fishbone pattern insertion checking. By default, the entire block boundary will be used as the fishbone area.

Description

The *check_cap_cells* command validates eDTC cell placement and configuration in 3D-IC designs. The command performs comprehensive checks to ensure the DTC implementation meets design rules and constraints.

Group Definitions

The command uses the following group definitions for validation:

- "*VSS Pin Group*:" A collection of all horizontally continuous VSS, CAP, and filler cells. These groups are formed by identifying cells that are horizontally adjacent and form a continuous row structure.
- "*CAP Group*:" A collection of all CAP cells that are adjacent in both horizontal and vertical directions and do not violate unit offset constraints. These groups represent connected regions of CAP cells that must satisfy area and continuity requirements as a unit.

Feedback

The command validates the following aspects of the eDTC placement:

- *Cell Library Validation*: Verifies that the specified capacitor, VDD, VSS, and filler library cells exist and are properly defined.
- *Unit Offset Checking*: Validates that DTC cells are placed with proper unit spacing and alignment in both horizontal and vertical directions.
- *VSS Pin Group Validation*: Creates and validates VSS pin groups, ensuring that each group contains the required VSS and capacitor cells, and checks distance constraints between each CAP cell and VSS cells.
- *VDD Integration Checking*: Verifies that VSS pin groups have proper VDD cell associations and that VDD cells are correctly positioned relative to the groups in fishbone scenario.
- *CAP Group Analysis*: Creates CAP groups and checks for violations including area constraints, width constraints, height constraints, and cap void area constraints.
- *Spacing Validation*: Performs two types of spacing checks:
  - *CAP Spacing*: Validates minimum spacing requirements between CAP groups.
  - *TSV Spacing*: Validates minimum spacing between all cells (CAP, VDD, VSS, filler) and TSV (Through-Silicon Via) structures.
- *Density Reporting*: Analyzes and reports the density of DTC cells across the design region, considering power grid stripes and layout constraints.

The command generates detailed reports of any violations found, including spatial coordinates and specific rule violations. Error messages are categorized by type and severity to help designers identify and resolve issues efficiently.

When violations are detected, the command creates error data that can be viewed in the Error Browser, allowing for visual inspection and debugging of problematic areas.

Examples

Check DTC cells using specific library cell names:

```
prompt> check_cap_cells -cap my_cap_cell -vdd my_vdd_cell -vss
 my_vss_cell -filler my_filler_cell
```

Check with verbose output and specific rules:

```
prompt> check_cap_cells -cap cap_lib -vdd vdd_lib -vss vss_lib -filler
 fill_lib -rules {rule1 rule2} -verbose
```

Check with a specific fishbone area:

```
prompt> check_cap_cells -cap cap_cell -vdd vdd_cell -vss vss_cell -filler
 filler_cell -fishbone_area {{100 100} {1000 1000}}
```

Feedback

Returns

Returns *OK* if the checking process completes successfully, regardless of whether violations are found. Returns *Error* if there are issues with the command arguments, missing library cells, or other fatal errors that prevent the checking process from completing.

NOTES

If cap cell rules exist in the design block, the command will use the reference cells defined in those rules as defaults. If no rules are present, default rule setting will be considered.

The command requires a valid current design block and will fail if no block is available or if the specified library cells cannot be found in the current library.

See Also

- create_cap_cells

---

check_clock_gate_library_cell_availability

Checks whether there are ICG library cells available for clock gate insertion in the design.

Syntax

status *check_clock_gate_library_cell_availability*

```
[-objects object_list]
[-verbose]
```

Data Types

```
object_list            list
```

Arguments

`-objects object_list`

Specifies the objects on which the check will apply. Valid objects are hierarchical instances, power domains and designs. The check will be performed on all the hierarchical instances assciated with the objects in *object_list*. If the option is not used, the check will be performed on all the hierarchical instances in the current design.

`-verbose`

Shows more information for every hierarchical instance on which the check failed.

Feedback

Description

This command will check whether there are ICG library cells available, according with the current library constraints and clock gate style settings, for every hierarhical instance indicated in parameter *-objects*, or in the entire design.

The command will succeed (and return 1) if all the checked hierarchical cells have ICG library cells available for clock gate insertion.

The command will fail (and return 0) if at least one hierarchical cell exists with no ICG library cells available for insertion.

ICG library cells in the library can be rejected because of the following reasons:

- General Reasons, which apply to the entire design. • [LIBRARY]

```
1. "it is a dont_touch libcell or it does not match the expected
 libcell purpose".
```

- Instance-specific Reasons, which depends on the hierarchical cell. • [STYLE]

```
2. "it has no te port when required"
3. "it has no obs port when required"
4. "its en port does not match active high/low requirements => it is
    active high, when active low was expected" or vice versa.
5. "its te port does not match active high/low requirements => it is
    active high, when active low was expected" or vice versa.
6. "its clk output port does not match inversion requirements => it is
    inverted, when non-inverted was expected" or vice versa.
7. "its obs port does not match inversion requirements => it is
 inverted,
    when non-inverted was expected" or vice versa.
8. "it does not match sequential/latch requirements => it is
 latch-based,
    when latch-free was expected" or vice versa.
9. "it does not match edge requirements => it is rising edge, when
    falling edge was expected" or vice versa.
10. "it does not match pre/post control requirements => it is
 pre-control,
    when post-control was expected" or vice versa.
```

- [OPCONDS]

```
11. "it does not match hierarchy operating conditions".
```

Examples

The following example shows the output in case of success on all the hierarchies in the design.

```
prompt> check_clock_gate_library_cell_availability
There are ICG library cells available on all hierarchies. (CGT-4303)
1
```

Feedback

The following example shows the output in case of success on objects mid1 and mid2.

```
prompt> check_clock_gate_library_cell_availability \\
   -objects [get_cells {mid1 mid2}]
There are ICG library cells available on all objects. (CGT-4303)
1
```

This example shows the output in case of failure when there are no ICG library cells in the libraries.

```
prompt> check_clock_gate_library_cell_availability
Warning: There are no ICG library cells available in the library.
 (CGT-3301)
0
```

This example shows the output in case of failure when there are no ICG library cells for instance mid1 and mid2.

```
prompt> check_clock_gate_library_cell_availability \\
   -objects [get_cells {mid1 mid2 mid3}]
Warning: There are no ICG library cells available for hierarchical cell
   mid1. (CGT-3302)
Warning: There are no ICG library cells available for hierarchical cell
   mid2. (CGT-3302)
0
```

This example shows the verbose output in case of failure when there are no ICG library cells for instance mid1 and mid2, after setting a clock gate style that requires observation output, when some of the library cells are restricted and the remaining do not have observation output port.

```
prompt> set_clock_gate_style -observation_output \\
   -target {neg_edge_flip_flop pos_edge_flip_flop} \\
   -objects [get_cells {mid1 mid2 mid3}]
1
prompt> check_clock_gate_library_cell_availability \\
   -objects [get_cells {mid1 mid2 mid3}] \\
   -verbose
Some hierarchies have no ICG libcells available. (CGT-4304).
ICG library cell tcbn90ghvtbc/CKLHQHVTD1 cannot be used for all-designs
   because it is a dont_touch libcell or it does not match the expected
   libcell purpose. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD2 cannot be used for all-designs
   because it is a dont_touch libcell or it does not match the expected
   libcell purpose. (CGT-4305)
ICG library cell tcbn90ghvtbc/CKLHQHVTD3 cannot be used for all-designs
   because it is a dont_touch libcell or it does not match the expected
   libcell purpose. (CGT-4305)
Warning: There are no ICG library cells available for hierarchical cell
   mid1. (CGT-3302)

- set_clock_gate_style

---

check_clock_trees

Checks the clock trees of current design for possible problems with netlist, timing constraints, clock constraints, routing constraints, or other tool configurations that can adversely impact clock tree synthesis.

Syntax

status *check_clock_trees*

```
[-clocks clock_list]
[-message_limit number]
[-include_ccd_checks]
```

Data Type

object_list	list or collection
number	integer

Arguments

`-clocks clock_list`

Checks only those clock trees that appear in the clock_list. By default, the command checks all clocks in the design.

`-message_limit number`

Specifies the number of messages to be printed in each checks detail report. Default all of the messages will be printed. Number should be greater than 0

Feedback

`-include_ccd_checks`

Performs the concurrent clock and data optimization related checks on clock trees for possible problems with user specified constraints or settings or other configurations that can adversely impact concurrent clock and data optimization behaviour.

Description

Use the check_clock_trees command before clock tree synthesis to check for common problems that might impact clock tree synthesis.

---

check_consistency_settings

Compares the settings between this tool and the PrimeTime, StarRC, PrimePower, or IC Compiler tool for good timing correlation between the two tools, and between Fusion extraction and StarRC In-Design extraction settings.

Syntax

status *check_consistency_settings*

```
[-tool type]
[-work_dir path_name]
[-output filename]
[-script filename]
[-apply]
```

Data Types

```
type        string
path_name   string
filename    string
```

Arguments

`-tool`

Indicates the target tool to check against. Valid values are pt, icc, icc2, pp/primepower, starrc and fusion_extraction.

`-work_dir`

Specifies the directory that contains the scripts to check. If the script file specified by the *set_consistency_settings_options* command includes some nested scripts, you must use this option to ensure those nested scripts can be sourced correctly. If the specified tool is fusion_extraction, this option is not needed.

Feedback

`-output`

Specifies the output file to use to save the correlation checking result. If the specified tool is fusion_extraction, this option is not needed.

`-script`

Specifies the output file to use to save the tcl file which make ICC2 RC extraction setting the same as StarRC. If the specified tool is fusion_extraction, this option is not needed.

`-apply`

When this option is used, the command will not only report differences but will also update all the differences. The current value of all the app options which are different will be copied from the specified tool to the current tool.

Description

The *check_consistency_settings* command compares the settings between this tool and the PrimeTime, StarRC, PrimePower, or IC Compiler tool for good timing correlation between the two tools. The command reports an error for each setting that is different from the recommended setting and reports the proper setting in the applicable tool. It also compares the settings between Fusion extraction and StarRC In-Design extraction.

Before using this command, run the *set_consistency_settings_options* command to set up the executable location and setup script. If the speficied tool is fusion_extraction, this step is not needed.

Multicorner-Multimode Support

This command applies only to current scenario for timing correlation checking, or applies to the *-corner* and *-early* options of *set_consistency_settings_options* command for extraction correlation checking.

Examples

The following example uses the *check_consistency_settings* command to check consistency between this tool and the PrimeTime tool. The *set_consistency_settings_options* command sets up the executable location and related setup script such as pt.tcl.

```
prompt> set_consistency_settings_options \\
   -exec_path /software/syn/bin -tool pt -script pt.tcl
prompt> check_consistency_settings -tool pt
Error: The timing_remove_clock_reconvergence_pessimism setting is
  inconsistent between Fusion Compiler and PrimeTime. The Fusion Compiler
  value is TRUE; the PrimeTime value is "false". (CORR-803)
Error: The timing_remove_clock_reconvergence_pessimism PrimeTime variable
should be set to TRUE. (CORR-800)
```

Feedback

The following example uses the *check_consistency_settings* command to check consistency between the tool and the StarRC tool. The *set_consistency_settings_options* command sets up the executable location and related setup script such as starrc.tcl.

```
prompt> set_consistency_settings_options \\
   -exec_path /software/syn/bin -tool starrc -script starrc.tcl \\
   -corner maxCorner
prompt> check_consistency_settings -tool starrc
Error: The temperature(OPERATING_TEMPERATURE) setting is inconsistent
   between Fusion Compiler and StarRC. The Fusion Compiler value is 25;
   the StarRC value is 0.00. (CORR-803)
Error: The virtual_shield_extraction Fusion Compiler setting should be
 set
   to FALSE. (CORR-812)
Error: The TEMPERATURE_SENSITIVITY StarRC setting should be set to NO.
   (CORR-800)
```

The following example uses the *check_consistency_settings* command to check consistency between this tool and the PrimePower tool. The *set_consistency_settings_options* command sets up the executable location and related setup script such as pp.tcl.

```
prompt> set_consistency_settings_options \\
   -exec_path /software/syn/bin -tool pp -script pp.tcl
prompt> check_consistency_settings -tool pp
Error: The
 power.default_static_probability(power_default_static_probability) is
  inconsistent between Fusion Compiler and PrimePower. The Fusion
 Compiler
  value is 0.2(recommended-value is '0.5'); the PrimeTime value is
 0.1(recommended-value is '0.5'). (CORR-803)
```

- set_consistency_settings_options

---

check_design

Runs pre-defined or user-defined checks on current design. Messages generated by the checks run, are captured into an EMS database file and also into a text log file. Summary of the messages generated is also reported.

Syntax

status *check_design*

```
-checks        names_of_checks
[-ems_database ems_database_name]
[-open_message_browser]
[-log_file log_file_name]
```

Feedback

Data Types

```
names_of_checks      list
ems_database_name    string
```

Arguments

`-checks` *names_of_checks*

List of the names, of one or more user-defined or pre-defined checks, which will run on the current design.

A check pre-defined by the tool is called a pre-defined check. Examples of pre-defined checks are *pre_route_stage*, *mv_design*, *clock_trees*, *hier_timing*, *hier_pre_placement* etc. An user can create her own check with *create_check_design_strategy* command, which are called user-defined checks. User can get the list of all pre-defined and user-defined checks by invoking *get_design_checks* command.

Check *mv_design* is called an atomic-check since it is defined using a single UI command *check_mv_design*. Check *pre_route_stage* is called a mega-check since it is defined as a collection of atomic-checks.

Checks *pre_placement_stage*, *pre_clock_tree_stage* and *pre_route_stage* are the three available pre-defined mega-checks. Check *pre_placement_stage* can be run on a design in pre-placement stage. Similarly, checks *pre_clock_tree_stage* and *pre_route_stage* can be run on a design in pre-clock-tree stage and pre-route stage respectively.

There are several pre-defined atomic-checks like *mv_design*, *routability*, *clock_trees*, *hier_timing*, *hier_pre_placement* etc., which can be run by the user based on her requirements at different stages of design.

Below is a list of pre-defined atomic checks and mega-checks. You can run get_design_checks command to get this list as well.

Atomic-checks: cts_qor, legality, rp_constraints, feedthroughs, mib_alignment, finfet_grid, pin_placement, routes, physical_constraints, dp_pre_floorplan, dp_pre_create_placement_abstract, dp_pre_block_shaping, dp_pre_macro_placement, dp_pre_power_insertion, dp_pre_pin_placement, dp_pre_push_down, dp_pre_create_timing_abstract, dp_pre_timing_estimation, dp_pre_budgeting, dp_pre_clock_trunk_planning, dp_floorplan_rules, mv_design, routability, clock_trees, scan_chain, design_mismatch, analyze_design_violations, timing, hier_timing, hier_pre_placement, hier_pre_clock_tree, hier_pre_route, hier_pre_compile, block_ready_for_top, netlist, 3d_netlist, unbound, design_states.

Mega-checks: pre_placement_stage, pre_clock_tree_stage, pre_route_stage.

Feedback

`-ems_database` *`ems_database_name`*

Name of EMS database which will store the Error, Warning and Info messages generated by the checks.

If this option is not specified, then by default, "check_design.ems" is used as the name of EMS database and if an EMS database by name "check_design.ems" already exists, then its contents will be overwritten.

The EMS database name can contain only alpha-numeric characters and underscore character("_"). User is expected to provide the EMS database name with suffix ".ems". If user does not provide the suffix ".ems", then suffix ".ems" will be appended to the given name, automatically by the command, and used as EMS database name.

`-open_message_browser`

Opens the message browser window in GUI, which displays the messages captured in the EMS database.

`-log_file` *`log_file_name`*

Name of the log file to which the messages are output into. Both relative path and absolute path are supported. User needs to ensure the specified path and file is writable. If the file is already there, it will be overwritten. By default, check_design outputs logs into auto-generated file check_design***.log in the working directory, in which *** is the timestamp.

Description

This command is an unified framework to perform design checks. The command writes the Error, Warning and Info messages generated by running checks on design, to Enhanced Messaging System(EMS) database file and into a text log file. All the messages generated by the checks are captured into text log file. Only a sub-set of messages generated are captured into EMS database. The messages NOT captured into EMS database are referred to as Non-EMS messages. Summary information is displayed by the command to indicate the number of EMS and Non-EMS messages along with their message-ids and message templates.

To look into the Error, Warning and Info messages generated by the checks and debug the issue, one can open the EMS database in GUI, by opening message browser window. If user does not prefer GUI then the messages can be viewed in text log file. The name of the log file is time-stamp based and a new log file is generated for every run of *check_design* command. The log file name is of the form "check_design<T>.log", where "<T>" indicates the time-stamp. The log file is saved in the current directory.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information. But checks run by the command may depend on scenario-specific information.

Feedback

Examples

The following example runs the predefined mv_design atomic check.

```

check_design_for_clock_trunk_planning

Check the design for CTP feasibility.

Syntax

```
status check_design_for_clock_trunk_planning
[-clock clock_list]
[-summary]
```

Data Types

```
clock_list       collection
```

Arguments

`-clock clock_list`

Specifies the clocks for which clock trunk planning checker is to be run. By default, all clocks are checked.

`-summary`

This boolean argument specifies if the summary report is to be printed.

Description

This command runs the CTP related checks from top.

Feedback

Examples

The following example runs CTP checker for clock 'clk1' and also prints the summary.

```
prompt> check_design_for_clock_trunk_planning -clock clk1 -summary
```

See Also

- check_hier_design

---

check_design_states

Checks design states of current block like linked, mapped.

Syntax

status *check_design_states*

```
[-verbose]
```

Arguments

`-verbose`

Prints the unmapped cells information.

Description

This command checks the linked and mapped design states of the current design. This command will print whether the design is linked or not and the mapped percentage of the cells of the current design.

When command option *-verbose* is specified the command will report the unmapped cells information.

This command has no dependency on scenario-specific information.

Examples

The check_design_states command displays the following information when no option is specified.

```
prompt> check_design_states
****************************************
Report : check_design_states
Design : top
Version:
Date   : Thu Nov 28 02:17:49 2019
****************************************

Design is linked
```

Feedback

```
Design is 66.67% mapped
1
```

The check_design_states command displays the following information when option '-verbose' is specified.

```
prompt> check_design_states -verbose
****************************************
Report : check_design_states
Design : top
Version:
Date   : Thu Nov 28 02:23:40 2019
****************************************

Design is linked
Design is 66.67% mapped

Information: cell reg_p_i1/I_0 is unmapped. (NDMUI-915)
Information: cell I_0 is unmapped. (NDMUI-915)
1
```

---

check_duplicates

Checks, reports, and optionally removes any duplicate shapes and vias detected in the block.

Syntax

status *check_duplicates*

```
[-blocks block]
[-verbose]
[-remove]
[-object_types type_list]
[-return_as_collection]
```

Data Types

block	collection
type_list	list

Arguments

`-blocks {block}`

Specifies the block for finding duplicates. If this is not specified, duplicate objects are found in the current block. A summary of the total count of duplicate objects found are printed.

Feedback

`-verbose`

Generates informative messages. When you specify this option, the command writes all the duplicate objects in a text file duplicates.txt.gz in the current folder. This file contains the list of all duplicate objects found in the design. If there are no duplicates found, an empty file is be generated.

`-remove`

Reports and also removes all the duplicate objects found. It generates a text file duplicates.txt.gz in the current folder which contains detailed information about each of the duplicate objects deleted. A summary of the removed objects is printed in the log file. If there are no duplicates found, an empty file is generated.

`-object_types` *`type_list`*

Specifies the list of object types to be reported as duplicates. Valid values for this option are *shapes* and *vias*.

`-return_as_collection`

When you specify this option, this command returns duplicates in a collection. This option cannot be specified with *-remove* option.

Description

Checks, reports, and optionally removes all the duplicates found in the specified block. If no block is specified through the *-blocks* option, current block is used.

Two objects are considered to be duplicates if they are physically identical and are on the same net.

If *-verbose* option is not used, only a limited entries of duplicates are printed in the log file. A total of 20 rows and 5 duplicate objects in each row is printed by default. To get complete list of objects, use *-verbose* option. When this option is used, the complete list of objects is printed in the text file duplicates.txt.gz file in current folder.

If you specify the *-remove* option, reported duplicate objects are removed. In the log file, a summary of total objects removed are printed. A complete list of removed objects are printed in the text file duplicates.txt.gz file created in current folder.

Examples

The following example reports duplicate objects found in the current block.

```
prompt> check_duplicates

check_empty_space

Checks empty site in placeable region.

Syntax

status *check_empty_space*

```
[-include area]
[-exclude area]
[-1x_rule]
```

Data Types

```
area      collection
```

Arguments

`-include area`

Specifies empty site in the area should be reported. Area can be hard_keepout_margin, hard_keepout_margin_exclude_stdcell, hard_keepout_margin_of_stdcell, placement_blockage, preroute This argument cannot use -exclude simultaneous.

`-exclude area`

Specifies empty site in which should not be reported. Area can be hard_keepout_margin, hard_keepout_margin_exclude_stdcell, hard_keepout_margin_of_stdcell, placement_blockage, preroute This argument cannot use -exclude simultaneous. (You must specify one.)

`-1x_rule`

1x site with library missing 1x fill cell

Feedback

Description

Checks empty site in placeable region. You can define include or exclude area using application options.

Examples

The following example excludes hard_keepout_margin, hard_keepout_margin_exclude_stdcell, hard_keepout_margin_of_stdcell area and checks for empty space.

```
prompt> check_empty_space -exclude {hard_keepout_margin
 hard_keepout_margin_exclude_stdcell hard_keepout_margin_of_stdcell}
32
```

---

check_equivalent_power_domains

Check whether the power domains are equivalent and satisfy the criteria to share a single voltage area.

Syntax

status *check_equivalent_power_domains*

```
power_domains
[-functional_equivalence]
[-verbose]
```

Data Types

```
power_domains           list
```

Arguments

power_domains

Specifies the power domains to be checked. The command fails if the number of power domains are less than two.

-functional_equivalence

Specifies that domain supplies are considered as equivalent based on functional equivalence. If this options is not specified, by default, domain supplies are considered as equivalent based on electrical equivalence.

Feedback

`-verbose`

Shows the groups of equivalent power domains to share a primary voltage area.

Description

The *check_equivalent_power_domains* command checks whether the specified power domains are equivalent or not to share a voltage area. The command will return 1 if the specified power domains are equivalent and satisfy the criteria to share a primary voltage area, 0 otherwise.

This command supports the shared voltage area flow only with mv.upf.multi_pd_shared_voltage_area_flow set to new.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example compares two power domains that are not equivalent to share a voltage area.

```
prompt> check_equivalent_power_domains {pd1 pd2}
 0
```

The following example compares two power domains that are equivalent to share a voltage area.

```
prompt> check_equivalent_power_domains {pd3 pd4} -functional
 1
```

The following example compares power domains that are not equivalent to share a voltage area and shows the groups of distinct power domain subsets.

```
prompt> check_equivalent_power_domains {pd1 pd2 pd3 pd4} -verbose
Information: List of equivalent power domains - {pd1} {pd2} {pd3 pd4}.
 (UPF-483)
 0
```

See Also

Feedback

check_error

Returns true if message IDs specified in shell.common.check_error_list were encountered in previous commands.

Syntax

status *check_error*

```
[-verbose]
[-reset]
```

Arguments

`-verbose`

Displays the list of message IDs found during previous commands.

By default, the command only returns the error status.

`-reset`

Resets the list of previously found message IDs. After resetting the error list, the *check_error -verbose* command returns an empty list.

By default, the command does not modify the message list.

Description

The *check_error* command is used to compare error, warning, or informational messages issued by previous commands to the list of message IDs specified by *shell.common.check_error_list* application option. While it is most commonly used for error messages, the application option can contain error, warning, or informational message IDs.

If the *check_error* command finds message IDs that are specified in the *shell.common.check_error_list* application option, the command returns 1. If the *check_error* command does not find any messages that are specified by the *shell.common.check_error_list* application option, the command returns 0.

Messages that are suppressed by the *suppress_message* command are reported by *check_error*. If you want suppressed messages to be ignored by *check_error* then you must remove their message IDs from the *shell.common.check_error_list* application option.

Examples

The following example shows how to use the *check_error* command to check if execution errors are specified by the *shell.common.check_error_list* application option:

```
prompt> set_app_option -name shell.common.check_error_list -value
 {DES-001}
```

Feedback

```
prompt> check_error
0

prompt> get_cells
Error: Current block is not defined. (DES-001)

prompt> check_error
1

prompt> check_error -verbose
{DES-001}
1
```

The following command resets the error list:

```
prompt> check_error -reset -verbose
{DES-001}
1

prompt> check_error -verbose
0
```

To use the *check_error* command in a script to see if specified errors occurred in the previous commands, use the following command:

```
prompt> if { [check_error] } {
    echo failure_message
    exit
} else {
    echo success_message
}
```

See Also

- shell.common.check_error_list
- suppress_message

---

check_feedthroughs

Checks the feedthroughs on physical blocks.

Syntax

string *check_feedthroughs*

```
[-unused_feedthroughs]
[-reused_feedthroughs]
[-redundant]
[-net_constraints]
```

Feedback

```
[-topo_constraints]
[-include_original_feedthroughs]
[-include_buffered]
[-shape L | M | N]
[-pure]
[-self]
[-mixed]
[-close_to_edge]
[-tolerance_distance feedthrough_tolerance_distance]
[-filter_by_length]
[-feedthrough_length  feedthrough_length]
[-cells list_of_blocks]
[-alignment]
[-alignment_tolerance_distance distance_value]
```

Data Types

feedthrough_tolerance_distance	float
feedthrough_length	float
list_of_blocks	list
distance_value	float

Arguments

`-unused_feedthroughs`

Checks and reports feedthroughs pins that are not connected to a top-level net. Feedthroughs are not allowed in some designs. An example is a design with multiple instantiated blocks (MIB), where a feedthrough needs to be created on one MIB instance while it cannot be used by other MIB instances.

`-reused_feedthroughs`

Checks and reports feedthrough pins that are reused across multiple instantiated block (MIB) instances. This check only applies to MIB blocks.

`-redundant`

This option directs the command to look for redundant connections created on feedthrough nets. The pins it returns and reports are unnecessarily created either in the original netlist (if the *-include_original_feedthroughs* option is used) or by pin-placement during feedthrough creation. The option cannot be used with any other option except for the *-include_original_feedthroughs* option.

`-net_constraints`

Checks and reports feedthrough per-net, per-block feedthrough constraint violations. The command reports nets that violate feedthrough constraints and returns the associated feedthrough pins.

Feedback

`-topo_constraints`

Checks and reports nets that violate their associated topological constraints. The command reports nets that violate feedthrough constraints and returns the associated feedthrough pins where applicable.

`-include_original_feedthroughs`

Includes original feedthrough pins (not inserted by the tool) for checking. An original feedthrough is a feedthrough that exists in the original netlist. By default, original feedthrough pins are not checked.

`-include_buffered`

Skips over repeaters and buffers, when timing libraries are loaded, (effectively including buffered feedthroughs) when identifying, reporting, and checking feedthroughs.

`-shape L | M | N`

Reports feedthroughs of the specified shape. "L shaped" feedthroughs are two pin feedthroughs that have pins on adjacent edges. The *-tolerance_distance* option is used to specify how far these two feedthrough pins can be from the shared corner. "M shaped" feedthroughs have multiple-fanout pins. "N shaped" feedthroughs have feedthrough ports on the same edge. This option can only be used with the *-cells*, *-self*, or the *-tolerance_distance* options. The command also includes all feedthroughs for shape checking, including original feedthrough ports. However, "L" and "N" shape feedthrough reporting is limited to pure feedthroughs.

`-pure`

Reports and returns only the pure feedthroughs in the design. Pure feedthroughs are defined as feedthroughs that have no physical pins or connections (except for inverters/buffers) inside the block that they pass through. This option can only be used with the *-cells* or *-self* option.

`-self`

Reports and returns those ports and terminals of the top-level block that are feedthroughs. That is they are connected (potentially through multiple nets/hierarchies) to other top-level ports. This option can only be used with the *-include_original_feedthroughs*, *-include_buffered*, *-pure*, *-mixed*, *-shape*, *-close_to_edge*, and *-filter_by_length* options.

`-mixed`

Reports and returns only the mixed feedthroughs in the design. There are two types of mixed feedthroughs: 1. the feedthrough net has physical connections to combinational cell (besides inverters/buffers) inside the block that it passes

Feedback

through; 2. the feedthrough net owns both original and non-original feedthrough ports. This option can only be used with the *-cells* and *-self* options.

`-close_to_edge`

Checks for feedthrough ports that are within the specified distance from the same edge of the physical block. For a feedthrough port to be considered close to a given edge it should lie on a different edge and also on an edge that is of a different orientation than the edge it is close to. The check is limited to pure feedthroughs. The *-tolerance_distance* option can be used to specify the distance (in microns) from the edge. The default tolerance distance is 100 microns.

`-tolerance_distance` *`feedthrough_tolerance_distance`*

Specifies the tolerance distance that is used with the *-shape* and *-close_to_edge* options. When used with *-close_to_edge*, the feedthrough ports that are less than specified distance (in microns) from the same edge will be reported. When used with *-shape*, the distance applies to L-shaped feedthroughs only. The L-shaped feedthroughs that have both ports within specified distance from the same corner are reported. By default, the tolerance distance is 100 microns.

`-filter_by_length`

Checks for feedthroughs with nets whose length is less than the value specified by the *-feedthrough_length* option. Use this option to identify shorted feedthroughs. Note that the unplaced pins will be excluded in net length measurement.

`-feedthrough_length` *`feedthrough_length`*

Reports feedthroughs for nets with a length that is less than the specified *feedthrough_length* (in microns). The option can only be used with the *-filter_by_length* option and *-self* options. If routing is present for the net, the length of the route is used. Otherwise, half perimeter wire-length (from the bounding box of the net) is used to calculate the length. By default, the feedthrough length is 1000 microns.

`-cells` *`list_of_blocks`*

Specifies a list of blocks or cells for feedthrough checking.

`-alignment true | false`

Checks for intra block feedthrough alignment violations. The option is used to report unaligned IN & OUT feedthrough pins created on a block(intra block feedthrough).

The checking is limited to two-pin nets, and the two pins should be on parallel edges. Project the center points of the two pins onto the edge of either pin, compute the distance of two projected points, and compare the distance with the

Feedback

value specified by the *-alignment_tolerance_distance* option. If the former is no bigger than the latter, the two pins are thought as aligned.

The alignment may be vertical or horizontal.

`-alignment_tolerance_distance` *`distance_value`*

This option should be used with the *-alignment* option.

This option is to be specified in microns. If this option is specified, the value of the alignment tolerance distance is used to check intra block feedthrough alignment violations. By default, the alignment tolerance distance is 0 micron.

See the man page of the *-alignment* option for more details.

Description

This command is used to check and report feedthroughs issues, and returns a collection of feedthrough pins that correspond to the specified arguments/filters. If no option is specified, the command simply returns a collection of all the feedthrough pins. To include original feedthrough ports (not inserted by the tool) the *-include_original_feedthroughs* option can be used. To include buffered feedthrough nets for checking/reporting the *-include_buffered* option can be used.

By default the command looks for and checks feedthroughs at multiple levels of physical hierarchy (MPH support). The *set_editability* command can be used to enable or disable checking on individual reference-blocks or levels of physical hierarchy. For net constraint and topological checking a particular net is checked only if the instance in which it originates (its parent instance/hierarchy) is enabled for design planning.

Examples

The following example checks for unused feedthrough pins on all blocks.

```
prompt> check_feedthroughs -unused_feedthroughs
```

The following example checks for L-shaped feedthroughs on all blocks.

```
prompt> check_feedthroughs -shape L
```

The following command returns all tool inserted feedthrough ports

```
prompt> check_feedthroughs
```

The following command returns all feedthrough ports including the original feedthrough ports in the design.

```
prompt> check_feedthroughs -include_original_feedthroughs
```

---

check_finfet_grid

Checks for violations of object placement or boundary to the FinFET grid.

Syntax

status *check_finfet_grid*

```
[-objects object_name_or_collection]
[-hierarchical]
```

Data Types

```
object_name_or_collection    collection
```

Arguments

`-objects` *`object_name_or_collection`*

Specifies the objects to be checked. Currently supported object types are core_area, site_row, site_array, macro cell, I/O pad cell, flip chip river cell, and block cell. Other object types are not supported by this checker command. Specify the objects either by using an object access command, such as *get_site_rows*, or by specifying object name patterns in a Tcl list. By default, all supported objects in the current design are checked.

`-hierarchical`

Controls whether the objects within sub-blocks are checked. The *-hierarchical* option and *-objects* options are mutually exclusive. By default, the command only check objects in the current block.

Description

FinFET technology uses a grid which is about 40nm in pitch. The grid might have different pitch values in the x- and y-directions. Since FinFET is transistor in polysilicon layer, the boundary or placement of physical objects based on transistor should conform to FinFET grid. This command checks the physical design for violations against the FinFET grid. Standard cells must conform to FinFET grid. Since standard cells are placed in site rows, this command checks site rows rather than standard cells. If site rows are on FinFET grid, standard cells should be on FinFET grid automatically.

Feedback

If you receive error messages when you run this command, see the man pages for the error message IDs for information on how to fix the FinFET grid violations. After you fix the violations, run this command again to verify your fixes.

Examples

The following example shows the default command run.

```
prompt> check_finfet_grid
```

The following example shows command run on hierarchical design.

```
prompt> check_finfet_grid -hierarchical
```

The following example only checks hard macro cells.

```
prompt> check_finfet_grid -objects [get_cells -hierarchical -filter
 "design_type==macro"]
```

The following example only checks I/O pad cells.

```
prompt> check_finfet_grid -objects [get_cells -filter "design_type==pad"
 -hierarchical]
```

See Also

- get_cells
- get_site_rows

---

check_floorplan_rules

Reports violations of related floorplan spacing, enclosure, halo, length, area, width rules and track constraints.

Syntax

collection *check_floorplan_rules*

```
[list_of_rule_names]
[-object_types list_of_object_types]
[-lib_cells collection_of_lib_cells]
[-exclude_rules list_of_rule_names]
[-exclude_lib_cells collection_of_lib_cells]
[-objects macro_list]
[-bbox { {llx lly} {urx ury} }]
[-error_view view_name]
[-enable_rule_override true | false]
[-prf_object_types list_of_prf_object_types]
[-row_pattern row_pattern_name]
```

Feedback

Data Types

list_of_rule_names	list
list_of_object_types	list
collection_of_lib_cells	list
macro_list	list
llx	float
lly	float
urx	float
ury	float
view_name	string
list_of_prf_object_types	list
row_pattern_name	string

Arguments

list_of_rule_names

Specifies the list of floorplan rule names to report related violations. By default is checking all floorplan rules set by user.

-object_types *list_of_object_types*

Report floorplan rule violations on the listed object types. The object types include hard_macro, soft_macro, std_cell_area, boundary_cell_region, block_boundary, core_area, unplaceable_area, va_boundary, shape, cover_bump, io_pad, placement_blockage, routing_blockage, track, tsv. This option cannot be specified with the *-bbox* and *-objects* options.

-lib_cells *collection_of_lib_cells*

Report floorplan rule violations on the listed lib cells. This option cannot be specified with the *-bbox*, *-objects* and *-exclude_lib_cells* options.

-exclude_rules *list_of_rule_names*

Specifies the list of floorplan rules that will not report violations.

-exclude_lib_cells *collection_of_lib_cells*

Specified the lib cells that the violations will not be reported on them. If this option is specified with "-exclude_rules", only the violations match the "-exclude_lib_cells" and "-exclude_rules" will not be reported. This option cannot be specified with the *-bbox*, *-objects* and *-lib_cells* options.

-objects *macro_list*

Report floorplan rule violations on the listed macros. This option cannot be specified with the *-bbox*, *-object_types*, *-exclude_lib_cells* and *-lib_cells* options.

Feedback

`-bbox { {llx lly} {urx ury} }`

Report floorplan rule violations of macros that fully inside this region. This option cannot be specified with the *-objects*, *-object_types*, *-exclude_lib_cells* and *-lib_cells* options.

`-error_view view_name`

Specifies the name of the generated error view. If this options is specified, the command saves the error view data to a file in XML format with the specified name. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name. If this options is not specified, an attachment is created/modified and saved in to the design database with the file name as "#block_name#_floorplanRules.err" .

`-enable_rule_override true | false`

When set true, if a lib_cell has its own rule, the corresponding rules for hard_macro would not apply to instances of this lib_cell; In other words, one or more lib_cell rules to an object_type/lib_cell of a certain constraint type overrides any general rule to the same object_type/lib_cell of the same constraint type. Besides this, when it set true, cmd allow lib_cell-routing_blockage enclosure rule to override both hard_macro-routing_blockage enclosure rules and halo rules; Similarly, allow lib_cell-routing_blockage halo rule to override both hard_macro-routing_blockage enclosure rules and halo rules. The default value is false.

`-prf_object_types list_of_prf_object_types`

Specify the list of object types for checking based on Physical Rule, the value of prf_object_types can be site_row or track.

`-row_pattern row_pattern_name`

Specify the row_pattern name for which used for checking the site_rows/ wire_track based on specified PRF supported row_pattern definition.

Description

This command check floorplan rule violations set by the commands: *set_floorplan_spacing_rules set_floorplan_enclosure_rules set_floorplan_halo_rules set_floorplan_width_rules set_floorplan_area_rules set_track_constraint*

Examples

The following command checks floorplan rule_1 on hard and soft macros.

```
prompt> check_floorplan_rules rule_1 -object_types {hard_macro
 soft_macro}
```

Feedback

Assuming DTCD_lib is the ref lib of a DTCD cell and DTCD cell has the design type of hard macro, the following command reports all macro cell violations except for DTCD cells.

```
prompt> set_floorplan_spacing_rules -name R1 \\
   -from_lib_cells DTCD_lib -to_object_types std_cell_area

prompt> set_floorplan_spacing_rules -name R2 \\
   -from_object_types hard_macro -to_object_types std_cell_area

prompt> check_floorplan_rules R2 -enable_rule_override
```

- set_track_constraint

---

check_freeze_silicon

Performs feasibility analysis on ECO-cell-to-spare-cell mapping for the current design. This command is typically used in a freeze silicon ECO flow.

Syntax

status *check_freeze_silicon*

Data Types

This command has no data types.

Arguments

This command has no arguments.

Feedback

Description

The *check_freeze_silicon* command performs feasibility analysis on ECO-cell- to-spare-cell mapping for the current design. The report includes feasibility analysis on ECO cell to spare cell mapping and ECO cell to programmable spare cell (PSC) mapping.

For ECO cells without a PSC type, the report includes:

- The total number of ECO cells and spare cells in the design
- ECO cell mapping feasibility analysis
- Detailed information about the number of ECO cells and spare cells for each library cell

For ECO cells with a PSC type, the report includes:

- The total number of ECO cells and PSC on the design
- ECO cell mapping feasibility analysis for each voltage area and PSC type group
- ECO cells vs. PSC detail report
- Abutted PSC width detail report

When a PSC mapping rule is defined, the "Derived PSC Type", "Derived PSC Width" and "Total PSC Width" columns are shown in the mapping analysis report. The report only includes valid programmable spare cells, while the invalid programmable spare cells due to the PG overlap rule violation are skipped a and the ECO-079 and ECO-090 warning messages are issued.

The command reports feasibility analysis results on ECO cells without a PSC type, then reports ECO cells with a PSC type. The two sections are separated by a section header.

It is recommended that the command is used before the *place_freeze_silicon* command to help you analyze ECO cells and spare cells in your design and to be aware of potential spare cell mapping failures.

The command behavior is the same regardless of the *design.eco_freeze_silicon_mode* application option setting.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example shows a feasibility check report.

```
prompt> check_freeze_silicon
  ...
```

Feedback

```

check_frontside_fibs

Checks FIB module logical and physical correctness, and coverage requirements.

Syntax

status *check_frontside_fibs*

Feedback

```
[-bbox bounding_box]
[-percent_goal percent_goal]
[-prefix name_prefix]
[-max_route_layer layer_name]
```

Data Types

```
bounding_box      list
percent_goal      float
name_prefix       string
layer_name        string
```

Arguments

`-bbox bounding_box`

Specifies the area in which check needs to be performed.

```
{{llx lly} {urx ury}}
```

`-percent_goal percent_goal`

Specifies the expected coverage.

`-prefix name_prefix`

Specifies the prefix to identify fib cells. Default is "fib_logic_".

`-max_route_layer layer_name`

Specifies the maximum routing layer. If this value is less than top routing layer, it will assume this is a sub-block.

Description

This command scans the area indicated by *-bbox. If not specified, entire core area is scanned.*

Starting from the lower left corner of -bbox or core area, the check area is divided into windows. Scan window size is set by app option eco.post_silicon_debug.fs_fib_check_window_size. Default is 50um. The command will check number of windows with nand, nor, inv, and buffer type fib cells and report coverage percentage for each type of fib cells.

It will also report if tie cells missing or not routed in the top 2 routing layers. It also checks if there are any short/open fib nets.

Examples

```
prompt> check_frontside_fibs -percent_goal 25 \\
    -bbox {{10 50} {50 85}} \\
    -prefix "pe_" -max_route_layer M5
```

create_frontside_fibs(2)

check_hier_design

Checks a hierarchical design for possible issues related to top-level closure. This command can be configured to report, tolerate or repair the errors. Messages generated by this command are captured in an EMS database file and in the log file.

Syntax

status *check_hier_design*

```
[-stage timing | pre_placement | pre_clock_tree | pre_route | pre_compile
 | pre_compile_tho | pre_route_tho]
[-references   reference_design_names]
```

Data Types

reference_design_names list

Arguments

`-stage timing | pre_placement | pre_clock_tree | pre_route | pre_compile`

Performs atomic checks for the specified design stage.

-stage timing performs timing-related checks.

-stage pre_placement performs both timing and pre-placement related checks.

-stage pre_clock_tree performs timing, pre-placement, and pre-clock-tree checks.

-stage pre_route performs pre-route checks.

-stage pre_compile performs checks to ensure that blocks linked to top are ready for compile.

-stage pre_compile_tho performs both pre-placement and THO related checks.

-stage pre_route_tho performs both pre-route and THO related checks.

By default, only timing checks are run if this option is not specified.

`-references` *reference_design_names*

Specifies the names of design references, for physical hierarchies in the top-level design, on which to run checks. By default, all physical hierarchies are checked if this option isn't specified.

Feedback

Description

This command performs design checks for use in the top-level closure flow. The checks that report error can be alternatively configured to issue warning or repair the underlying issue.

check_hier_design command honors the error, tolerate and repair policy settings of hierarchical checks configured using *set_early_data_check_policy* command. The policies can be configured for each hierarchical check for each physical hierarchy reference.

- error - When the check fails, command issues error. This is the default behavior of the command.
- tolerate - When the check fails, command issues warning.
- repair - When the check fails, command performs repair work to resolve the error condition and issues information on successful repair and error message in case of repair failure.

The repairs performed are saved to the block within the check_hier_design command. To ensure that the repair work gets saved to the sub-block, following are required:

- Editability should be enabled on the sub-blocks on which repair has to be performed.
- Ref-libs containing the sub-blocks should be opened for edit.

Repairs will be allowed to happen only if the bound view is read only abstract view or editable design view.

When the repairs are performed, the records of the repair shall be created. The records of the repair shall be saved when the repair gets saved to the design. Use *get_early_data_check_records* to get a collection of the records. Use *report_early_data_checks -verbose -hierarchical*, to get the exact detail on the repair done.

The command writes the Error, Warning and Information messages to Enhanced Messaging System(EMS) database file and into text log file.

If THO related stages *pre_compile_tho and pre_route_tho* are used before init_hier_optimization, tool will internally promote dont_touch/size_only constraints from editable sub-blocks to top-level so that these constraint statistics are appropriately reported.

Examples

The following example performs timing-related checks.

```
prompt> check_hier_design -stage timing
```

The following example performs pre-placement checks on the RISC_CORE block.

Feedback

```
prompt> check_hier_design -stage pre_placement -references RISC_CORE
```

The following example performs timing-related checks and writes the results to the EMS database named check_hier.ems

```
prompt> create_ems_database check_hier.ems
prompt> check_hier_design -stage timing
prompt> save_ems_database -all
```

The following example sets repair policy on hier.block.missing_frame_view check.

```
prompt> open_block -ref_libs_for_edit ORCA.nlib:ORCA.design
prompt> set_early_data_check_policy -policy repair -check
 hier.block.missing_frame_view -references RISC_CORE
prompt> set_editability -blocks RISC_CORE -value true
prompt> check_hier_design -stage pre_placement -references RISC_CORE
```

The following example performs THO related checks.

```
prompt> check_hier_design -stage pre_compile_tho
prompt> check_hier_design -stage pre_route_tho
```

- commit_hier_optimization

---

check_host_options

Checks that the specified host option is working properly in your environment.

Syntax

```
status check_host_options
-host_options  host_option_name
-target        target_value
[-work_dir     directory]
[-timeout      timeout_value]
```

Feedback

Data Types

```
host_option_name    string
target_value        string
directory           string
timeout_value       int
```

Arguments

`-host_options` *host_option_name*

Specifies the name of the host option to be checked. Host options are created using the *set_host_options* command. This is a required option.

`-target` *target_value*

Specifies the name of the target application.

`-work_dir` *directory*

Specifies a working directory where various data and log files will be written. By default, the directory is ./work_dir. This directory must be a network disk accessible by all workers.

`-timeout` *timeout_value*

Specifies the maximum time to run the command. Value should be greater than or equal to 0.

Description

This command tests the specified distributed processing host option to ensure that the host option is correctly specified for your environment. The command launches a worker process using the host options. This worker process only informs the master process that it is alive and exits.

You should use this command to test your host option settings before beginning a distributed processing run. If this command does not complete successfully, do not use the given host option with any other command because it will not work. Instead, determine the reason for the failure and fix the given host option, or run without distributed processing.

If you have problems getting this command to complete successfully, try first using a simpler host option. You can also try using rsh rather than LSF or GRD.

Examples

This simple example sets the host option named myLSFtest for LSF distributed processing, then checks the setting.

```
prompt> set_host_options -name myLSFtest -submit_command "bsub"
1
prompt> check_host_options -host_options myLSFtest
```

Feedback

```
Checking host option: myLSFtest
check_host_options successful.
```

See Also

- set_host_options

---

check_io_placement

Performs I/O placement checking.

Syntax

list *check_io_placement*

```
[-cells cell_collection]
[-matching_types matching_type_collection]
[-io_guides io_guide_collection]
[-pad_assignment_file file]
[-filename filename]
[-output_directory directory]
[-error_view view_name]
[-overlap all | pad2pad | pad2filler | filler2filler | bump | corner2pad]
[-bump_assignment]
[-pad_to_guide_assignment]
[-signal_constraints]
[-power_constraints]
[-unplaced]
[-flipping]
[-gap]
[-min_pitch]
```

Data Types

cell_collection	list
matching_type_collection	list
io_guide_collection	list
file	string
filename	string
directory	string
view_name	string

Arguments

`-cells` *cell_collection*

Specifies cell instances, such as bumps, pads, fillers, for I/O placement checking. If this option is used, only the specified cells are checked. If this option is used but the specified cells are not valid objects for some specified checks, the specified cells are ignored for those checks. Option *-cells* cannot be used

Feedback

together with option *-signal_constraints*, *-power_constraints*, *-min_pitch*, and *-gap*.

`-matching_types` *`matching_type_collection`*

Specifies user-defined matching types for I/O placement checking. If this option is used, only the specified matching types are checked. If this option is used and the specified matching types are not valid objects for the specified checks, this specified matching types are ignored for those checks. Option *-matching_types* cannot be used together with option *-pad_to_guide_assignment*, *-signal_constraints*, *-power_constraints*, *unplaced*, *-min_pitch*, *-gap* and *-flipping*.

`-io_guides` *`io_guide_collection`*

Specifies the I/O guides for I/O placement checking. If this option is used, only the specified I/O guides are checked. If this option is used and the specified guides are not valid objects for the specified checks, this specified matching types are ignored for those checks. Option *-io_guides* cannot be used together with option *-bump_assignment*, *unplaced* and *-flipping*.

`-pad_assignment_file` *`file`*

Specifies the file which contains a list of I/O pad cells and corresponding I/O guides that are allowed for the I/O pad. Entries in this file specify a constraint that limits the pad placement to only the listed I/O guide candidates. If the file is not specified or file cannot be opened, the limitations in file will not be checked. This option can only be used with option *-pad_to_guide_assignment*.

The pad assignment file lists the constraints for the specified I/O pads. Each line contains one or more pad names followed by a list of allowed I/O guide names. I/O guides not in the list cannot be used to place the pads. If more than one pad is listed on one line, the pads must be placed within a pair of curly braces. No curly braces are needed for I/O guides. Each line must end with a semicolon.

```
{pad1 pad2} guide1 guide2;
pad3 guide1 guide3 guide0;
```

`-filename` *`filename`*

Specifies the name of the file where the reports of I/O placement checking are written. Only 10 lines are printed to prompt for each report. In the file, the complete reports are shown. The option cannot be used together with *-output_directory* option.

`-output_directory` *`directory`*

Writes individual report files for each check (overlap, bump assignment, and so on) to the specified directory. The report file names are the name of the check. If the directory does not already exist, the command tries to create the directory.

Feedback

If creation is successful and write permissions are appropriate, the output is written to individual files created in this directory instead of the console. The option cannot be used together with the *-filename* option.

`-error_view` *`view_name`*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file.

If this option is omitted, the error view data is stored as an attachment to the design database. When the design is closed and saved, the error view data is saved to the design database as well. The saved error view data does not change until the next *check_io_placement* command.

`-overlap all | pad2pad | pad2filler | filler2filler | bump | corner2pad`

Checks different kinds of overlaps, including pad-pad overlap, pad-filler overlap, filler-filler overlap, bump overlap and corner-pad overlap. One or multiple valid strings must be provided to enable corresponding checks. The valid strings are all, pad2pad, pad2filler, filler2filler, bump. If "all" is specified, the other string is ignored and all kinds of overlap are checked.

If a certain type of overlap checking is specified and invalid objects are specified, only the valid objects are checked and the invalid objects are ignored. For example, if bump overlap checking is specified and some bumps cells and filler cells are specified, the filler cells are ignored.

`-bump_assignment`

Checks if bump assignment after place_io is consistent with defined matching types (if any) and logical nets. This option works alone or together with *-cells* and *-matching_types*. If the option is specified by itself, all bumps are checked for correct bump assignment. If the other type of objects are specified, they are ignored for this checking.

`-pad_to_guide_assignment`

Checks if current pad-to-guide assignment is consistent with the definition. If the option is specified by itself, all pads are checked for placement on the correct guides. Use the *-cells* option to specify the pads to check. If *-io_guides* is specified, all pads that should be placed on specify I/O guides are checked. To use together with *-pad_assignment_file* option, a pad assignment file must be provided. All the pads mentioned in the file are checked. The other type of objects are ignored for this checking.

Feedback

`-signal_constraints`

Checks if there are signal I/O pads violating constraints set by *set_signal_io_constraints*. Signal I/O constraints include order, pitch, spacing, offset of pads and boundary-spacing. If the option is specified by itself, all I/O guides with signal I/O constraints are checked.

Note that option *-cells* cannot be used with *-signal_constraints*, as signal I/O constraints can only be set with guides. And in some cases, such as specifying one cell to check for signal pads order, it does not make sense.

`-power_constraints`

Checks if there are power pads violating constraints set by *set_power_io_constraints*. Power I/O constraints include share, ratio, spacing and offset.

Note that option *-cells* cannot be used with *-power_constraints*, as power I/O constraints can only be set with guides. And in some cases, such as specifying one cell to check for power pads ratio, it does not make sense.

`-unplaced`

Checks if there are any unplaced pads. If this option is specified by itself, all pads are checked if it is unplaced. If other types of cells are specified, such as fillers, those cells are still checked but with a warning indicating those cells are not pads. If no cells are specified, by default only all pads are checked.

`-flipping`

Checks if the I/O pads are consistent with the is_flipped attribute as set in the design. If a pad is not placed on any guide, the pad is also considered to violate placement.

`-gap`

Checks if there is a gap between any two adjacent cells on I/O guides. The unfilled space that is outside the length of the I/O guides are not considered as gap. The valid cell types include pads, corners, fillers and break cells.

`-min_pitch`

Checks if the min_pitch set with I/O guides are honored by place_io.

Description

This command performs one or multiple kinds of I/O placement checks and return a collection of cells with violations. All options are optional. If no option is used, the command runs all checks. As each checking has different valid objects and options to work with, each check finds the valid objects for the check within the specified objects. Each check ignores the options that specify invalid objects. If the objects specified by an option is not valid for any checking, a warning is issued to indicate the option is not used.

Feedback

By default, the reports of checks are printed to the console. Each check is written out in a section in report and each section can shows 10 lines of violations at most. You can choose to write out the complete report to files or a directory with options.

Examples

The following example checks bump assignment for all bumps and signal I/O constraints for specified guides.

```
prompt> check_io_placement -bump_assignment -signal_constraints
 -io_guides [get_io_guides *]
```

- set_signal_io_constraints

---

check_isolation_coverage

Reports isolation violations, that are not handled between power domain boundaries in a UPF design.

Syntax

status *check_isolation_coverage*

```
-dft_signals
[-from power_domain_name_list]
[-to power_domain_name_list]
[-clamp_value clamp_value_list]
[-ignore_unimplemented_strategies]
[-suggest_domain_based]
```

Data Types

```
power_domain_name_list  list
clamp_value_list        list
```

Arguments

`-dft_signals`

Restrict the report to only check logic signal paths involving DFT signal pins.

Feedback

The following are the supported DFT signal types: scan_clock, scan_in, scan_out, scan_in_out, scan_enable, test_mode, input_wrp_shift, output_wrp_shift, wrp_shift, wrp_clock, wrp_ded_capture_in, wrp_ded_capture_out, wrp_ded_capture_inout, wrp_td_test, wrp_safe_in, wrp_safe_out, pse_clock, los_pipeline_enable, test_point_clock, test_point_test_mode.

`-from` *`power_domain_name_list`*

Restrict the report to only show isolation violations where the driver is located in one of the power domains named in *power_domain_name_list*. All domain names included in *power_domain_name_list* are required to references an existing power domain in the design.

`-to` *`power_domain_name_list`*

Restrict the report to only show isolation violations where the sink is located in one of the power domains named in *power_domain_name_list*. All domain names included in *power_domain_name_list* are required to references an existing power domain in the design.

`-clamp_value` *`clamp_value_list`*

Restrict the report to only show applicable isolation strategies that match the one the clamp values listed in *clamp_value_list*. Values allowed for *clamp_value_list* are: 1, 0, latch, all. A value "all" is equivalent to {1, 0, latch} and is the default assumed if *-clamp_value* is not used.

`-ignore_unimplemented_strategies`

This option causes the tool to ignore unimplemented isolation strategies when evaluating if a signal path has an isolation violation.

`-suggest_domain_based`

set_dft_isolation strategy suggestions use -dft_target_domain/-dft_source_domain instead of -dft_sink_supply/-dft_source_supply

Description

The *check_isolation_coverage* command reports logic signal paths containing isolation violations that are not handled, that is, signal paths that:

\- Contain at least one power domain boundary crossing between the driver and the load

where the violation is found."

Feedback

\- No isolation strategy is found to be defined (either implemented or yet to be implemented)

on any of the domain boundaries in between the driver and load. Note that a signal path with an applied isolation strategy whose isolation supply cannot drive its loads, is still considered as "covered" by said isolation strategy.

The report consists of several section tables, each one corresponding to a 'driver power domain' and "load power domain" pair containing:

\- Driver power domain info

Information about the 'driver power domain', including: domain name, primary supplies and available secondary supplies.

\- Load power domain info

Information about the 'load power domain', including: domain name, primary supplies and available secondary supplies.

\- Violating paths info

Information about the logic signal paths found to contain an isolation violation that is not handled, between its driver and its loads. The driver is expected to reside inside the 'driver power domain' and its loads are expected to reside inside the 'load power domain'

\- Applicable isolation strategies from the 'driver power domain'.

Details of existing isolation strategies in the 'driver power domain' found to be usable to address some of the isolation violations found on the reported signal paths.

\- Applicable isolation strategies from the 'load power domain'.

Details of existing isolation strategies in the 'load power domain' found to be usable to address some of the isolation violations found on the reported signal paths.

By default, section tables for all 'driver power domain' to 'load power domain' pairs where isolation violations that are not handled are detected and included in the report. You can make use of the *-from* and *-to* options to control which section tables are shown.

Examples

The following command generates a report that includes all signal paths with an isolation violation not covered by an existing isolation strategy.

```
prompt> check_isolation_coverage -dft_signals
```

Feedback

The following command filters out any violating signal path whose global driver is not located on either power domain PD1 or PD2.

```
prompt> check_isolation_coverage -dft_signals -from {PD1 PD2}
```

The report generated by this command only shows available isolation strategies with a clamp value of 0.

```
prompt> check_isolation_coverage -dft_signals -clamp_value {0}
```

See Also

- commit_dft_isolation
- set_dft_isolation
- set_isolation

---

check_legality

Checks the legality of the current placement.

Syntax

status *check_legality*

```
[-verbose]
[-cells list_of_cells]
[-chipfinishing auto]
[-check_distance distance]
[-cell_violation]
[-info_violation]
[-max_info number]
[-output_tcl]
```

Data Types

```
list_of_cells  collection
mode           string
distance       float
number         integer
```

Arguments

`-verbose`

Prints a detailed report of all possible violations. By default, the command reports only a summary of all violations.

`-cells list_of_cells`

Specifies the cells to check.

Feedback

When you use this option, the *check_legality* command performs legality check only on the specified cells and cells within the checking distance, which reduces runtime.

By default, the checking distance is three row heights. To adjust the checking distance, use the *-check_distance* option.

`-chipfinishing` *`auto`*

Specifies the chipfinishing mode to check.

When you use the option, the *check_legality* command performs legality check for chipfinish stage. (advanced legalizer only)

The *chipfinishing auto* checks basic rules such as *overlap*, *cell_on_site*, and *legal_orient*, and AL rules such as *spacing_rule*, and chipfinishing rules such as *tap_coverage*, *continuity* and so on.

`-check_distance` *`distance`*

Specifies the checking distance in number row heights. The specified distance must be a float value greater than or equal to zero.

The checking distance determines the neighboring cells to include in legality checking when you use the *-cells* option.

By default, the distance is three row heights.

This option can be used only with the *-cells* option.

`-cell_violation`

The command will return all violated cells as a collection. You can assign the return value of the check_legality command to a TCL variable to process the collection of violated cells.

`-info_violation`

The command will return a TCL list of all violations. You can assign the return value of the check_legality command to a TCL variable. The option *-max_info* can be used to limit the number of returned violations.

`-max_info` *`number`*

Limits the number of returned violations from option *-info_violation*.

`-output_tcl`

Writes a Tcl file that contains all illegal cells with different violation types. The current process ID (pid) is appended to the file name so the tool can determine if the Tcl file was created in this session.

Feedback

This option applies only to the classic legalizer. When the advanced legalizer is enabled (the *place.legalize.enable_advanced_legalizer* application option is *true*), the command does not write a Tcl file. Instead, the command writes an error file that you can view in the GUI error browser.

By default, no Tcl file is generated.

If you are using the classic legalizer and you use this option, by default, the generated Tcl file contains all moveable cells with violations. You can change this by modifying two variables in the Tcl file, GLOBAL_VIOLATION_TYPE and GLOBAL_VIOLATION_MODE. For information about the valid values for these variables, see the header section at the beginning of the Tcl file.

You can use the generated Tcl file for different purposes, such as

- Fixing violations based on a specific violation type rather than all violation types. For example, use this file to select only overlapped cells and leave other violations as-is.
- Highlighting all violated cells or specific types of violations and avoid parsing the output of the *check_legality -verbose* command.
- Selecting violated cells based on moveable, application fixed, or fixed type. For example, you can select only CTS spacing violations marked as application fixed.
- Using the script information with your own scripts after the collection is created. The generated collection can be used with your own scripts.

Description

The *check_legality* command checks the legality of the current placement and output a report of violation statistics.

By default, the command runs the classic legalizer. To run the advanced legalizer, set the *place.legalize.enable_advanced_legalizer* application option to *true*.

The reported violations can be classified as

- Cells that are not on rows
- Cells overlapping each other
- Cells overlapping blockages
- Cells with orientation that is not allowed for the row on which the cell is placed
- Cells with a core site type not equal to that of the row on which the cell is placed
- Cells with power strap violations

Feedback

- Cells with advanced technology (20 nm and below) violations
- Cells with placement spacing rule violations

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks the legality of all cells and prints a summary of all violations.

```
prompt> check_legality
```

The following example checks all BUF* cells in the design.

```
prompt> check_legality -cells [get_cells BUF*]
```

The following example checks cells in the my_cell_list collection.

```
prompt> check_legality -cells $my_cell_list
```

The following example checks cells added in the my_cell_list collection and cells within 5.5 row heights.

```
prompt> check_legality -cells $my_cell_list -check_distance 5.5
```

The following example checks all BUF* cells in the design using the default three row height checking distance and writes out a Tcl file including all violated cells.

```
prompt> check_legality -cells [get_cells BUF*] -output_tcl
```

The following example checks chipfinishing related rules.

```
prompt> check_legality -chipfinishing auto
```

The following example returns a collection of violated cells.

```
prompt> set violated_cells [check_legality -cell_violation]
```

- create_placement
- legalize_placement
- place.legalize.enable_advanced_legalizer

---

check_legalizer_sanity

Does a series of sanity checks on the design to handle dirty data input.

Feedback

Syntax

status *check_legalizer_sanity*

Description

The *check_legalizer_sanity* command performs a series of sanity checks on the current design (eg. - testing the library, user input design constraints) to avoid legalizer issues.

Running this command before running legalize_placement helps user identify dirty (bad design) inputs that might cause issues like long runtime or hang later, beforehand. The output generated is in the form of Error/Warning messages.

This command helps the user to save time by debugging the cause before legalization runs into problems at later stages; and decide how to proceed.

Examples

The following example runs the *check_legalizer_sanity* command:

```
prompt> check_legalizer_sanity
```

See Also

- check_legality

---

check_libcell_pin_access

Check pin accessibility between abutted standard cells for the reference libraries of current library.

Syntax

```
status check_libcell_pin_access
-mode analyze_lib_cell | analyze_lib_pin | single_cell |
 single_cell_vertical | cell_by_cell | design_under_test |
 congested_random_placement | composite_cell
[-from prepare | place | report_place | route | report_route]
[-to prepare | place | report_place | route | report_route]
```

Arguments

```
-mode analyze_lib_cell | analyze_lib_pin | single_celll |
single_cell_vertical | cell_by_cell | design_under_test |
congested_random_placement | composite_cell
```

Specifies the checking mode with different analyzing methods or different cell combinations.

This is a required argument.

Feedback

- *analyze_lib_cell*:

  Creates a fake design with all or the specified library cells and runs *analyze_lib_cell_placement* command, which tests a collection of library cells for their ability to be placed in the current floorplan. It reports a pass rate for each library cell tested.

  No cell placement and routing is performed in this mode. Uses this mode to detect problematic cells before legalization and to avoid long runtime or hang issue in early stage due to certain cells are hard to find a legal location.

- *analyze_lib_pin*:

  Creates a fake design with all or the specified library cells, legalize them, and then runs *report_cell_pin_access* command, which reports number of access points for pins of each library cell. The report will reflect current settings for the *place.legalize.advanced_layer_access_check* application option.

  In the end of run, the tool generates a report file called risky_pin_access_[pin_extMode].rpt and prints script in the report to list the cells with potential pin access issue. The extension mode can be set by the *pin_check.analyze.report_cell_pin_access_mode* application option.

- *single_cell*:

  Performs fast checking on the target cell to against the cell itself and ensures there is no pin accessibility issue within a cell itself. The target cells can be set by the *pin_check.input.cells* application option.

  A separate block is generated for each target cell, named single_cell/cell_[refCellName].design. This mode considers horizontal cell abutment, here is an example of target cell A to against itself.

  ```
  +---+---+---+  +---+---+---+
   | A | A | A |   | A | A | A |
   +---+---+---+  +---+---+---+
  ```

- *single_cell_vertical*:

  Performs fast checking on the target cell to against the cell itself and ensures there is no pin accessibility issue within a cell itself. The target cells can be set by the *pin_check.input.cells* application option.

  A separate block is generated for each target cell, named single_cell_vertical/cell_[refCellName].design. This mode considers vertical cell abutment, here is an example of target cell A to against itself.

  ```
  +---+
   | A |
   +---+
  ```

Feedback

```
| A |
+---+
| A |
+---+

+---+
| A |
+---+
| A |
+---+
| A |
+---+
```

- *cell_by_cell*:

  Checks the target cell to against other cells in the reference libraries. This mode is easy to isolate one cell against all the other cells at a time. The against cells can be set by the *pin_check.input.include_for_checking* application option.

  A separate block is generated for each target cell, named cell_by_cell/cell_[refCellName].design. The horizontal cell abutment for target cell A to against cell B, C ... is like below.

```
+---+---+---+  +---+---+---+   +-----+---+-----+
 +-----+---+-----+
 | B | A | B |  | B | A | B |   |  C  | A |  C  |  |  C  | A |
  C  |  ...
 +---+---+---+  +---+---+---+   +-----+---+-----+
 +-----+---+-----+
```

  Cells that are checked against the target cell can be filtered by pin count. The control is by the *pin_check.input.filter_cells_by_pin_count* application option.

  Or cells can be enumerated and instantiated in multiples per target cell. (The control is only for congested_random_placement mode.) The control is by the *pin_check.input.checking_multiplier* application option.

  Here is an example with checking_multiplier 2.

```
+---+---+---+  +---+---+---+
 | B | A | B |  | B | A | B |
 +---+---+---+  +---+---+---+    ...
 | B |   | B |  | B |   | B |
 +---+   +---+  +---+   +---+
```

Feedback

- *design_under_test*:

  Surrounds the target cell by other cells, which are placed with minimum placement spacing rules. This mode considers both horizontal and vertical cell abutment.

  A separate block is generated for each target cell, named design_under_test/cell_[refCellName].design. The cell abutment for target cell A to against cell B, ... is like below.

```
+---+---+---+
 | B | B | B |
 +---+---+---+
 | B | A | B |    ...
 +---+---+---+
 | B | B | B |
 +---+---+---+
```

  User can create multiple copies of the DUT cell by the *pin_check.place.design_under_test_multiplier* application option. Here is an example with design_under_test_multiplier 2.

```
+---+---+---+---+
 | B | B | B | B |
 +---+---+---+---+
 | B | A | A | B |    ...
 +---+---+---+---+
 | B | B | B | B |
 +---+---+---+---+
```

- *congested_random_placement*:

  Provides additional routing and horizontal/vertical adjacent cells into the test design. User can set the connectivity across cells from all directions by the *pin_check.common.random_netlist* application option.

  A separate block is generated for each target cell, named congested_random_placement/cell_[refCellName].design. The target cells A are spreaded in the design as below, and the other checking cells are randomly added surrounding A in the design.

```
A    A    A

     A    A    A    A    A

     A    A    A    A    A

     A    A    A    A    A

          A    A    A
```

Feedback

- *composite_cell*:

  Provides composite cells into the test design for analysis. User can specifies number of cells by instance count or cell ratio and control the routing complex by the pin distance and fanout factor to simulate the real case. These are the application options provided for this mode:

  ```
  pin_check.analyze.composite_cells
    pin_check.analyze.composite_inst_count
    pin_check.analyze.composite_cell_ratio
    pin_check.analyze.composite_core_width
    pin_check.analyze.composite_core_height
    pin_check.analyze.composite_pin_dist
    pin_check.analyze.composite_fanout_num
  ```

  After checking, the command reports the cell instance count and DRC for each library cell. It provides a score to predict cell routability based on the equation, score = [1 - (DRC count / Instance count)] * 100 The DRC issue cells in the report will be reviewed by user.

`-from prepare | place | report_place | route | report_route`

Specifies the starting step for pin accessibility checking. The default value is "prepare".

For a new design library, user can only start from "prepare" step.

For an existing design library, user can start from next step of current state.

```
- If the test design is prepared already, user can start from
 "place".
- If the test design is placed already, user can start from
 "report_place" or "route".
- If the test design is routed already, user can start from
 "report_route".
```

User can also start from the step ahead the existing state to overwrite current result.

The option is ignored when *-mode* is analyze_lib_cell or analyze_lib_pin.

`-to prepare | place | report_place | route | report_route`

Specifies the ending step for pin accessibility checking. The default value is "report_route".

User can stop at any step behind the *-from* step.

```
- When the command is ending at "prepare", the test design is
 prepared and saved.
- When the command is ending at "place" or "report_place", the
 test design is placed and saved.
```

Feedback

```
   - When the command is ending at "route" or "report_route", the
    test design is routed and saved.
```

The option is ignored when *-mode* is analyze_lib_cell or analyze_lib_pin.

Description

The *check_libcell_pin_access* command checks the reference libraries pin accessibility between abutted standard cells.

The recommanded flow for the pin accessibility checking is as below.

```
(1) Baseline cell analysis.

    # Analyzes the library cells for the ability to be placed.
    check_libcell_pin_access -mode analyze_lib_cell

    # Analyzes the routability by pin access check and finds the risky
 cells.
    check_libcell_pin_access -mode analyze_lib_pin

(2) Baseline checks for risky cells.

    set_app_options -as_user_default -name pin_check.input.cells -value
 $riskyCells

    # simple check
    check_libcell_pin_access -mode single_cell

    # check against all other cells
    check_libcell_pin_access -mode cell_by_cell

(3) Multidimensional checks.

    check_lib_cell_pin_access -mode design_under_test
    check_lib_cell_pin_access -mode congested_random_placement
```

The command has five steps in the full checking process.

```
- "prepare": Creates test design for each target cell and generates cell
 combination and netlist.
  - "place": Initializes the floorplan and performs cell placement and
 legalization.
  - "report_place": Performs check_legality and reports the ligalization
 errors.
  - "route": Performs routing commands, such as route_auto, route_detail
 or route_eco.
  - "report_route": Performs check_routes and reports the routing DRC.
```

The command uses the *pin_check.** application options to control the whole checking flow, including six categories.

Feedback

```
pin_check.input.*: setting for target cells, excluding cells, against
 cells, cell filter
  pin_check.common.*: general setting such as tech_node, netlist,
 parallel control, PG routing, ...
  pin_check.analyze.*: setting for -mode analyze_lib_cell,
 analyze_lib_pin and composite_cell
  pin_check.place.*: setting for placement and legalization
  pin_check.route.*: setting for routing
  pin_check.report.*: setting for signoff_check_drc and derive cell
 spacing constraints
```

The command supports GRD-based parallel P&R.

```
set_app_options -as_user_default -name pin_check.common.grd -value true
  set_app_options -as_user_default -name pin_check.common.grd_command
 -value $grdCmd

  set_app_options -as_user_default -name
 pin_check.common.num_cells_per_run -value 20
  or
  set_app_options -as_user_default -name pin_check.common.num_jobs -value
 10
```

The command supports PG routing before or after placement, or user can specify the PG script file.

```
set_app_options -as_user_default -name pin_check.common.route_pg -value
 before_placement
  set_app_options -as_user_default -name pin_check.common.pg_script_file
 -value $pgFile
```

Limitations

Current library must exist and which is created by command *create_pin_check_lib*.

Examples

Example 1) Run pin accessibility checking in one run for all library cells. The preplaced option file is required for placement.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.place.preplace_option_file -value
 preplace_options.tcl
prompt> create_pin_check_lib myTestLib -technology a.tf -ref_libs STD
prompt> check_libcell_pin_access -mode cell_by_cell
```

Example 2) Run pin accessibility checking in multiple jobs. Each job runs 5 cells in placing and routing.

```
prompt> set_app_options -as_user_default -name
 pin_check.common.num_cells_per_run -value 5
prompt> set_app_options -as_user_default \\
```

Feedback

```
        -name pin_check.place.preplace_option_file -value
 preplace_options.tcl
prompt> open_lib myTestLib
prompt> check_libcell_pin_access -mode cell_by_cell
```

Example 3) Reroute violated nets in cells with DRC violations.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.route.reroute_drc_cells_only -value true
prompt> open_lib myTestLib
prompt> check_libcell_pin_access -mode cell_by_cell -from route
```

Example 4) Report DRC on all routed cells.

```
prompt> open_lib myTestLib
prompt> check_libcell_pin_access -mode cell_by_cell -from report_route
```

Example 5) Derives cell spacing constraints.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.report.derive_cell_spacing_constraints -value
 cell_spc_rules.tcl
prompt> open_lib myTestLib
prompt> check_libcell_pin_access -mode cell_by_cell -from report_route
```

Example 6) Update placement for the DRC cells with the derived cell spacing file.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.place.cell_spacing_rule_file -value
 cell_spc_rules.tcl
prompt> open_lib myTestLib
prompt> check_libcell_pin_access -mode cell_by_cell -from place
```

---

check_license

Checks the availability of the specified license feature.

Syntax

status *check_license*

```
feature_name
[-quiet]
```

Feedback

Data Types

feature_name string

Arguments

feature_name

Feature name to be checked for existence in the license server.

-quiet

Do not print any error message if the check failed.

Description

The *check_license* command checks for the existence of the feature in the license server. It does not check out the license feature. If the feature exists on the server, the command returns 1. Otherwise, the command prints an error message and returns 0. The printing of this message can be suppressed via *-quiet* option.

The *list_licenses* command provides a list of the features that are currently checked out.

Examples

This example checks the availability of the Fusion-Compiler-AG license feature:

```
prompt> check_license Fusion-Compiler-AG
1
```

See Also

- get_licenses
- list_licenses
- remove_licenses

---

check_lvs

Checks for inconsistencies in the physical layout of the current design.

Syntax

status *check_lvs*

```
[-nets collection_of_nets]
[-checks {short open floating_routes all}]
[-max_errors maximum_number_of_errors]
[-check_child_cells true | false]
[-exclude_child_cell_types exclude_types]
[-check_zero_spacing_blockages true | false]
[-check_top_level_blockages true | false]
```

Feedback

```
[-open_reporting { bounding_box | detailed }]
[-report_floating_pins true | false]
[-treat_terminal_as_voltage_source true | false]
[-ignore_filler_cells true | false]
[-filler_cell_name_prefix specific_filler_cell_name]
[-include_net_type_specified_blockages true | false]
[-coordinte {{x1 y1} {x2 y2}}]
[-build_layer_connectivity_by_contact_code true | false]
```

Data Types

collection_of_nets	collection
maximum_number_of_errors	integer
exclude_types	list
specific_filler_cell_name	string

Arguments

`-nets` *collection_of_nets*

Specifies the nets to check. By default, all nets are checked.

`-checks {short open floating_routes all}`

Specifies the types of errors to check as follows:

- *short:* check for shorts between nets.
- *open:* check for open nets.
- *floating_routes:* check if any floating routes exist.
- *all:* check all error types above

By default, all error types are checked.

`-max_errors` *maximum_number_of_errors*

Specifies the maximum number of errors for each type of violations specified with the *-checks* option. Set the value to 0 to specify an unlimited error count. The default is 20.

`-check_child_cells true | false`

Specifies whether to check shorts between child cells and top-level shapes. If true, all shapes in child cells are checked. The default is true.

`-exclude_child_cell_types {`*exclude_types*`}`

Specifies cell types to ignore when checking shorts between child cell and top-level shapes. Specify one or more of the following cell types: *abstract*, *analog*, *black_box*, *corner*, *cover*, *diode*, *end_cap*, *fill*, *filler*, *flip_chip_driver*, *flip_chip_pad*, *lib_cell*, *macro*, *module*, *pad*, *pad_spacer*, *physical_only*, and *well_tap*.

Feedback

You must specify the *-check_child_cells* option with this option.

`-check_zero_spacing_blockages true | false`

Specifies whether to check shorts on zero spacing blockages. The default is false.

`-check_top_level_blockages true | false`

Specifies whether to check shorts on top-level blockages. The default is true.

`-open_reporting { bounding_box | detailed }`

Specifies how open violations are shown in the error browser.

- *bounding_box:* Report bounding box of open net
- *detailed:* Report the detailed open locations in the error browser; it might require longer runtime to find detailed open locations

When the number of connected components of an open net is more than 100 and the *-open_reporting* option is set to *detailed*, 100 approximated open locations will be reported. The default is bounding_box.

`-report_floating_pins true | false`

Specifies whether to report floating pins when checking open or floating_routes violations. The default is false.

`-treat_terminal_as_voltage_source true | false`

When set to true, the check_lvs command assumes that all terminals of pg nets are voltage sources. The default is false.

`-ignore_filler_cells true | false`

Specifies whether to ignore the filler cell checking. The default is false.

`-filler_cell_name_prefix` *`specific_filler_cell_name`*

Specifies different prefix in "create_stdcell_fillers". The default name of filler_cell_name_prefix is same as the prefix in create_stdcell_fillers. If you don’t specify different prefix in "create_stdcell_fillers", you don’t need to specify "-filler_cell_name_prefix" in check_lvs.

`-include_net_type_specified_blockages true | false`

Specifies whether the check_lvs command should awared net type specified routing blockages. If the option is specified, check_lvs will awared net type specified routing blockages and report the short if the net type specified routing blockage is short to specified net type shapes. The default is false

Feedback

`-coordinte {{x1 y1} {x2 y2}}`

Specifies the region for open check. If the option is specified, check_lvs will only the the open within the given bbox region

`-build_layer_connectivity_by_contact_code true | false`

When option set to true, check_lvs will build the layer connectivity from the contact code definied in tech file.

Description

The *check_lvs* command detects physical layout versus schematic errors. Violations discovered by the checker are available as an error set for browsing with the GUI error browser.

The command can use multiple CPU cores to generate the report based on the *set_host_options -max_cores* command setting. If this value is not set, the command runs on a single core.

The command generates an error file named "block_name"_lvs.err. To view the errors on GUI, load the error file by using the Error Browser. Users could also get information of errors by get_drc_errors and get_drc_error_types.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports shorts, opens, and floating route violations for all nets in the design.

```
prompt> check_lvs
```

The following example reports only short violations for all nets in the design.

```
prompt> check_lvs -checks short
```

The following example reports short, and open violations for net N1, N2, and N3.

```
prompt> check_lvs -nets {N1 N2 N3} -checks {short open}
```

The following example reports short violations without checking shapes in child cell.

```
prompt> check_lvs -checks short -check_child_cells false
```

The following example reports open violations in detail on error browser.

```
prompt> check_lvs -checks open -open_reporting detailed
```

The following example reports short violations without checking for filler cell.

Feedback

```
prompt> check_lvs -checks short -ignore_filler_cells true

The following example shows the way to get information of errors by
 get_drc_errors and get_drc_error_type command after executing check_lvs.

prompt> check_lvs -checks open
prompt> set error_data $design_lvs.err
prompt> set data [open_drc_error_data  $error_data]

prompt> #get number of open nets
prompt> sizeof_collection [get_drc_errors -of_objects
 [get_drc_error_types -error_data $data "Open"] -error_data $data]

prompt> #get name of the open nets
prompt> get_attribute [get_drc_errors -of_objects [get_drc_error_types
 -error_data $data "Open"] -error_data $data] objects
```

See Also

- check_routes
- set_host_options
- get_drc_errors
- get_drc_error_types

---

check_macro_pin_access

Check pin accessibility between abutted macro/pad related type cells for the reference libraries of current library.

Syntax

```
status check_macro_pin_access
-mode horizontal | vertical
[-from prepare | place | report_place | route | report_route]
[-to prepare | place | report_place | route | report_route]
```

Data Types

NA

Arguments

-mode horizontal | vertical

Specifies the checking mode with different cell abutment direction.

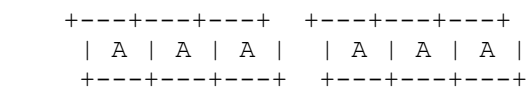
Feedback

This is a required argument.

- *horizontal*:

  The targe cells are put in horizontal direction, which can be set by the *pin_check.input.cells* application option.

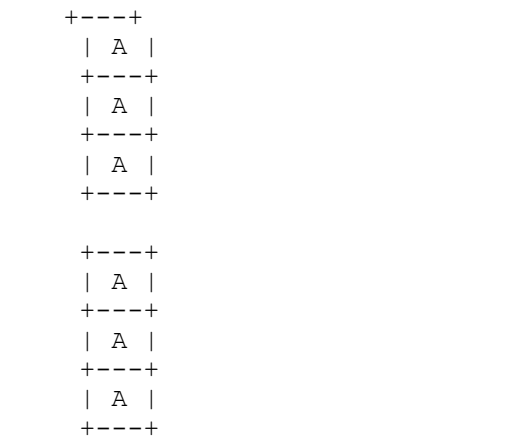
  A separate block is generated for each target cell, named "horizontal/cell_[refCellName].design". Here is an example of target cell A to against itself.



- *vertical*:

  The targe cells are put in vertical direction, which can be set by the *pin_check.input.cells* application option.

  A separate block is generated for each target cell, named "vertical/cell_[refCellName].design". Here is an example of target cell A to against itself.



`-from prepare | place | report_place | route | report_route`

Specifies the starting step for pin accessibility checking. The default value is "prepare".

For a new design library, user can only start from "prepare" step.

For an existing design library, user can start from next step of current state.

```
- If the test design is prepared already, user can start from
 "place".
- If the test design is placed already, user can start from
 "report_place" or "route".
```

Feedback

```
  - If the test design is routed already, user can start from
   "report_route".
```

User can also start from the step ahead the existing state to overwrite current result.

The option is ignored when *-mode* is analyze_lib_cell or analyze_lib_pin.

```
-to prepare | place | report_place | route | report_route
```

Specifies the ending step for pin accessibility checking. The default value is "report_route".

User can stop at any step behind the *-from* step.

```
  - When the command is ending at "prepare", the test design is
   prepared and saved.
  - When the command is ending at "place" or "report_place", the
   test design is placed and saved.
  - When the command is ending at "route" or "report_route", the
   test design is routed and saved.
```

Description

The *check_macro_pin_access* command performs pin accessibility checking on the target cell to against the cell itself in horizonal or vertical cell abutment.

The command supports macro/pad related design types, which are: macro, pad, analog, block_bbox, flip_chip_pad, flip_chip_driver, abstract, pad_spacer, module.

To control the spacing between abutment cells, please set *pin_check.place.macro_spacing*.

The command has five steps in the full checking process.

```
- "prepare": Creates test design for each target cell and generates cell
 combination and netlist.
  - "place": Initializes the floorplan and performs cell placement and
 legalization.
  - "report_place": Performs check_legality and reports the ligalization
 errors.
  - "route": Performs routing commands, such as route_auto, route_detail
 or route_eco.
  - "report_route": Performs check_routes and reports the routing DRC.
```

The command uses the *pin_check.** application options to control the whole checking flow, including six categories.

```
pin_check.input.*: setting for target cells, excluding cells, against
 cells, cell filter
  pin_check.common.*: general setting such as tech_node, netlist,
 parallel control, PG routing, ...
```

Feedback

```
 pin_check.analyze.*: setting for -mode analyze_lib_cell and
analyze_lib_pin
 pin_check.place.*: setting for placement and legalization
 pin_check.route.*: setting for routing
 pin_check.report.*: setting for signoff_check_drc and derive cell
spacing constraints
```

The command supports GRD-based parallel P&R.

```
set_app_options -as_user_default -name pin_check.common.grd -value true
  set_app_options -as_user_default -name pin_check.common.grd_command
 -value $grdCmd

  set_app_options -as_user_default -name
 pin_check.common.num_cells_per_run -value 20
  or
  set_app_options -as_user_default -name pin_check.common.num_jobs -value
 10
```

Limitations

Current library must exist and which is created by command *create_pin_check_lib*.

Examples

Example 1) Run pin accessibility checking in one run for all library cells. The preplaced option file is required for placement.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.place.preplace_option_file -value
 preplace_options.tcl
prompt> create_pin_check_lib myTestLib -technology a.tf -ref_libs MACRO
prompt> check_macro_pin_access -mode vertical
```

Example 2) Run pin accessibility checking in multiple jobs. Each job runs 5 cells in placing and routing.

```
prompt> set_app_options -as_user_default -name
 pin_check.common.num_cells_per_run -value 5
prompt> set_app_options -as_user_default \\
        -name pin_check.place.preplace_option_file -value
 preplace_options.tcl
prompt> open_lib myTestLib
prompt> check_macro_pin_access -mode vertical
```

Example 3) Reroute violated nets in cells with DRC violations.

```
prompt> set_app_options -as_user_default \\
        -name pin_check.route.reroute_drc_cells_only -value true
prompt> open_lib myTestLib
prompt> check_macro_pin_access -mode vertical -from route
```

Example 4) Report DRC on all routed cells.

Feedback

```
prompt> open_lib myTestLib
prompt> check_macro_pin_access -mode vertical -from report_route
```

---

check_mib_alignment

Checks the alignment of each multiply instantiated block (MIB) instance against power straps, ground straps, standard cell rows, and wire tracks in the current design.

Syntax

int *check_mib_alignment*

```
[-pg]
[-cell_row]
[-wire_tracks]
[-layers layers]
[-blocks blocks]
[-verbose]
```

Data Types

```
layers collection
blocks collection
```

Arguments

`-pg`

Checks the alignment of each MIB instance against the power and ground straps that intersect MIB instances in the current design. If any MIB instances are not aligned correctly with power and ground straps, the command issues a warning message with the location of the misalignment.

`-cell_row`

Checks the alignment of each MIB instance against standard cell rows and cell row site which intersect the MIB in the current design. If any MIB instances are not aligned correctly with cell rows or cell row site, the command issues a warning message.

`-wire_tracks`

Checks the alignment of each MIB instance against wire tracks in the current design. If any MIB instances are not aligned correctly with wire tracks, the command issues a warning message.

Feedback

`-layers` *layers*

Specifies the layers on which to check the alignment of MIB instances against power straps, ground straps, and wire tracks. This option is used with the *-pg* or *-wire_tracks* options.

`-blocks` *blocks*

Specifies the reference block name to which the MIB instances belong, for checking the alignment of MIB instances against power straps, ground straps, and wire tracks.

`-verbose`

Prints complete misalignment report for the checked MIB instances. Without this option, the command prints a compact report (default).

Description

This command checks alignment of each MIB instance against power straps, ground straps, cell rows, and wire tracks respectively or checks all of them without corresponding options. The misaligned MIB instances cannot be pushed down successfully. Misalignment messages are reported in GUI->Window->Message Browser Window when EMS database is created using command create_ems_database.

Examples

The following example checks for power and ground strap alignment across all the MIB instances in the design.

```
prompt> check_mib_alignment -pg -verbose
```

The following example checks for MIB alignment against wire tracks.

```
prompt> check_mib_alignment -wire_tracks -verbose
```

See Also

- push_down_objects
- report_mibs

---

check_mib_for_pin_placement

Checks multiply instantiated block (MIB) instances for potential pin placement issues.

Syntax

string *check_mib_for_pin_placement*

```
[-swapped_connections]
[-top_level_terminal_locations]
```

Feedback

```
[-asymmetric_connections]
[-cells list_of_blocks]
[-nets net_collection]
```

Data Types

```
list_of_blocks   list
net_collection   collection
```

Arguments

`-swapped_connections`

Checks and reports pins on MIB instances that do not connect to the corresponding pins across the instances of the reference block. The check can be run before and after pin placement. The check is limited to comparing two-pin nets that connect MIB instances.

`-top_level_terminal_locations`

Checks and reports top-level terminals that connect to the same MIB pin, but at difference locations. The check can be run before and after pin-placement.

`-asymmetric_connections`

Checks for pins across MIB instances where the MIB block pin does not connect to the same number or type of pins (asymmetric pins). The check can be run before and after pin placement. Unlike the *-swapped_connections* check, the *-asymmetric_connections* check is not limited to two-pin nets that connect two unique MIB instances. Instead, this check examines all MIB pins in the design for asymmetry. By definition, swapped connections are a subset of asymmetric connections. The command skips pins that are connected to tie-high or tie-low nets. When this option is used the command returns asymmetric connections/ pins as well as pins connected to these asymmetric connections to help with further analysis.

`-cells` *`list_of_blocks`*

Specifies a list of blocks or cells for checking. The check considers all the MIB blocks in the design for checking, but limits reporting and the collection of pins to the set of blocks specified in the *list_of_blocks*.

`-nets` *`net_collection`*

Specifies a collection of nets for mib checking. The check considers all the MIB blocks in the design for checking, but limits reporting and the returned collection of pins to those pins that connect to the specified set of nets. If this option is not specified the command looks at all MIB pins.

Feedback

Description

This command checks and reports potential multiply instantiated block (MIB) pin placement issues. If an issue is detected, the command returns a collection of pins with potential problems. The command can be used before or after pin placement to detect potential issues with MIB pins. You must specify at least one of *-top_level_terminal_locations* or *-swapped_connections* options.

The *set_editability* can enable/disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled by *set_editability*.

MIB pins that are dangling or tied-off are ignored by this command. That is the comparisons of MIB pin connectivity are limited to those pins that are neither dangling nor tied off.

Examples

The following example checks for swapped MIB pin connections pins on all blocks.

```
prompt> check_mib_for_pin_placement -swapped_connections
```

See Also

- place_pins
- report_feedthroughs
- set_editability

---

check_multibit_library

Reports the compatible multibit and single bit cells in the library for banking and debanking.

Syntax

status *check_multibit_library*

```
-stage rtl | physical | all
[-banking]
[-debanking]
[-combinational]
[-generate_map_file file_name]
```

Arguments

`-stage rtl | physical | all`

Specifies the stage, *rtl* or *physical*, to report compatible library cells, for RTL or physical banking and debanking, repectively. The value *all* reports the library compatibility information for both RTL and physical multibit stages.

Feedback

`-banking`

Reports all compatible multibit library cells for each single bit library cell for RTL banking stage, physical banking stage, or both if the value of *-stage* is specified to be *rtl*, *physical*, or *all*, respectively.

`-debanking`

Reports all compatible single bit library cells for each multibit library cells for RTL debanking stage, physical debanking stage, or both if the value of *-stage* is specified to be *rtl*, *physical*, or *all*, respectively.

`-combinational`

Reports all compatible single bit library cells for each combinational multibit cell.

`-generate_map_file` *file_name*

Specifies the name of output file that contains the mapping information. The file contains a series of function equivalent library cell groups for single bit cells. The file also contains the mapping of multibit bit-width to the combination of lower multibit library cells in each function equivalent group.

Description

This command lists all the compatible library cells for RTL and/or physical banking and debanking. The report also includes the reasons of incompatibility. The report lists the compatible and incompatible multibit library cells for each single bit library cell if the -banking option is specified. On the other hand, the report lists the compatible and incompatible single bit library cells for each multibit library cell if -debanking option is specified.

If the -generate_map_file option is specified, the output file is generated. The output file contains a collection of the functional equivalent library cells. The output file also shows how to use the lower multibit library cells to compose a multibit cell whose bit-width is under 32 for each function equivalent group. The -generate_map_file option is only applicable for the physical multibit stage.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example generates a compatible library cells report for RTL banking and debanking.

```
prompt> check_multibit_library -stage rtl -banking -debanking

****************************************
Report : check_multibit_library
Flow   : RTL BANKING
```

```
****************************************

--------------------------------------------------------------------------------

The following table lists the incompatible reasons and the details of the incompatibility.

```
|------------------------------|----------------------------------------
----------------------------------------------------------------------
-------------------------------------------------------------------|
| Reason for Incompatibility   | Comment

                                                                    |
|------------------------------|----------------------------------------
----------------------------------------------------------------------
-------------------------------------------------------------------|
| LIB_CELL_EXCLUDE             | The lib cell is excluded by
 "set_lib_cell_purpose -exclude" or the attribute "valid_purposes" of lib
 cell is not suitable.
    |
| DONT_USE                     | The lib cell is set to true by the
 "set_dont_use" command or the attribute "dont_use" of lib cell is set to
 true or the attribute "valid_purposes" of lib cell is not suitable.  |
| DONT_TOUCH                   | The lib cell is set to true by the
 "set_dont_touch" command or the attribute "dont_touch" of lib cell is
 set to true.
 |
| VOLT_INCOMPATIBLE            | PVT is not consistent for single bit and
 multibit library. Please check with the "report_pvt" command.
                                                                    |
| FRAME_VIEW_DOES_NOT_EXIST    | The lib cell frame view does not exist.

                                                                    |
```

Feedback

```
| SITE_HEIGHT_INCOMPATIBLE     | The cell height is incompatible with
 site height.
                                                                      |
| PIN_ORDER_MISMATCH           | Type of pins do not match for mapping
 given in "mb_pin_map" attribute of multibit lib cell. Scan pins are
 mapped to non-scan pins or vice-versa.                               |
| LIB_ARC_MISMATCH             | Please use "get_lib_timing_arcs" command
 to check arc mismatch between single bit and multibit lib cells.
                                                                      |

check_mv_design

Checks for violations in a multi-voltage design.

Syntax

status *check_mv_design*

```
[-max_message_count message_count ]
[-erc_mode]
[-voltage_threshold threshold ]
[-power_domain]
[-supply]
[-isolation]
[-level_shifter]
[-retention]
[-power_switch]
[-repeater]
[-terminal_boundary]
[-pgmux]
[-diode]
[-model]
[-tieoff]
[-pg_pin]
[-analog]
[-physical_block_pin]
[-signal_pin]
[-pg_netlist]
[-all]
[-interface_only]
[-objects]
```

Feedback

Data Types

message_count	integer
threshold	float

Arguments

`-max_message_count` *message_count*

Sets the maximum number of occurrences for each error type. If you set it to zero or 'all', that means the number of occurrences of the message is unlimited. If this option is not specified, the limit is 20 by default.

`-erc_mode`

If specified, the command runs in electrical-rule-checking mode and ignores any UPF strategies specified in the power intent. If this option is not specified, the command considers UPF strategies.

`-voltage_threshold` *threshold*

Sets the voltage threshold for level shifting violations. If this option is not specified, the threshold is zero by default.

`-power_domain`

Checks power domains of the design. This is optional.

`-supply`

Checks supply nets, supply sets and supply ports of the design. This is optional.

`-isolation`

Checks isolation strategies, isolation cells, and isolation of the design. This is optional.

`-level_shifter`

Checks level shifter strategies, level shifter cells, and voltage shifting of the design. This is optional.

`-retention`

Checks retention strategies, retention cells of the design. This is optional.

`-power_switch`

Checks power switch strategies, switch cells of the design. This is optional.

`-repeater`

Checks repeater of the design. This is optional.

Feedback

`-terminal_boundary`

Checks terminal boundaries of the design. This is optional.

`-pgmux`

Checks PG MUX of the design. This is optional.

`-diode`

Checks diode cells of the design. This is optional.

`-model`

Checks models of the design. This is optional.

`-tieoff`

Checks tie-off connections of the design. This is optional.

`-pg_pin`

Checks PG pin rule of the design. This is optional.

`-analog`

Checks analog nets of the design. This is optional.

`-physical_block_pin`

Checks physical block pins of the design. This is optional.

`-signal_pin`

Checks signal pins of the design. This is optional.

`-pg_netlist`

Checks pg nets and power and ground connections of the design. This is optional.

`-all`

Checks all the rules above of the design. This is optional.

`-interface_only`

Checks violations related to block boundary interface of current block and sub-blocks only and other internal violations are excluded. This is optional.

`-objects`

This option recieve a list of pins, or ports as input. It checks level shifting and isolation violations on the paths through the given pins and/or ports. The option must be specified with one of -level_shifter and -isolation, or both, and it is an error to specify -objects with the options other than -level_shifter or -isolation. The same violations will not be reported more than once.

Feedback

Description

The *check_mv_design* command checks multi-voltage related electrical rules for the design, and issues error and warning messages as appropriate.

By default, all multi-voltage checks except pg net and pg connection checks are included unless a specific type of checks or *-all* option is specified,

Examples

The following command prints all multi-voltage related violations in the design.

```
prompt> check_mv_design -all -max_message_count all

--------- Power domain rule ----------

---

check_netlist

Checks the netlist for any connectivity errors or violations and issues warning messages accordingly.

Syntax

int *check_netlist*

```
[-cells]
[-nets]
[-ports]
[-hierarchical]
[-multiple_designs]
[-summary]
```

Arguments

`-cells`

Specifies that netlist checks to be performed on cell instances. This option involves checking the input and output pin connections of the cell instances as well as the inside connections for hierarchical cell instances.

`-nets`

Specifies that netlist checks to be performed on nets. This option involves checking for drivers, loads and multiple drivers of a net. It also checks if a net is constant driven or it is three state net.

`-ports`

Specifies that netlist checks to be performed on ports. This option involves checking of the port connections such as whether an output port is being driven, an input port has a load.

`-hierarchical`

Performs the checks on the objects across all levels of physical hierarchy. This option is FALSE by default.

Feedback

`-multiple_designs`

Reports warning messages related to multiply-instantiated designs.

`-summary`

Displays a summary of the warning messages instead of one message per warning. This does not affect the way error messages are issued.

Description

The command checks the design for netlist connectivity errors and any design violations. This command gives a preliminary information about the state of the netlist and if there are any potential problems with the netlist. This informs about the potential errors that might occur during the later stages.

The command performs checks cells/nets/ports based on the options provided. The command by default performs checks on cells, net and ports. When no option is given, the *check_netlist* command performs checks for cells, nets and ports of the top level hierarchy. If *-hierarchy* is given, the command would perform the checks across all levels of physical hierarchy. The option *-multiple_designs* flags multiple instances of a module. If a module is instantiated in two different designs, a warning message is issued.

If an open EMS database exists before this command is executed, the messages are saved to the EMS databse. The Message Browser window in GUI provides a summary of the number of messages for each check type as well as each individual message.

This command has no dependency on scenario-specific information.

Examples

The check_netlist command displays the following information when no option is specified.

```
prompt> check_netlist

check_netlist_for_3d

Checks netlist for 3DIC die.

Syntax

status *check_netlist_for_3d*

`[-error_view` *`view_name`*`]`

Data Types

`view_name` `string`

Arguments

`-error_view` *`view_name`*

Specify the file name that would be used for GUI error browser.

Description

This command reports error if a port has more than one terminals which are on different side of a die.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example performs netlist check in a die.

```
prompt> check_netlist_for_3d
```

See Also

- check_design

check_objects_for_push_down

Checks a collection of nets or charging stations for potential problems before running the *push_down_objects* command.

Syntax

collection *check_objects_for_push_down*

Feedback

```
object_collection
[-cells cells]
```

Data Types

```
object_collection    collection
cells                collection
```

Arguments

object_collection

Specifies the collection of signal nets or charging stations to be checked. The collection can only include signal nets or charging stations, but not both. This option is required.

Only *signal_routing* objects and charging stations are checked by this command. The *signal_routing* objects include wires, paths, vias, via arrays and terminals that connect to signal nets. The charging stations are non-primary voltage areas that contain repeater buffers.

`-cells` *cells*

Specifies the block instances to check for pushing down objects. By default, all blocks are checked for push-down readiness.

Description

This command checks signal nets or charging stations for potential issues before pushing them into blocks with the *push_down_objects* command. The check returns a collection of nets or charging stations that might have problems. You can check only one object type, net or charging station, at a time.

If the command finds no problems with any of the objects passed (nets or charging stations), the command returns an empty collection. If the command encounters some problem unrelated to specific checks for objects, the command returns a "0" status rather than a collection.

When nets or shapes of nets are included in the object collection, this command traverses the routing and looks for 1) collinear routes and vias, 2) problems with physical routing that are incompatible with the logical definition of the net, 3) incomplete routing at the top level.

If charging stations are included, the command checks that the voltage area is non-primary and finds the deepest block that the voltage area overlaps. The depth of hierarchy that is examined is controlled by the *set_editability* command. Use this command to define the range of hierarchy depth or the blocks to check. The command checks if that block has the necessary UPF objects (PG supply nets) for receiving that voltage area.

This command uses the option settings specified by the *set_push_down_object_options* command. Set all options for the net or charging station objects that are planned for push-down before running the *check_objects_for_push_down* command.

Feedback

For net routing, the command checks the routing and determines whether feedthrough ports are required. By default, feedthrough requirements (such as top-level continuity, and logical-vs-physical consistency of the routing) are not checked unless the command detects pin constraints for the net that indicate that the *push_down_objects* command would be free to allow feedthroughs on the net. If so, and the routing requires a feedthrough port on the block, feedthrough requirements are checked for the net.

Feedthroughs for nets can be enabled or disabled by the *set_individual_pin_constraints -nets netname -allow_feedthroughs true|false* command.

Examples

The following example checks the routing objects for nets NETA and NETB for potential push down problems.

```
prompt> check_objects_for_push_down [get_nets {NETA NETB}]
```

The following example checks the charging station named "gas_station" for potential push down problems.

```
prompt> check_objects_for_push_down [get_voltage_areas gas_station]
```

---

check_pg_connectivity

Verifies physical connectivity of the power ground network.

Syntax

status *check_pg_connectivity*

```
[-nets pg_nets]
[-write_connectivity_file file_name]
[-check_macro_pins one | all | none]
[-check_block_pins one | all | none]
[-check_pad_pins one | all | none]
[-check_std_cell_pins one | all | none]
[-max_floating_cluster_size size]
[-remove_floating wire | via | all]
[-error_view_name file_name]
```

Feedback

Data Types

pg_nets	collection
file_name	string
size	integer

Arguments

`-nets` *pg_nets*

Specifies the power ground nets to be checked. By default, the command checks all power ground nets.

`-write_connectivity_file` *file_name*

Specifies the output file name. If specified, the tool writes detailed net connectivity information to the file.

`-check_macro_pins one | all | none`

Specifies how macro pins are checked for the specified nets. "one" means that a macro is connected if at least one pin shape of the net is connected. "all" means that a macro is connected only if all pin shapes of the net are connected. "none" means that macro pins are not checked. By default, the value is "one".

`-check_block_pins one | all | none`

Specifies how block pins are checked for the specified nets. "one" means that a block is connected if at least one pin shape of the net is connected. "all" means that a block is connected only if all pin shapes of the net are connected. "none" means that block pins are not checked. By default, the value is "all".

`-check_pad_pins one | all | none`

Specifies how pad pins are checked for the specified nets. "one" means that a pad is connected if at least one pin shape of the net is connected. "all" means that a pad is connected only if all pin shapes of the net are connected. "none" means that pad pins are not checked. By default, the value is "one".

`-check_std_cell_pins one | all | none`

Specifies how std cell pins are checked for the specified nets. "one" means that a std cell is connected if at least one pin shape of the net is connected. "all" means that a std cell is connected only if all pin shapes of the net are connected. "none" means that std cell pins are not checked. By default, the value is "one".

`-remove_floating wire | via | all`

Specifies how to remove the floating vias and wires identified by this command. If a floating via or wire belongs to a via matrix or shape pattern, then the occupancy position of the via or wire in the corresponding via matrix or shape pattern are set empty. "wire" means that all the floating wires should be

Feedback

removed. "via" means that all the floating vias should be removed. "all" means that all the floating wires and vias should be removed. By default, the floating vias and wires will not be removed if this option is not set.

`-max_floating_cluster_size` *size*

Specify the maximum size of floating cluster to be returned by the command and reported by the error browser.

`-error_view_name` *file_name*

Specifies the error view name. If not specified, the default error view name will be "[block_name]_floatingPG.err".

Description

This command checks the physical connectivity of the power ground network. The command generates information for floating wires, vias, pads, macro pins, and standard cell pins. Those wires/vias of disjoint groups are all floating objects. The information can be viewed by using the error browser. More detailed info can also be written to a file. The command also returns a collection of floating vias and wires. If some of the floating vias and wires belong to via matrixes and shape patterns, the corresponding via matrix and shape pattern objects will be returned. Use the -remove_floating option to remove the floating vias and wires.

Examples

The following example checks the connectivity of the VSS net, and checks whether all macro power ground pins are connected to the network.

```
prompt> check_pg_connectivity -nets VSS -check_macro_pins all
```

See Also

- check_pg_missing_vias

- connect_pg_net

---

check_pg_drc

Verifies and reports technology routing design rules violations and illegal overlaps of PG net objects.

Syntax

status *check_pg_drc*

```
[-nets {collection_of_nets}]
[-ignore_std_cells]
```

Feedback

```
[-do_not_check_shapes_in_lib_cells]
[-do_not_check_shapes_in_hier_blocks]
[-ignore_clock_nets true | false]
[-check_metal_on_track true | false]
[-ignore_keepout_margins]
[-check_min_metal_area_on_pins true | false]
[-load_routing_of_all_nets]
[-check_detail_route_shapes]
[-coordinates {{llx lly} {urx ury}}]
[-bottom_layer min_layer_name]
[-top_layer max_layer_name]
[-no_gui]
[-output text_file]
```

Data Types

collection_of_nets	collection or list
llx	float
lly	float
urx	float
ury	float
min_layer_name	string
max_layer_name	string
text_file	string

Arguments

`-nets {`*collection_of_nets*`}`

Specifies the PG nets to verify. By default, the shapes of all PG nets are checked. The set of specified nets should be a subset of all PG nets. All shapes of the specified nets are validated for DRC errors against all other PG nets in the design. If there are several PG nets in the design, such as VDD1, VDD2, VSS1, VSS2, you can choose to just check some PG nets. For example, you can choose to validate only VDD2 net shapes against the other PG nets.

`-ignore_std_cells`

Prevents the command from loading internal objects, such as pins and internal blockages, of standard library cells. This might be useful, for example, if placement of the cells is not "legalized". By default, the command loads and checks all internal objects of such cells.

`-do_not_check_shapes_in_lib_cells`

Prevents the command from reporting DRC errors that involve internal shapes of the same library cell only. Cells under this option include cells of the following design_type: lib_cell, filler, end_cap, well_tap, and diode. By default, such errors are reported. For example, a small unconnected pin included in the PG net might cause "minimal metal area" error in a report.

Feedback

`-do_not_check_shapes_in_hier_blocks`

Prevents the command from reporting DRC errors that involve internal shapes of any cell other than library cells described in this option, *-do_not_check_shapes_in_lib_cells*. For example, design_type macro, pad, and so on. By default, such errors are reported.

`-ignore_clock_nets true | false`

Specifies whether routing objects of clock nets should be ignored. By default, the tool ignores clock net objects.

`-check_metal_on_track true | false`

Specifies whether to check metal-shape alignment with a track on a metal layer (if corresponding rules are set in the technology file). By default, the tool does not do such checking.

`-ignore_keepout_margins`

Prevents the command from checking any overlaps of routing objects with keepout-margin areas. By default, all such cases are reported as illegal-overlap errors.

`-check_min_metal_area_on_pins true | false`

Specifies whether the command should check metal area of unconnected pins. By default, insufficient area of such pins is reported as an error.

`-load_routing_of_all_nets`

The tool considers existing routing shapes and vias of all nets for any DRC errors. By default, routing shapes and vias of non-PG nets are completely ignored. That is, by default, PG shapes and vias are verified against other PG shapes and vias. This option allows the checker to check existing routing shapes and vias of all nets. The shapes that are verified still need to be of type PG and should not have shape_use detail_route.

`-check_detail_route_shapes`

When this option is specified, the command takes into account routing shapes and vias of PG nets which have usage attribute "detail_route" or "shield_route". By default, such shapes are ignored. This holds for shapes to be verified and the shapes to be verified against. For checking against non-PG terminals, set the option as true.

`-coordinates {{`*`llx lly`*`} {`*`urx ury`*`} ...}`

Specifies a rectangular area where to perform design rule checking. *llx* and *lly* are coordinates that define the lower-left corner of the area. *urx* and *ury* are coordinates that define the upper-right corner. By default, PG DRC checking is performed on the entire design.

Feedback

When this option is specified, the tool considers objects within the specified rectangle, and nearby objects (that are within the range of DRC checker) associated with the PG nets.

`-bottom_layer` *`min_layer_name`*

Specifies the bottom routing layer on which to perform DRC checking. If this option is specified, the tool ignores objects on layers lower than *min_layer_name*. By default, the tool checks down to the lowest routing layer of the design.

`-top_layer` *`max_layer_name`*

Specifies the top routing layer on which to perform DRC checking. If this option is specified, the tool ignores objects on layers higher than *max_layer_name*. By default, the tool checks up to the highest routing layer of the design.

`-no_gui`

Prevents the tool from writing to the GUI error set. If this option is specified, a text report is written to the file specified by the *-output* option. If *-output* is not specified, the tool writes the report to a file named "./pg_routing_errors.txt".

`-output` *`text_file`*

Specifies the name of the output report file. By default, the tool does not write a text report, unless the *-no_gui* or this option is specified. If *-no_gui* is specified and *-output* is omitted, the tool writes the report to a file named "./pg_routing_errors.txt".

Description

This command verifies and reports violations of technology design rules and illegal overlaps of objects (shapes, vias, and pins) of power and ground (PG) nets.

By default, only the top-level shapes of PG nets whose shape_use attribute is set to any of the following values are verified for DRC errors: follow_pin, lib_cell_pin_connect, macro_pin_connect, pg_augmentation, ring, stripe, and user_route. Checking is performed either on the entire design area, or in the area specified by the *-coordinates* option.

The results from this command are available as an error set for browsing with the GUI error browser, or as text report that is written to a file (when the *-no_gui -output* options are specified), or both.

For the text report, the command writes the error type, violated rule, layer, and other details regarding the error as follows.

```
================
Error type:      insufficient space between two diff-net via-cuts
Violated rule:   Cut-Min_Spacing-Rule
Layer:           CO
Minimal spacing: 0.05
```

Feedback

```
Actual  spacing: 0.0238(southwest - northeast)
Spacing box:     {900.621 412.336} {900.633 412.357}
Via #1:          box = {900.579 412.294} {900.621 412.336}
                       net = VDD
Via #2:          box = {900.633 412.357} {900.675 412.399}
                 net = VSS
```

The command can use multiple CPU cores to generate the report, based on the *set_host_options -max_cores* command setting. If this value is not set, the command runs on a single core and therefore the report generation might be slower.

Examples

The following example checks technology design rules for all PG nets in the entire design. The report is generated as an error set for the GUI error browser. The command can use up to six CPU cores:

```
prompt> set_host_options -max_cores 6
prompt> check_pg_drc
```

The following example checks only objects of the VDD net on layer MET4. The text format report is written to a file named "./net_vdd_on_M4.drc":

```
prompt> check_pg_drc -no_gui -output ./net_vdd_on_M4.drc -nets VDD \\
   -bottom_layer MET4 -top_layer MET4
```

The following example checks rules within the specified rectangular area and generates both kinds of report:

```
prompt> check_pg_drc -coordinates {{287.0 362.0} {412.0 530.0}} \\
   -output ./PG-errors_in_window.txt
```

---

check_pg_elevation

Checks if power elevation cells, nets and ports are rightly inserted and if the coverage meets the requirement.

Syntax

status *check_pg_elevation*

```
[-bbox bounding_box]
[-percent_goal percent_goal]
[-prefix name_prefix]
[-max_route_layer layer_name]
```

Feedback

Data Types

```
bounding_box      list
percent_goal      float
name_prefix       string
layer_name        string
```

Arguments

`-bbox` *bounding_box*

Specifies the area in which check needs to be performed.

{{*llx lly*} {*urx ury*}}

`-percent_goal` *percent_goal*

Specifies the expected coverage.

`-prefix` *name_prefix*

Specifies the prefix to name new cells, nets and ports.

`-max_route_layer` *layer_name*

Specifies the maximum routing layer for port creation.

Description

This command scans the area indicated by *-bbox. If not specified, entire core area is scanned.*

It reports what percent of this area has power elevation modules inserted. It also reports if the coverage is upto the expected value specified by *-percent_goal.*

It performs some additional checks to ensure pins of PE modules are routed correctly to *-max_route_layer and ports are created.*

Examples

```
prompt> check_pg_elevation -percent_goal 25 \\
    -bbox {{10 50} {50 85}} \\
    -prefix "pe_" -max_route_layer M5
```

---

check_pg_missing_vias

Checks missing vias within the power and ground network.

Syntax

status *check_pg_missing_vias*

```
[-nets pg_nets]
[-within_bbox bboxes]
```

Feedback

```
[-via_rule_file rule_file_name]
[-output_file output_file_name]
[-write_default_via_rule_file]
[-shape_use shape_use_list]
[-ignore_shield_route]
[-ignore_small_intersections]
[-honor_routing_blockage]
[-filter_by_drc]
```

Data Types

```
pg_nets           collection
rule_file_name    string
output_file_name  string
shape_use_list    list
```

Arguments

`-nets` *pg_nets*

Specifies the PG nets to be checked. By default, the command checks all PG nets.

`-within_bbox` *bboxes*

Specifies a bounding box or a list of bounding boxes within which you can check the missing PG vias.

`-via_rule_file` *rule_file_name*

Specifies the via rule file which includes all the via rules to be checked. By default, the command checks vias between adjacent orthogonal layers.

The via rule file can include multiple via rules.

The supported rules are

- *stack_via*: Checks for stacked vias.

  By default (*false*), this rule is not checked.

- *parallel*: Checks for vias between parallel layers.

  When you specify this rule, you must also specify the pitch with the *pitch* attribute.

  By default (*false*), this rule is not checked.

- *pitch* Specifies the via pitch for parallel wires.

- *macro_pin*: Checks for vias connecting to macro or power-switch PG pins.

  By default (*false*), this rule is not checked.

Feedback

- *terminal*: Checks for vias from terminal in upper layer to wires in lower layer

  By default (*false*), this rule is not checked.

The via rule format is as follows:

```
viaRuleName {
  bottom_layer: bottom_metal_layer_name (required)
  top_layer: top_metal_layer_name       (required)
  stack_via: true | false
  parallel: true|false
  pitch: number
  macro_pin: true | false
  terminal: true | false
}
```

The following example checks vias between M2 and M7, including stacked vias and macro pins.

```
viaRule1 {
  bottom_layer: M2
  top_layer:    M7
  stack_via:    true
  macro_pin:    true
!}
```

`-output_file` *output_file_name*

Specifies the output file name. If specified, the tool writes detailed information about missing vias to the file.

`-write_default_via_rule_file`

Writes the default via rule to defaultViaRule.txt.

`-shape_use`

If specified, the command will only check vias against shapes with specified shape_use in the option. If not specified, the command will check vias against shapes with all shape_use.

`-ignore_shield_route`

If specified, the command will not check vias against shapes with shape use shield_route.

`-ignore_small_intersections`

If specified, the command will not report error if the via site is smaller than the minimum contact code on the layer.

Feedback

`-honor_routing_blockage`

If specified, the command will not report error if the via site is covered by routing blockages.

`-filter_by_drc`

If specified, the command will not report error if the via site is found in the error browser as a DRC error by a command using the *-show_phantom* option.

Description

This command checks for missing vias between overlapping regions of different metal layers. The error info can be viewed from error browser or written to a file. You can define via rules to be checked by writing the rules to a file and importing the file with the *-via_rule_file* option.

Examples

The following example checks the vias for the VSS net based on rules defined in viaRule.txt.

```
prompt> check_pg_missing_vias -nets VSS -within_bbox {{900 900} {1100
 1100}} -via_rule_file viaRule.txt
Check net VSS vias...
Number of missing vias: 0
Checking net VSS vias took 0 seconds.
```

See Also

- compile_pg

---

check_physical_constraints

Checks the design for any issues in the floorplan objects and constraints such as macro or fixed cell instances, site rows, blockages, core/die area, layers, tracks, bounds, and so on.

Syntax

int *check_physical_constraints*

Arguments

This command has no arguments.

Description

The command checks the design for any issues with the physical constraints. Use this command to discover potential issues which could lead to problems later in the

Feedback

flow. Depending on the severity, the command issues an information, warning, or error message.

The command checks whether floorplan data is available or not, and checks for the presence of core and die areas. It also performs various checks on site rows, move bounds, group bounds, layers, tracks, fixed and macro cell instances, and placement blockages.

Basic Floorplan:

The command checks that basic floorplan information, like boundary and core, is defined for the block or that the information is valid. Checks if the unit tile is missing in reference library.

Site Rows:

Checks if the site height is multiple of the normal site height.

Checks if the site row overlaps another site row.

Checks if the site row needs to be aligned.

Checks if there are both horizontal and vertical site rows.

Checks if it is a non-zero extra spacing in rows which is not supported.

Cell Instance:

Checks if the keepout margin is outside the core area.

Checks if the I/O pad cell instance is in the core area or overlaps with other cell instance.

Checks if the orientation of cell instance is legal.

Checks if the macro is placed and fixed.

Checks if the macro is out of the core area.

Checks if the macro is overlapping with other macro or blockage.

Placement Blockages/Bounds:

Checks if the movebound is completely covered by blockage.

Checks if the placement blockage is partially or completely outside the core area.

Checks if the move bound is partially or completely overlap with other.

Checks if the utilization of group bound/move bound is above 90%.

Layers/Tracks:

Checks if the tracks are defined.

Feedback

Checks if the track crosses core area.

Checks if the preferred routing direction is defined.

Checks if the consecutive metal layers have the same preferred routing direction.

Checks if the layer spacing is greater than the pitch minus width.

Checks if a layer has non-PG shapes/shape patterns on it.

Checks if a layer is defined in the technology file.

If an open EMS database exists before this command is executed, the messages are saved to the EMS database. The Message Browser window in the GUI provides a summary of the number of messages for each check type as well as each individual message.

This command has no dependency on scenario-specific information.

Examples

The *check_physical_constraints* command displays the following information.

```
prompt> check_physical_constraints
****************************************

Feedback

Data Types

tolerance_distance	float
file	string
tolerance_ratio	real
view_name	string
net_collection	list
net_length	real
directory	string
pins	collection
ports	collection
list_of_objects	list

Arguments

`-alignment true | false`

Checks block pin alignment QoR. The alignment check is limited to two-pin nets with at least one connection to a block (or Hard-Macro/ETM if the appropriate *-cell_type* option is used) and no connection to a standard cell pin. Nets not connected to a block or connected to standard cell pins, or those with more than two connections, are not checked. Nets are not checked if they are connected to blocks that are disabled for planning. When used with the *-self* option the check is limited to two-pin nets with one connection to a top-level terminal (and no connection to standard-cell pins).

If this option is not specified, the command skips alignment checking. Note that two pins are considered unaligned if their pin bounding boxes are misaligned by greater than the *-alignment_tolerance_distance*. But if the tolerance option is not used and the bounding boxes of two pins overlap and the extent of the overlap is greater than two-thirds of smaller bounding box then pins are not considered to be unaligned.

On the other hand if the *-alignment_tolerance_distance* is specified/used then that distance is used to compute alignment.

Note that by using the option along with the *-cell_type* option, alignment can be checked between hard macro to hard macro instances or ETM to ETM cells.

`-alignment_tolerance_distance` *`tolerance_distance`*

Checks that pins are aligned within the specified *tolerance_distance*. The command only reports misaligned pins when the distance between two pins is greater than specified *tolerance_distance*. The distance is the vertical distance if two pins are on horizontal layers, or the horizontal distance if two pins are on vertical layers. The distance is to be specified in microns. You must use the *-alignment true* option with the *-alignment_tolerance_distance* option. When this option is not specified the default value of zero microns is used.

Feedback

`-layer_mismatch_only true | false`

Limits the alignment check to two-pin nets that are aligned but have pins on different layers. This option can be used only with the *-alignment* option. When set to true, the summary report, detailed net report, and list of violating pins returned, all correspond to only such nets.

The default is false for this option.

`-blocked_only true | false`

Limits the alignment check to two-pin nets that are aligned but are blocked by a physical block (or hard macro) between the two pins. This option can be used only with the *-alignment* option. When set to true, the summary report, detailed net report, and list of violating pins returned, all correspond to only such nets. Note that if the physical block is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

`-alignment_report_file` *`file`*

Specifies the name of the file where the detailed net alignment reports are written. This option can only be used with the *-alignment* and *-report_net_details* options.

`-alignment_histogram true | false`

This option is used to generate a histogram of the misaligned nets that are alignable. The histogram is based on misaligned distance. The nets are grouped in buckets of 50 microns according to their misaligned distance. The option can be used only with the *-alignment* option. The default value is false.

`-connection_type ALL | BLOCK_TO_BLOCK | BLOCK_TO_MACRO | BLOCK_TO_IO`

Limits the alignment check to two-pin nets of the specified type. This option can be used only with the *-alignment* and *-single_pin* options.

For the single pin check, specifying this switch limits single pin checking to that subset of interfaces. For example between only blocks and hard-macros. Note that this option cannot be used with the *-cell_type* option.

If this option is not specified, the default is ALL, which runs the check on all the two-pin nets in the design.

`-cell_type ALL | BLOCK | HARD_MACRO | EXTRACTED_TIMING_MODEL`

Directs the command to check the pins of only the specified type of cells. The default value is BLOCK, which limits the checking only to pins on physical blocks. The option cannot be used in conjunction with the *-self* option.

Pin checking on Hard-Macro and Timing-Model instances is limited only to short, preroute, missing, single-pin , alignment, wire-track and wide-track checks. This

Feedback

option is silently ignored for all other checks and the remaining checks will only run on pins of physical blocks.

When the value specified is ALL, then block ETM and hard-macro pins are checked for appropriate violations.

`-pin_type ALL | SIGNAL_PINS | PG_PINS`

Directs the command to check the pins of only the specified type, that is either power/ground or signal pins or both.

The default is signal_pins, which limits the checking only to pins on physical blocks connected to signal nets.

A pin is considered a power/ground pin by the checker if it connected to a power/ground net and is itself also of the power/ground type. The *place_pins* command also treats PG nets/pins similarly (refer to its man-page for relevant details).

PG (power/ground) pin checking is limited only to the short, single-pin, missing wire-track, wide-track and pin-size checks. This option is silently ignored for all other checks and the remaining checks will only run on signal pins.

When the value specified is ALL, both signal and PG pins are checked for appropriate violations.

Using this option along with the *-nets* , *-pins* or *-ports* options results in filtering of the specified set (of nets, pins or ports) according to the passed pin type value. That is, if pin-type SIGNAL is used along with *-pins*, then only those pins from the set of pins that are of type SIGNAL are used for pin checking.

Note that short and spacing violations of signal pins with power/ground pins is checked by default, that is even when the value for this option is signal_pins. When the value is set to ALL then short violations between two PG pins are also checked. Note that checking for spacing violations between two PG pins is not supported.

`-corner_keep_out true | false`

Checks for corner keepout violations on the edges of physical blocks. If this option is not specified, the command skips the check.

The default is false for this option.

`-detour_tolerance` *`tolerance_ratio`*

Checks that the net detours are within the specified *tolerance_ratio*. You must use the *-pin_detour true* option with the *-detour_tolerance* option. *tolerance_ratio* is the ratio of the total bounding box over the standard cell bounding box. The command reports only nets with the ratio of the total bounding box to the standard cell bounding box that is greater than the specified value. The default

Feedback

tolerance_ratio is one. The details about standard cell bounding box and total bounding box are as follows:

- standard cell bounding box - Smallest rectangle that encloses all the standard cells that are connected to the net.
- total bounding box - Similar to the standard cell bounding box but includes the block pins. If the block pins are within the standard cell bounding box, the ratio is 1.0. When the block pins are outside the standard cell bounding box, the total bounding box is bigger than the standard cell bounding box and the ratio is greater than 1.0, which indicates a misalignment.

`-error_view` *`view_name`*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it is ignored. If no extension is specified, the file name is appended with the ".err" extension.

If this option is omitted, the error view data is stored as an attachment to the design database. When the design is closed and saved, the error view data is saved to the design database as well. The saved error view data does not change until the next *check_pin_placement* command.

`-exclude_unplaced_objects true | false`

This option can be used with the *-alignment* or *-pin_detour* options. When used with the alignment option, it excludes nets that have unplaced connections from the alignment check, when set to true. In this context (when used with alignment check), "Un-Placed" refers to a pin on an unplaced cell.

When used with the detour check it skips unplaced cells and dangling block pins from the detour computation. For details on how such dangling pins are handled by default refer to the *-pin_detour* option description.

By default, this option is false.

`-filename` *`file`*

Specifies the name of the file where the reports of pin placement checking are written. Cannot be used in conjunction with *-output_directory* option

`-layers true | false`

Determines if pins are placed on legal metal layers as specified by the *-allowed_layers* option of the *create_block_pin_constraint* or the *set_individual_pin_constraints* command. The command also checks for violations of any per-edge layer constraints that are specified in the pin-

Feedback

constraint file. For information about the default minimum and maximum metal layers used for pin placement, see the *create_block_pin_constraint* command man page.

For pins that are connected to and covered by a top-level terminal, the check ensures that such pins are on the same layer as that top-level terminal. Individual or block-level layer constraints are not checked for such pins.

If this option is not specified, the command skips the layer check.

The default is false for this option.

`-location true | false`

Determines if pins with location constraints are placed on their constrained location. Both on-edge and off-edge pins are checked against their location constraints.

For information about setting location constraints on pins review *set_individual_pin_constraints* command. If this option is not specified, the command skips the location check. The default is false for this option.

`-missing true | false`

Reports block pins without a pin shape. By default, this option is true.

`-nets` *`net_collection`*

Limits the pin placement check to the specified collection of nets.

`-net_length` *`net_length`*

Limits the detour check to only those nets whose length is greater than the specified value. The default is zero microns, which means that all nets are checked for detour. Currently this option can only be used with the *-pin_detour true* option. The units for *net_length* are microns. If routing is present for the net, the total length of the route is used. Otherwise, half the perimeter wire-length (from the bounding box of the net) is used to calculate the length.

`-off_edge true | false`

Determines if part of a pin outline coincides with an edge. A block cell pin is flagged if none of the pin edges coincide with its block edges. If this option is not specified, the tool skips the off edge check.

The default is false for this option.

`-offset true | false`

Checks if pin-placement violates (in decreasing order of priority) individual, topological or bundle pin offset constraints. If multiple constraints exist on the

Feedback

same pin (say individual and bundle for example) then the constraint with higher priority is given precedence and checked against.

If this option is not specified, the command skips the check. Note that even if the offset option is used without the *-side* option explicitly set to true, the command automatically runs the sides check as well. If certain pin/port placement already violates side constraints, it will automatically skip for offset checking.

If a range is specified (when specifying the offset constraint) then the pin's placement is checked against that range. If a specific offset is specified then the pin should be placed either at that offset or at the closest valid wire-track to that offset.

The default is false for this option.

`-order true | false`

Checks pin placement for order constraint violations. The order constraints specified in pin-constraint file with the *read_pin_constraints* command are used for this check.

The default is false for this option.

`-output_directory` *`directory`*

Writes individual report files for each check (layer, offset, side, and so on) to the specified directory. If the directory does not already exist, the command tries to create the directory. If creation is successful and write permissions are appropriate, the command checking output is written to individual files created in this directory instead of the prompt. The files created also have a list of pins associated with the particular violation. The option cannot be used together with the *-filename* option. If you omit the *-output_directory* option and specify the *-filename* option, the command writes a single file that combines the checks.

`-pins` *`pins`*

Limits the pin placement check to the specified collection of pins.

`-pin_blockage true | false`

Checks if a pin overlaps with an associated pin blockage or if the terminal of the pin abuts to or overlaps with a routing blockage, and if the layer of the pin is the same as the layers associated with the blockage. If this option is not specified, the command skips the pin blockage check.

The default is false for this option.

`-pin_detour true | false`

Checks for pin_detour violations. The option is used to report pins that might not be optimally placed. The check reports nets that have a bounding-box greater

Feedback

than the bounding box of the standard-cell pins and top-level terminals/ports that it connects.

The check runs on nets that have at least two pins with a minimum of one block pin. This includes nets that connect top-level ports/terminals to block pins. Pins that are unplaced are not included in the bounding box comparison. Also unconnected or dangling block pins are accounted for by projecting the center point of the standard-cell bounding box (corresponding to the nets connections) onto the edge of the dangling block pins. These projected points are added to the standard-cell bounding box to compute a more meaningful detour ratio in the presence of dangling connections.

When this option is used along with the *-self* option, it limits the detour checking to only those nets that have a connection to a top-level port in addition to having at least one block pin.

The option *-exclude_unplaced_objects* can also be used along with this option to filter out or skip dangling block pins from the detour computations. When set to true, block pins that have no external connections or those whose external connections are only other dangling block pins are excluded from the detour computations.

When the application option *plan.pins.detour_supernet_mode* is used the detour check skips over repeaters and considers the flat net during detour computation. Note that the path based option has precedence over the supernet based option. See the man pages of these options for more details.

Note that a net is skipped for detour checking if all the physical blocks it connects to are disabled.

The default is false for this option.

`-path_detour true | false`

Checks for path_detour violations. The option is used to report pins that might not be optimally placed. The check reports nets that have a bounding-box greater than the bounding box of the driver and load registers and top-level terminals/ports that it connects.

The check runs on nets that have at least two pins with a minimum of one block pin. This includes nets that connect top-level ports/terminals to block pins. Pins that are unplaced are not included in the bounding box comparison. Also unconnected or dangling block pins are accounted for by projecting the center point of the standard-cell bounding box (corresponding to the nets connections) onto the edge of the dangling block pins. These projected points are added to the standard-cell bounding box to compute a more meaningful detour ratio in the presence of dangling connections.

Feedback

When this option is used along with the *-self* option, it limits the detour checking to only those nets that have a connection to a top-level port in addition to having at least one block pin.

The option *-exclude_unplaced_objects* can also be used along with this option to filter out or skip dangling block pins from the detour computations. When set to true, block pins that have no external connections or those whose external connections are only other dangling block pins are excluded from the detour computations.

When the application option *plan.pins.detour_supernet_mode* is used the detour check skips over repeaters and considers the flat net during detour computation. Note that the path based option has precedence over the supernet based option. See the man pages of these options for more details.

Note that a net is skipped for detour checking if all the physical blocks it connects to are disabled.

The default is false for this option.

`-detour_consider_pin_constraints true | false`

This option can be used with the *-pin_detour* or *-path_detour* options.

When this option is true, pin_detour checking takes pin location constraints into account, then reports nets that have a bounding-box greater than the minimum bounding box of the standard-cell pins, top-level terminals/ports that it connects, and pin location constraints.

When this option is true, path_detour checking takes pin location constraints into account, then reports nets that have a bounding-box greater than the minimum bounding box of the driver and load registers, top-level terminals/ports that it connects, and pin location constraints.

The default is false for this option.

`-pin_density_map true | false`

Checks and reports on the prompt and the GUI the block pin density on the edges of each physical block in the design. The report is per layer and each edge is subdivided into buckets or windows for density computation. The density on each layer in each bucket is defined as the ratio of the number of pins by the number of available slots/wire-tracks (on that layer) within the bucket/window. The text version of this report is automatically redirected into a new file called block_pin_density.rpt created in the current working directory. If the directory is not editable or the file cannot be created, a warning is issued and the report is instead redirected to the prompt.

The option *-window_length* can be used to control the size of the window. If not specified a default window size as a multiple of site row height is used.

Feedback

The default is false for this option.

`-pin_direction true | false`

Checks for pin direction mismatch violations. The pin direction mismatches are divided into two categories:

- Abutted or stacked pin direction mismatch
- Multi-driven or floating net pin direction mismatch-for pins that connect hierarchical physical blocks

Abutted pins refer to two pins that are connected by the same net and are on two physical blocks of the same physical hierarchy. Stacked pins refer to two pins that are connected by the same net and are on two hierarchical blocks, where one block is the parent of another.

Power, ground, or tie-off nets are not checked for pin direction mismatch.

For a pair of abutted pins, the following pin directions are allowed and do not result in any violation errors:

- One of the pins is an input pin while the other is an output pin
- One of them is an inout pin while the other can be input, output, or an inout pin

For a pair of stacked pins, the following pin directions are allowed and do not result in any violation errors:

- Both pins are input pins or both of them are output pins
- One of them is an inout pin while the other can be input, output, or an inout pin

For a net that is neither multi-driven nor floating, there must be only one driver:

- The driver pin can be of input, output or inout direction
- If the driver pin is of input or output direction, any pin with the inout direction is considered as the load pin.
- If there is no driver pin with input or output direction, one pin with the inout direction is considered as the driver pin. And other pins with the inout direction are considered as loads if they exist.

The default is false for this option.

Feedback

`-pin_guide true | false`

Checks if the center of a pin is outside the associated pin guide and if the layer of a pin is NOT on a layer specified by the pin guide. If this option is not specified, the command skips the pin guide check.

The default is false for this option.

`-pin_mask_constraint true | false`

Checks if there are any mask_constraint violations on the block pins, such as abutted block pins with conflicting mask_constraint settings, block pin and wire track with conflicting mask_constraint settings, and so on. When checking if the block pin and the wire track have conflicting mask_constraint settings, the tool only checks the wire track owned by the block. If the block does not have a wire track within it, then the tool checks the block pin against top-level wire track instead.

By default, this option is false.

`-pin_size true | false`

Checks if pins honor their width and length constraints. If the pins do not have width or length constraints, but are on the double patterning layers, this option checks if the pins honor the default double patterning pin length requirement. If pins have width and length constraints and are also on double patterning layers, this option checks only if the width and length constraints are honored. If there are nondefault routing rules associated with the pin that have size/width constraints, those are checked as well. If a pin is placed on a wire track with nonzero track width, then the command checks to ensure that the pins width is the same as the track width.

If there is a min-area rule specified on the technology file for the layer, then the pins-area is checked against this rule.

It also checks to ensure that the pin-length is a perfect multiple of the grid size (if a grid is present/defined). For detailed explanation of the handling of pin length, width and area constraints, see the man page for the *place_pins*

The default is false for this option.

`-pin_spacing true | false`

Determines if any of the following object-pairs along the edge (the two objects overlap in the direction perpendicular to the edge), are closer than the number of wire tracks (or distance) specified by the *-pin_spacing* option of the *create_block_pin_constraint* or the *set_individual_pin_constraints* command.

- two signal pins

Feedback

- a signal pin and a power/ground pin (Note that spacing between two power/ground pins is not checked.)

- a signal pin and a preroute shape/via

If there are nondefault routing rule constraints associated with the pin (or associated net) then the spacing is checked against those constraints as well. The command also checks for violations of any per-edge layer constraints that are specified in the pin-constraint file.

The report has subsections for these different type of constraints. Note that the spacing check between pins is limited to pins on the same block edge.

If this option is not specified, the pin spacing check is not performed.

The default is false for this option.

`-technology_spacing_rules true | false`

Determines if any two signal pins (or a signal pin and power/ground pin) or a signal pin and a preroute are closer than any of the technology related spacing constraints. The supported spacing rules that are checked are the corresponding layers minimum spacing rule (as defined in technology file), fat-metal spacing rules and basic, color-based span spacing rules that might be defined in technology file.

Note that spacing is only checked for pins/shapes along a block edge. That is off-edge pins are not checked for spacing violations. Also preroute shapes from inside a hard-macro are not considered when checking spacing.

For two objects to be checked for spacing (except for end to end spacing), they must overlap in the direction perpendicular to the edge. End to end spacing checks the spacing between the ends of two objects (signal pins and signal/PG routing shapes), for objects to qualify for end to end spacing they must overlap in the direction of the edge (without being shorted together). Note that the spacing check between pins is limited to pins on the same block edge.

The report has subsections for these different type of rules. Note that spacing between two power/ground pins is not checked and that the *-pin_spacing* option only checks user specified constraints (like block or individual pin spacing constraints) and this option checks only technology related rules/constraints.

The default is true for this option.

`-ports` *`ports`*

Limits the pin placement check to the specified collection of ports.

Feedback

`-pre_route true | false`

Determines if any pin is shorted with any preroute (signal or power/ground) or via. The check is used to ensure that no pins overlap with and are on the same layer as a section of preroute. Note that the *-shorts* option does not check for shorts against preroute.

Note that even when used with the *-cell_type HARD_MACRO* option the checker does not load and check against any preroutes that might exist inside the hard-macro. It does however check the hard-macro pins for shorts against any preroutes that are created outside the hard-macro itself.

The default is true for this option.

`-report_net_details true | false`

Reports detailed net information on pins with alignment violations. You must use the *-alignment true* option with the *-report_net_details* option. If this option is not specified, the command does not include net details in the report output. When the *alignment_report_file* option is used the report is written to that specified file.

The following definitions are relevant to this report :

Aligned: The distance between the two pins is less than specified *tolerance_distance*. The distance is the vertical distance if two pins are on horizontal layers, or the horizontal distance if two pins are on vertical layers. The default value of *tolerance_distance* is zero microns.

Unaligned: The distance between the two pins is more than the specified *tolerance_distance*.

Blocked: There is a physical block (including hard macros) along the line between the two pins of the net. Note that if the physical block (that lies along the line between the two pins of the net) is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

Unblocked: There isn't a physical block or hard macro along the line between the two pins of the net. Note that if the physical block (that lies along the line between the two pins of the net) is a hard-macro the net is only considered blocked if there is a routing-blockage (on appropriate layer) inside the hard-macro that overlaps the nets bounding-box/path.

Unalignable: The pins of the net are unalignable due to some combination of pin side, pin-blockages, pin-guides corner-keepout constraints and the relative placement of the blocks. Pins of two child blocks that are not on facing edges are considered unalignable. A net that connects a parent block port/pin to a pin on the parents child block is considered alignable if it possible to align the two pins of the net by placing the parent block port/pin on another allowed side.

Feedback

Alignable: These nets are alignable given the constraints listed above. Most typically two pin nets are considered alignable when the pins are placed on facing edges.

The report is divided into 5 parts: (1) aligned nets on different layers, (2) aligned blocked nets, (3) unaligned alignable nets, unblocked, (4) unaligned alignable nets, blocked, (5) unalignable nets. Each section begins with one of the following commented header lines to indicate the type of unaligned or aligned nets.

- aligned nets on different layers:
- aligned blocked nets:
- unaligned alignable unblocked nets:
- unaligned alignable blocked nets:
- unaligned unalignable nets:

Following the header line, the report lists the details of each aligned or misaligned net. The details include the name of the net and its two pins, the type of the net/connection and whether the net is aligned or misaligned. The report also reports if the net is blocked/unblocked and if either pin is fixed.

The connection is between two pins that are from a block cell or top design (BLOCK), top-level I/O pins (IO), pad cell(PAD) or hard macro(HM). One of the pins must connect to a block cell. The following shows an example connection:

```
Two-Pin net {NetName} with pins {PinA} and {PinB} of type
 BLOCK->IO
is aligned. The net is blocked. {PinA} is Fixed.
```

For nets that are unalignable, the reason that they cannot be aligned is provided.

The default is false for this option.

`-routing_corridor true | false`

Checks if a pin does NOT touch the associated routing corridor or if the layer of a pin is NOT on a layer specified by the corridor. If this option is not specified, the command skips this check.

For nets with feedthrough pins, the checking depends on the properties of the routing corridor. If the routing corridor is connected and covers all its associated pins/ports, then each pin (including feedthrough pins) created by pin-placement should be within the routing corridor. If the routing corridor is not fully connected or does not cover all its associated pins/ports, then at least one of the original or feedthrough pins (per block) should be within the corridor.

Feedback

In addition, if there is no overlap between a corridor and the block boundary, the pins of that block are not checked against the corridor. When used with the *-self* option, the command checks all top-level ports against their associated routing corridors.

The default value of this option is false.

`-shorts true | false`

Checks for shorts that are caused by two pins on the same layer that touch or overlap each other. Pins that are connected to the same net are not considered to be shorted. If this option is not specified, the command performs the shorts check. For ports with multiple-pins/electrically equivalent-pins, each of the pins are checked for violations. And each individual violation is reported in the error-browser GUI. On the command prompt though any combination of two ports that are shorted are reported a single time (independent of the number of violations their individual pins create).

The default is false for this option.

`-self`

Limits the pin placement check to the top-level ports.

`-sides true | false`

Checks for pin side violations that are caused by a pin's placement violating side constraints. The violating side constraint can be any of the following (in order of decreasing priority): individual pin constraints, topological, bundle or block constraints. In the presence of multiple constraints (individual and block constraints for example) the one with the higher priority is given precedence and checked against.

Note that command reports violations and sides with respect to the reference block. The default is false for this option.

`-single_pin connected | unconnected | all`

Checks for unroutable pins on abutted edges. Valid values for this option are:

- *connected*

  A block pin is flagged as a single (unroutable) pin if any one of the following are true:

  - The block pin is placed on a block edge that abuts another block edge and the block cell pin does not abut the other block pin on the same metal layer, or these two pins mismatch in width.

  - The block pin is placed on a block edge that coincides with the top-level cell boundary and connects to anything other than a terminal (top-level pin),

Feedback

unless the pin connects only to other pins on the same block and those pins are stacked on top of the pin.

- The block pin is placed on a block edge that coincides with the top-level cell boundary and the block cell pin is connected only to a terminal, but the terminal is not stacked on top of the block cell pin on the same metal layer, or the terminal and the cell pin mismatch in shapes.

- *unconnected*

  A block cell pin is flagged as a single (unroutable) pin if either one of the following is true:

  - The block cell pin is logically unconnected to any pin or terminal and is placed on a part of the block edge that abuts another block edge.

  - The block cell pin is logically unconnected to any pin or terminal and is placed on a part of the block edge that coincides with the top-level cell boundary.

  When you specify *-single_pin unconnected*, the command also checks terminals. A terminal is flagged if it is logically unconnected and is located on a top-level cell boundary that abuts a macro edge.

- *all*

  A block cell pin is flagged as a single (unroutable) pin if any of the scenarios described for *connected* or *unconnected* occur.

The above checking applies only to pins that are placed on (abutted) edges. For *off-edge pins* that overlap with other physical blocks above/beneath them, the command checks to see if there is a corresponding matching pin above/below it. It also checks to ensure the matching pin is of the same size/shape and layer as the off-edge pin. Off-edge pins that have routing to other terminals are skipped for this type of checking.

When checking for single pins the pin being checked is expected to be of the same type (signal or PG) as its matching/corresponding pin (whether abutted or stacked). Also the abutted pins are expected to be of compatible directions.

For block edges that abut (or overlap in case of parent and child block) hard-macro edges, a pin placed on such an edge is considered legal if it either has a matching hard-macro pin or there is no blockage/routing-shape on the same layer within the abutted hard-macro abutted/adjacent to the port.

Note that *physical-only cells* (such as filter of cap cells) are ignored by the single pin check. For pins abutted to their parent block pins, the single pin check also reports any cases where the child block pin is shorter than the abutted

Feedback

parent block pin. The opposite scenario (that is child block pin is longer) is not considered a violation.

Additionally the *-connection_type* option can be used to filter/restrict reporting/checking of single pin violations to a subset of edge interfaces.

If this option is not specified, the command skips the single pin check.

`-stacking true | false`

Checks if there exist any stacking violations. Whether or not a pin to pin stacking or a pin to power or ground preroute stacking is regarded as a violation is determined by the setting of *-stacking_type* option of command *create_block_pin_constraint*.

`-synthesized_pins true | false`

This check reports and returns all the pins inserted by the tool to avoid single pins, during pin-placement on abutted designs. If this option is not specified, the command skips this check.

The default is false for this option.

`-wire_track true | false`

Determines if pins are centered on wire tracks. A vertical wire track on the same layer as the pin must coincide with the vertical central axis of the pin for pins on a horizontal edge. A horizontal wire track must coincide with the horizontal central axis of a pin on a vertical edge.

Off-edge pins are checked against the wire-track only if the *-off_edge* option is also set to true along with the *-wire_track* option. For an off-edge pin, the command verifies that off-edge pins are centered on wire tracks in the preferred direction of the metal layer of the pins. The pins are not checked against the wire tracks in the nonpreferred direction. If this option is not specified, the command skips the wire track check.

The default is false for this option.

`-wide_track true | false`

Checks that pins satisfy track width constraints. When set to true, the check flags two types of violations: 1) pins that are placed on reserved-for-width tracks, 2) pins whose width is different than the width specified for the track.

The default is false for this option.

`-window_length` *`window_length`*

Specifies the window length to be used during pin-density computation. The value is to be specified in microns, if not specified then the command uses a

Feedback

default value (that is reported on the prompt) for computing the pin density. The default value is a function of site row height.

If the specified window length is less than the default, the tool issues a warning message and uses the default. The default is a multiple of site-row height and is computed based on the design and library technology.

This option can only be used with the *-pin_density_map* option set to true.

`-keep_pins_together true | false`

checks violation of the keep_pins_together bundle constraint. when set to true, it reports Violations in the following cases:

- Any other signal pin (Not PG) lies among the bundle pins on the same layer of bundle pins.
- Empty Tracks between bundle pins more than pin spacing constraints specified.
- If the order in which Bundle pins are placed is different than the Bundle order specified in the constraints.

In case of folding Bundle Pin Placement, if the value of -interleaving_layer_range bundle constraint is set as N. Then the Bundle pins are interleaved on N+1 layers. In that case, All the individual interleaved layers are checked for violations.

The default is false for this option.

`list_of_objects`

Specifies the collection of block cells for pin placement checking. The command checks pin placement only on the blocks you specify. If no blocks are specified, the command checks the pins on all block cells.

Description

This command performs the pin placement check on specified pins or ports of specified cell type (specified by options *-pins*, *-nets*, *-ports*, *-self*, *-cell_type*). If multiple options are specified, the pin placement check is performed on the objects of the common sets, that is, objects met all specified conditions. If none of these options are specified, the pin placement check is performed on all of the block pins whose parent blocks are enabled.

When performing the pin placement checks, this command uses the constraint values set by the commands *set_individual_pin_constraints*, *set_topological_pin_constraints*, *set_bundle_pin_constraints*, or *create_block_pin_constraint* (these constraints can also be set by *read_pin_constraints* using pin constraints file). The command uses default pin constraints if there are no pin constraints applied.

Feedback

If there are no options specified for the types of checks, the command checks only for missing pins, short pins and min spacing (specified by the technology file) violations. By default, the command examines multiple levels of physical hierarchy (MPH support) for pin-constraint checking. The *set_editability* can be used to enable/disable checking on individual reference-blocks or levels of physical hierarchy. Some options have specific behavior relating to how they support disabled blocks. See the description under each option to understand the behavior.

Examples

The following example checks all blocks in the design for shorted and missing pins. It also determines if any two signal pins are closer than the number of wire tracks previously specified by the *-pin_spacing* option of the *create_block_pin_constraint* command.

```
prompt> check_pin_placement -shorts true -missing true -pin_spacing true
```

See Also

- place_pins
- report_block_pin_constraints
- create_block_pin_constraint
- set_editability

---

check_placement_constraints

Checks placement constraints before running *create_placement* or *place_opt*.

Syntax

status *check_placement_constraints*

Description

This command is used to check coarse placement constraints before running *create_placement* or *place_opt*. If any infeasible constraints are found, information about the constraints will be written out for the user to fix.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks placement constraints:

```
prompt> check_placement_constraints
```

Feedback

See Also

- create_placement
- place_opt

---

check_pre_pin_placement

Checks for unfriendly user constraints and design issues that might cause pin placement errors. Run this command before performing pin placement.

Syntax

string *check_pre_pin_placement*

```
[-filename file_name]
[-self]
```

Data Types

file_name	string

Arguments

`-filename` *file_name*

Writes out the placement check results to the specified file name. By default, the command only writes the pin placement check results to the console.

`-self`

When specified, check will be performed on top ports, instead of block pins. to the console.

Description

This command issues a warning message for one the following scenarios:

- The allowed-side constraint conflicts with the allowed-layer constraint.
- A edge of a block does not have tracks overlapping with it.
- An off-edge fixed pin has topological constraints.
- A fixed pin is outside of block boundary.
- Any side of the bbox for a block cannot be touched by the boundary for that block.
- Inconsistent boundary for a same block between design/abstract view and frame view.
- A fixed pin has topological constraints and its parent cell is facing the target cell, however the pin is not facing the target cell.

Feedback

- A fixed pin has blockage, pin guide, route corridor or pin short violations.
- A fixed pin is abutted with another block, and the abutted-edge is close to a pin/routing/metal-blockage. In this situation the abutted pin that is created will overlap with the blockage.
- A topological constraint specifies a path that starts from and ends at the same block, but does not specify which pin the path should start from and end at.
- A topological constraint specifies direct connection between two cells which is impossible in the given floorplan.
- A topological constraint specifies direct connection between a port/pin and its target which is impossible in the given floorplan.
- A topological constraint specifies direct connection between sides for two cells which is impossible in the given floorplan.
- A topological constraint specifies very unfavorable side connection: the sides specified are opposite to the facing edges.
- Two cells can only be connected through other cells, while these other cells are neither allowed for feedthroughs, nor enabled for planning.
- A port/pin can only connect to its target through other cells, while these other cells are neither allowed for feedthroughs, nor enabled for planning.
- Inconsistent blockages across MIBs.
- Range/offset overlap between net/bundle constraints.
- Range/offset overlap between net/bundle constraint and pre-existing fixed pin.
- A net is included in multiple bundles.

Examples

The following command checks the design for possible issues before performing pin placement with the *place_pins* command.

```
prompt> check_pre_pin_placement
```

The following command checks the design for possible pin placement issues and writes out the list of checks performed and results to the file named

```
prompt> check_pre_pin_placement -filename pinplacement.rpt
```

See Also

- place_pins

Feedback

check_pre_place_io

Check design data before IO placement and bump assignment.

Syntax

status *check_pre_place_io*

```
[-io_guides]
[-pad_assignment_file filename]
[-matching_types]
```

Data Types

filename	string

Arguments

`-io_guides`

Check whether there exists any IO guide that cross any block boundary.

`-pad_assignment_file` *filename*

Check whether user pad assignment is correct.

`-matching_types`

Check whether the matching types do not have bumps in blocks, MIB violations, netlist violations, has enough bumps and has unique components. The checking for netlist violations is a step by step procedure. For all violating matching type net violations a specific warning will be issued and the user will also be informed if the matching type has to be removed from the design if it has conflicts with a specific net in the design.

Description

This command check for design data errors before user runs place_io command. It will not change the design data.

Examples

The following example performs design data checking.

```
prompt> check_pre_place_io -io_guides -pad_assignment_file file_name
```

See Also

- place_io

Feedback

check_probes

Check if probes and markers are valid.

Syntax

status *check_probes*

```
[-max_in_group number]
```

Data Types

```
number              integer
```

Arguments

```
-max_in_group number
```

Specifies how frequent a probe should be inserted in the scan chain. The default value is 3.

Description

This command checks if probes and markers in the design are valid. Report any error found. A probe is valid if (1) is on the probe metal layer, and (2) has a corresponding marker, and (3) is connected to SI pin directly. A marker is valid if (1) has a corresponding probe, and (2) on the marker layer, (3) meets width and height requirement. This command also checks if there is at least one probe for every <number> of flops on the scan chain.

Examples

```
prompt> check_probes

prompt> check_probes -max_in_group 5
```

check_pt_qor

Checks PrimeTime QoR such as timing and power.

Syntax

```
status check_pt_qor
-reset

status check_pt_qor
-report_script file_name

status check_pt_qor
[-type  global_timing | summary | max_delay | min_delay
        | max_transition | max_capacitance | power | noise]
```

Feedback

Feedback

```
paths_per_endpoint          integer
max_path_count              integer
group_name                  list
minimum_slack               float
maximum_slack               float
format                      string
digits                      integer
```

Arguments

`-reset`

Specifies to terminate current PrimeTime session.

`-report_script` *`file_name`*

Specifies a TCL script file to customize the reporting. when -report_script is specified, the -type and related options are all ignored.

`-type global_timing | scenario_timing | summary | max_delay | min_delay | max_transition | max_capacitance | power`

Specifies the type of QoR to check. The global_timing type is similar to reporting global timing in PrimeTime. The scenario_timing will report merged QoR and QoR for every scenario. The summary type is similar to reporting QoR summary. The max_delay and min_delay types are similar to the *report_timing* command reporting. The max_transition and max_capacitance types are similar to the *report_constraint* command reporting. The power type is similar to reporting power.

`-pba_mode none | path | exhaustive`

Specifies one of the following path-based timing analysis modes:

- *none* (the default) - Disables path-based analysis and enables ordinary graph-based analysis. This is the fastest mode.
- *path* - Performs path-based analysis on paths after they have been gathered by graph-based analysis, producing more accurate timing results for those paths. To control the ordering of the paths (either by original graph-based slack or recalculated path-based slack), set the *pba_path_mode_sort_by_gba_slack* variable.
- *exhaustive* - Performs an exhaustive path-based analysis to determine the truly worst-case paths in the design. This is the most accurate and most computation-intensive mode.

`-group` *`group_name`*

Specifies a group of timing paths for timing and nets or cells for power.

Feedback

Options only available for the *max_delay* and *min_delay* types

-from *from_list*

Reports only paths that start from the specified list of pins, ports, nets, or cell instances; or from startpoints clocked by the named clocks. Valid startpoints are clock pins of sequential devices and input pins of the design.

-rise_from *rise_from_list*

Same as the *-from* option, except that the path must start with a rising transition.

-fall_from *fall_from_list*

Same as the *-rise_from* option, except that the path must start with a falling transition.

-to *to_list*

Reports only paths that end at the specified list of pins, ports, nets, or cell instances; or at endpoints clocked by the named clocks. Valid endpoints are data input pins of sequential devices and output pins of the design.

-rise_to *rise_to_list*

Same as the *-to* option, except that the path data must end with a rising transition.

-fall_to *fall_to_list*

Same as the *-rise_to* option, except that the path data must end with a falling transition.

-through *through_list*

Reports only paths in which the data goes through the named pins, ports, cell instances, or nets. You can use this option multiple times in a command.

-rise_through *rise_through_list*

Same as the *-through* option, except that it applies only to paths with a rising transition at the specified objects.

-fall_through *fall_through_list*

Same as the *-through* option, except that it applies only to paths with a falling transition at the specified objects.

-exclude *exclude_list*

Excludes all paths in which the data goes from, through, or to the specified list of pins, ports, nets, or cell instances.

Feedback

-rise_exclude *rise_exclude_list*

Same as the *-exclude* option, but applies only to rising transitions at the named pins, ports, nets, or cell instances.

-fall_exclude *fall_exclude_list*

Same as the *-exclude* option, but applies only to rising transitions at the named objects.

-nworst *paths_per_endpoint*

Reports up to the specified number of worst paths per endpoint. The default is 1. A larger value results in a larger report and more runtime.

-max_paths *max_path_count*

Reports up to the specified maximum total number of paths among all path groups. The default is equal to the *-nworst* setting, or 1 if the *-nworst* option is not used.

-unique_pins

Reports only the single worst timing path through any given sequence of pins. No other paths are reported for the same sequence of pins from startpoint to endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin sequence, then paths starting with a falling edge are not reported for that sequence of pins.

-slack_greater_than *minimum_slack*

Reports only paths with slack greater than the specified *minimum_slack* value; these paths have a negative slack better than the specified *minimum_slack* value (or a positive slack that is farther from causing a violation). This option is intended to be used with the *-slack_lesser_than* option to report paths within a specific range of slack.

-slack_lesser_than *maximum_slack*

Reports only paths with slack less than the specified *maximum_slack* value; these paths have a negative slack worse than the specified *maximum_slack* value (or a positive slack that is closer to causing a violation).

-include_hierarchical_pins

Causes the timing path report to show points for the hierarchical pins crossed, as well as all leaf pins in the path. The hierarchical pins are shown only for documentation purposes; they are reported as having zero incremental delay and do not affect the timing results.

Feedback

-start_end_pair

Reports the worst path for each startpoint-endpoint pair in the design, including all violating startpoint-endpoint pairs by default, or all startpoint-endpoint pairs with slack worse than the value specified by the *-slack_lesser_than* option if that option is used.

-path_type *format*

Specifies the types of path information displayed in the timing report, using one of the following format keywords:

- *summary* -- Displays the path startpoint, path endpoint, and slack.
- *end* -- Displays the path endpoint, path delay, required time, and slack.
- *short* -- Displays a report like the default *full* report but omits the intermediate points between the startpoint and endpoint.
- *full* (the default) -- Displays the full data path, including all intermediate points and their incremental and cumulative delay, together with the launch and capture clock arrival times, data required time, and slack.
- *full_clock* -- Displays a *full* report with the addition of the clock path points from the clock source to the launch and capture points.
- *full_clock_expanded* -- Displays a *full_clock* report with the addition of the clock path points between the primary clock source and its related generated clock source point. This report is different from a *full_clock* report only when the clock is a generated clock.

-input_pins

Shows cell input pins as well as cell output pins in the timing path. As a result, the report shows the incremental net and cell delays separately at each point, instead of combined. By default, the report shows only the cell output pins.

-nets

Shows nets in the timing path. By default, the report does not show nets.

-nosplit

Prevents line splitting. This can useful for scripts that extract information from the report. By default, the report generates a new line when the text cannot fit in the alloted space in a column.

-transition_time

Shows the transition time (slew) in the path report for each driver pin and load pin, appearing as an additional column labeled "Trans".

Feedback

-capacitance

Shows the total capacitance in the path report for each net, appearing as an additional column labeled "Cap".

-significant_digits *digits*

Specifies the number of digits after the decimal point displayed for time values in the generated report.

-crosstalk_delta

Reports crosstalk delta delay values at cell input pins in a column labeled "Delta". The *-input_pins* option is automatically selected. The delta values are computed during crosstalk signal integrity analysis.

-derate

Shows derating factors in a column labeled "Derate".

-variation

Includes parametric on-chip variation (POCV) information in the report in columns labeled "Mean" and "Sensit" if POCV analysis is enabled in PrimeTime.

-exceptions dominant | overridden | all

Reports user-specified timing exceptions that are satisfied per timing path being reported.

Specifying dominant reports the dominant timing exception in the path. It can be one of the following: false path, minimum and maximum delays, and multicycle paths.

Specifying overridden reports all the timing exceptions that were overridden by the dominant timing exception.

-voltage

Reports the operating voltage for each path element in a column labeled "Voltage", allowing you to debug voltage levels in multivoltage designs.

Options only available for the *noise* type

-verbose

Reports noise details such as aggressor bump height, width and slack. This option works only with the noise type.

-save_session

Specifies the directory to save PrimeTime session.

Feedback

Description

When your design is optimized with PrimeTime ECO using the *fix_pt_eco* command, you may want to check QoR in PrimeTime timing values. Use the *check_pt_qor* command to view PrimeTime timing values. The *check_pt_qor* command checks PrimeTime's timing, DRC, and power, and shows their values. By default, the command reports top level timing summary with setup and hold WNS, TNS, and violation count. It is as same as specifying the *-type global_timing*. When the summary type is specified, the command reports QoR summary including setup, hold, max transition, and max capacitance violations. When the max_transition or max_capacitance type is specified, the command reports pins with negative slacks. When the max_delay or min_delay type is specified, the command reports the timing path with its slack values.

When you specify the power type, the command shows leakage, dynamic and total powers in all scenarios.

If you want to customize the reporing, specifify -report_script, which is mutually exclusive with -type.

If you need to terminate PrimeTime, specify the *-reset* option. If the *-reset* option is specified, other options are ignored.

Examples

Without any options, it shows global setup and hold timing summary, which is similar to PrimeTime's *report_global_timing* command.

```
prompt> check_pt_qor
```

You can view max or min delay timing path in PrimeTime timing by using the -type max_delay or -type min_delay option, which is similar to PrimeTime's report_timing command.

```
prompt> check_pt_qor -type max_delay
```

You can use standard reporting options like -from, -to, -through, etc to specify the timing path that you are interested in.

```
prompt> check_pt_qor -type max_delay -from U1/CK -to U2/D
```

The example below shows max_transition violations.

```
prompt> check_pt_qor -type max_transition
```

For QoR summary, use the -type summary option, which is similar to PrimeTime's report_qor command.

```
prompt> check_pt_qor -type summary
```

For PrimeTime PX power reporting, the -type power option is used as shown below.

Feedback

```
prompt> check_pt_qor -type power
```

- report_starrc_options
- eco_opt

---

check_rdl_routes

Check RDL router shapes.

Syntax

status *check_rdl_routes*

```
[-layers layer_list]
[-nets collection_of_nets | -nets_in_file nets_file]
[-objects collection_of_objects]
[-coordinates bbox_list]
[-honor_user_constraint_rules true|false]
[-check_min_width_on_edges true|false]
[-check_window_density_mode all|max|min|none]
```

Data Types

layer_list	collection
collection_of_nets	collection
nets_file	string
collection_of_objects	collection
bbox_list	list

Arguments

`-layers` *layer_list*

Specifies the target RDL layers for checking by the names from the technology file.

`-nets` *collection_of_nets*

Specifies the nets to check.

`-nets_in_file` *nets_file*

Specifies the name of the file that contains the list of nets to check.

Feedback

-nets has higher priority than *-nets_in_file*.

`-objects` *`collection_of_objects`*

Specifies the nets (see *-nets*) by cells or pins. Only the sub-nets which involve the cells or pins are affected.

If neither *-nets*, *-nets_in_file*, nor *-objects* option is specified, all nets are checked.

`-coordinates` *`bbox_list`*

Specifies the regions of checking for speeding up the checking process. The regions are applied to all RDL layers. If any input regions overlapped, then they are merged into a larger region.

`-honor_user_constraint_rules` *`true|false`*

Specifies whether to honor user constraint rules. The default value is false. The user constraint rules include NDR rules, and app options. If it is false, only tech rules are checked.

`-check_min_width_on_edges`

Specifies whether to check the minWidth rule on shape edges. The default value is false. By default, min width is checked by the shape width attribute. If the option is set as true, then the min width is checked by the shape edges. For example, if there is a shape path with width equals to minWidth and octagon end caps, then with the option off, there is no minWidth violation reported. But with this option on, the octagon end cap parts are marked as violation.

`-check_window_density_mode`

Specifies whether to check the window density. The default value is none. By default, neither min nor max window density is checked. If the option is set as max or min, then max or min window density is checked, respectively. If the option is set as all, then both max and min window density are checked.

Description

This command checks RDL net shapes,

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks the flip-chip nets specified in the RDLNetFile.

```
prompt> check_rdl_routes -nets_in_file RDLNetFile
```

The following example checks all flip-chip nets on layer M9.

Feedback

```
prompt> check_rdl_routes -layers M9
```

See Also

- route_rdl_flip_chip

- optimize_rdl_routes
- push_rdl_routes
- remove_routes

---

check_routability

Checks for many known issues that degrade the performance or quality of routing commands. These checks also include some sanity checks of the input data.

Syntax

status *check_routability*

```
[-access_edge_whole_side true | false]
[-allow_via_rotation true | false]
[-blocked_range integer]
[-blocked_range_via_side integer]
[-check_congestion_map_overflow integer]
[-check_frozen_net_blocked_ports true | false]
[-check_lib_via_cut_blockage true | false]
[-check_min_grid true | false]
[-check_no_net_pins true | false]
[-check_non_standard_cell_blocked_ports true | false]
[-check_out_of_boundary true | false]
[-check_pg_blocked_ports true | false]
[-check_real_metal_blockage_overlap_pin true | false]
[-check_redundant_pg_shapes true | false]
[-check_routing_track_space true | false]
[-check_shield true | false]
[-check_standard_cell_blocked_ports true | false]
[-check_via_cut_blockage true | false]
[-connect_standard_cells_within_pins true | false]
[-error_data errdata_name]
[-honor_layer_constraints true | false]
[-obey_access_edges true | false]
[-obey_direction_preference true | false]
[-report_no_access_edge true | false]
[-standard_cell_search_range integer]
[-via_ladder true | false]
[-max_error integer]
```

Feedback

Data Types

```
integer       integer
errdata_name  string
```

Arguments

`-access_edge_whole_side true | false`

Controls the access points when access edges are obeyed (*-obey_access_edges true*).

An access edge is marked by a narrow rectangle, a short line, or a single point. The access edge mark either fully or partially overlaps one of the port edges. When the overlap is not full, such as when the access edge mark is a single point, there are two possible interpretations of the connection rule.

By default (*true*), the connection can be made to any point on the marked port edge. If set to *false*, the connection must be made to the exact access edge mark.

`-allow_via_rotation true | false`

Controls whether the tool can use rotated vias at pin connections.

By default (*true*), rotated vias will follow the app option setting *route.common.rotate_default_vias*.

`-blocked_range` *integer*

Specifies the number of pitches for the same-layer accessibility check for macro and top-level ports.

The default is 10.

`-blocked_range_via_side` *integer*

Specifies the number of pitches for the accessibility check on the other side of an access via.

The default is 10.

This check applies only to macro and top-level ports.

`-check_congestion_map_overflow` *integer*

Checks global route congestion map overflow can be greater than or equal to the given value. This check runs a fast global route to get a coarse result. Run the report_congestion command when you need an accurate congestion map.

The range of values is 0 to 100. The default value is 0. When the given value is 0, this check is disabled.

Feedback

`-check_frozen_net_blocked_ports true | false`

Controls whether the command checks for blocked frozen net ports.

By default (*false*), the command does not check frozen net ports.

`-check_lib_via_cut_blockage true | false`

Controls whether the command checks for incorrect real metal via cut blockages in the reference libraries.

A via cut blockage is treated as a piece of real metal if all of the following attributes are *false*:

- *icc_route_guide* • *icc_system_layer_blockage* • *is_design_rule_blockage* • *is_boundary_blockage* • *is_external_boundary_blockage* • *is_zero_spacing*

When the size of a via cut blockage does not fit a legal cut size (cutWidthTbl, cutHeightTbl, minWidth) specified for the layer in the technology file, it is an incorrect real metal via cut.

In general, the attributes except *is_zero_spacing* are special attributes that are generated from the tool flow. You can set the *is_zero_spacing* attribute to *true* to represent a routing blockage or to *false* to represent a real metal blockage.

An incorrect real metal via cut blockage degrades the routing performance and DRC convergence.

By default (*false*), the command does not check for incorrect real metal via cut blockages in the reference libraries.

`-check_min_grid true | false`

Controls whether the command checks and reports design objects that are not on the user (manufacturing) minimum grid.

By default (*true*), the command performs the minimum-grid checks.

`-check_no_net_pins true | false`

Controls whether the command checks the accessibility for pins without an assigned net.

By default (*false*), the command does not check pins without nets.

`-check_non_standard_cell_blocked_ports true | false`

Controls whether the command checks for blocked macro, top-level, and non-standard-cell ports.

By default (*true*), the macro, top-level, and non-standard-cell ports are checked.

Feedback

`-check_out_of_boundary true | false`

Controls whether the command checks and reports the pins that are outside of the design boundary. The design boundary is the same as the die size.

By default (*true*), the command performs the out-of-boundary checks.

`-check_pg_blocked_ports true | false`

Controls whether the command checks for blocked power and ground ports.

By default (*false*), the command does not check the power and ground ports.

`-check_real_metal_blockage_overlap_pin true | false`

Controls whether the command checks for real metal routing blockages that touch or overlap a pin inside the reference libraries.

A routing blockage is treated as a piece of real metal when all of the following attributes are *false*:

- *icc_route_guide* • *icc_system_layer_blockage* • *is_design_rule_blockage* • *is_boundary_blockage* • *is_external_boundary_blockage* • *is_zero_spacing*

In general, the attributes except *is_zero_spacing* are special attributes that are generated from the tool flow. You can set the *is_zero_spacing* attribute to *true* to represent a routing blockage or to *false* to represent a real metal blockage.

By default (*false*), the command does not check for real metal routing blockages that touch or overlap a pin inside the reference libraries.

When *true*, the command issues a warning message to inform you to review the blockage's attributes.

`-check_redundant_pg_shapes true | false`

Controls whether the command checks for redundant power and ground shapes that overlap at the same location.

By default (*true*), the command checks for duplicated redundant power and ground shapes.

`-check_routing_track_space true | false`

Controls whether the command checks for power and ground (PG) via obstacles in the space around each routing track by using the default or nondefault spacing requirement.

By default (*false*), the command does not check for PG via obstacles in the space around each routing track.

Feedback

When *true*, the command issues a warning message to inform you that these PG vias might degrade the routing quality. The command checks only the PG vias.

`-check_shield true | false`

Controls whether the command performs checks on the routing shapes related to the shielding flow.

By default (*true*), the command checks the attributes of the routing and shield shapes for known problems in the shielding flow. It does not check the correctness of the shield shapes.

There are three shielding-related checks:

- Non-PG net shape with a *shape_use* attribute of *shield_route*.

  Only PG net shapes can have a *shape_use* attribute of *shield_route*.

- Long PG net wire with a *shape_use* attribute of *detail_route*.

  In general, a PG wire with a *shape_use* attribute of *detail_route* is a tie-off wire. A very long PG wire could be a part of a PG mesh or rail.

- Net with a shield nondefault rule that has a shape whose *shape_use* attribute is not *detail_route*.

For all Zroute commands except *check_routability*, you can disable the shield data checker by setting the *route.common.check_shield* application option to *true*.

`-check_standard_cell_blocked_ports true | false`

Controls whether the command checks for blocked standard cell ports.

By default (*true*), the standard cell ports are checked.

`-check_via_cut_blockage true | false`

Controls whether the command checks for incorrect real metal via cut blockages in the design.

A via cut blockage is treated as a piece of real metal if all of the following attributes are *false*:

- *icc_route_guide* • *icc_system_layer_blockage* • *is_design_rule_blockage* • *is_boundary_blockage* • *is_external_boundary_blockage* • *is_zero_spacing*

When the size of a via cut blockage does not fit a legal cut size (cutWidthTbl, cutHeightTbl, minWidth) specified for the layer in the technology file, it is an incorrect real metal via cut.

Feedback

In general, the attributes except *is_zero_spacing* are special attributes that are generated from the tool flow. You can set the *is_zero_spacing* attribute to *true* to represent a routing blockage or to *false* to represent a real metal blockage.

An incorrect real metal via cut blockage degrades the routing performance and DRC convergence.

By default (*true*), the command checks for incorrect real metal via cut blockages in the design.

`-connect_standard_cells_within_pins true | false`

Controls whether via connections to standard cell pins must be fully inside the pins.

By default (*false*), the via connections do not need to be fully inside the pins.

`-error_data` *`errdata_name`*

Specifies the name of the generated error data file.

The default is *check_routability*.err.

If the specified error data file already exists, the command overwrites it.

`-honor_layer_constraints true | false`

Controls whether the command considers the layer constraints when checking the accessibility of ports and the connectivity of nets.

The layer constraints include the global minimum and maximum routing layer constraints set by the *-min_routing_layer* and *-max_routing_layer* options of the *set_ignored_layers* command; the net-specific minimum and maximum routing layer constraints set by the *-min_routing_layer* and *-max_routing_layer* options of the *set_routing_rule* command; and the freeze layer constraints set by the *route.common.freeze_layer_by_layer_name* and *route.common.freeze_via_to_frozen_layer_by_layer_name* options of the *set_app_options* command.

By default (*true*), the command considers the layer constraints when checking for blocked ports and nets.

`-obey_access_edges true | false`

Controls whether pins can be connected only at their access edges.

By default (*false*), pins can be connected at any point.

`-obey_direction_preference true | false`

Controls whether only preferred direction access is allowed.

Feedback

By default (*false*), access is allowed in both the horizontal and vertical directions. When set to *true*, access is allowed only in the preferred direction.

This option applies only to non-standard-cell ports. Standard-cell ports are usually accessed only by vias. When a wire on the port layer is needed, it can be in any direction.

`-report_no_access_edge true | false`

Controls whether the command reports the unconnected pins without predefined access edges.

By default (*false*), pins without access edges are not reported.

`-standard_cell_search_range` *`integer`*

Specifies the number of pitches for the same-layer accessibility search of standard cell pins.

The default is 2.

`-via_ladder true | false`

Controls whether the command performs the via ladder flow sanity checks.

By default (*false*), the command does not perform the via ladder flow sanity checks. When *true*, the command will check whether the option setting for via ladder flow is correct and check whether tracks are on the center of via_ladder pin.

`-max_error` *`integer`*

Specifies the maximum number of DRCs detected.

If this option is set to a non-negative value, it will skip reporting violations when DRCs exceeds the value.

Description

The *check_routability* command checks many issues known to degrade the routing performance or quality, including identification of blocked ports, out-of-boundary ports, minimum manufacturing grid violations, off-routing-track ports, and many miscellaneous sanity checks for routing objects. The command reports the results as part of the standard output and in an error data file. You can display the error data file in the GUI error browser. Some reports are available only in the standard text output and not in the GUI.

The *check_routability* command does not check the routing design rules. To check the routing design rules, use the *check_routes* command.

Most of the issues reported by the *check_routability* command are warnings. Review the generated report to verify that these suspicious issues are intended.

Feedback

Issues reported as errors should be corrected before running any routing commands.

For legacy reasons, note that some "off-grid" messages mean "off-routing-track".

A logical port can have several physical pins. A port is considered blocked if none of its pins is accessible.

A top-level or macro pin is considered accessible if a legal path can be extended from the pin to a certain distance around it. This path can be on the pin layer or can extend to a neighboring layer by a single via. The required distance on the pin layer and on the layer at the other side of the via are set by the *-blocked_range* and *-blocked_range_via_side* options.

A standard cell pin is considered accessible if there is a legal path that extends to the next layer or a path on the pin layer that extends to the distance set by the *-standard_cell_search_range* option or a shorter path on the pin layer ended by a via to a neighboring layer.

- You can fix blocked ports by removing or modifying the blockages, by moving or modifying the ports, or by modifying the netlist.
- You can fix out-of-boundary ports by moving them or, if appropriate, by fully removing them.
- You can either fix minimum-grid violations or intentionally accept them.

You can run the *check_routability* command at any stage of the routing flow. However, it is most useful when run before global routing. It can be useful to run the command after routing to identify the root cause of certain routing failures.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following command performs accessibility checks, out-of-boundary checks, and minimum-grid checks. You should run it before global routing and, if needed, modify the design according to the generated report.

```
prompt> check_routability
```

The command writes a report to the standard output. The report includes either "no violation" messages or a detailed list of the violations. The following example shows a report for a design with violations:

```
****************************************
==     Check for min-grid violations      ==
****************************************

  ***** Technology min-grid violations *****
```

Feedback

```
  >>> Y minimum grid violation in contact cut via2 20.5544 on layer V2.

  >>>> Found 1 Technology min-grid violations

  ====== Library  min-grid violations ======

  >>> Y minimum grid violation for boundary of library cell AND2X4 at
     (0.0000 -0.0230)_(0.3440 -0.0230).
  >>>> Found 1 Library min-grid violations

  ======= Design min-grid violations =======

   ports isolated by layer constraints and the shapes on freeze layer
   can't be accessed.

>>>>>> The design cannot be cleanly routed because it has 2 blocked Nets
```

Feedback

The following command performs only out-of-boundary and minimum-grid checks:

```
prompt> check_routability \\
   -check_standard_cell_blocked_ports false \\
   -check_non_standard_cell_blocked_ports false
```

The following command does not report minimum-grid violations:

```
prompt> check_routability -check_min_grid false
```

The following command only reports the first 20 DRC violations:

```
prompt> check_routability -max_error 20
```

---

check_routes

Verifies and reports routing design rule checking (DRC) violations, net opens, antenna rule violations, voltage-area rule violations, and via conversion rates. DRCs, antenna violations and voltage-area rule violations can be viewed in error browser. Open net information cannot be seen in error browser.

Syntax

status *check_routes*

```
[-nets collection_of_nets]
[-open_net true | false]
[-report_all_open_nets true | false]
[-drc true | false]
[-antenna true | false]
[-voltage_area true | false]
[-check_from_user_shapes true | false]
```

Feedback

```
[-check_from_frozen_shapes true | false]
[-coordinates list_of_regions]
[-write_blockage_drcs_to_error_cell_as_ignored true | false]
```

Data Types

collection_of_nets	collection
list_of_regions	list

Arguments

`-nets {`*collection_of_nets*`}`

Specifies the nets to check.

If you use this option, the command checks only for open nets (*-open_net* option), antenna violations (*-antenna* option), and voltage-area violations (*-voltage_area* option) of the specified nets. All other options are ignored.

By default, all nets are verified.

`-open_net true | false`

Controls whether the command checks for open nets in the block.

By default (*true*), the command checks for open nets.

`-report_all_open_nets true | false`

Controls whether the command reports all violations when checking open nets.

By default (*false*), the command reports a maximum of 200 open net violations.

`-drc true | false`

Controls whether the command checks for design rule violations on the specified nets.

By default (*true*), the command checks for design rule violations.

`-antenna true | false`

Controls whether the command checks for charge-collecting antenna rule violations on the specified nets.

By default (*true*), the command checks for charge-collecting antenna rule violations. Antenna checking requires antenna rules to be defined in the cell library. If no antenna rules are defined, the command skips this check regardless of this option setting.

When a port has multiple physical pins and routing shapes connect to one of the pins to cause antenna violations, antenna violations are not reported on all of those pins of the port by default. To report violations on all of those pins, use options "-check_from_user_shapes" or "check_from_frozen_shapes".

Feedback

`-voltage_area true | false`

Controls whether the command checks for voltage-area rule violations on the specified nets.

By default (*true*), the command checks for voltage-area rule violations.

`-check_from_user_shapes true | false`

Controls whether the command includes user-created shapes in the checks.

By default (*false*), user-created shapes are not included in the checks. But via coloring-related DRCs do not get affected by this option. The command by default reports via coloring-related DRC even for user-created shapes.

`-check_from_frozen_shapes true | false`

Controls whether the command includes frozen shapes in the checks.

Frozen shapes include shapes on frozen layers and shapes of frozen nets.

- A layer is frozen when the *route.common.freeze_layer_by_layer_name* application is set to *true* for the layer.
- A net is frozen when its *physical_status* attribute is set to *locked*. However, the command treats shapes on frozen PG nets that do not have a type of stripe or ring as not-fixed. Shapes on signal nets and of user-route type are treated as fixed if option 'check_from_user_shapes' is set to false.

To include reporting DRC of frozen shapes with attribute locked, additionally set the below app option to *true*. • *route.detail.check_routes_frozen_mode_include_shape_with_attribute_locked*

By default (*false*), frozen shapes are not included in the checks.

`-coordinates list_of_regions`

Specifies the rectangular or rectilinear regions in which to perform design rule checking.

Each rectangular region is specified by its lower-left and upper-right coordinates:

`{llx lly} {urx ury}).`

Each rectilinear region is specified by its boundary points:

`{x y} {x y} {x y} {x y} ... )`

The coordinate unit is microns. Each region defines a target area for design rule checking. The specified regions can overlap or be disjoint. If you specify more than one area, the command checks the union of all specified areas.

Feedback

In addition, the command might flag some DRC violations in the neighborhood of the specified regions.

When you specify this option, the following net-based design rules are not checked:

- Open net
- Antenna
- Voltage area
- Tied to rail and tied to rail directly
- Direct connection of secondary power and ground pins and maximum connections for secondary power and ground pins
- Direct connection of comb routing, maximum connections for comb routing, and daisy-chain distance for comb routing

In addition, when you use this option, the command does not report wire length, via count, and redundant via insertion rate.

You cannot use the following net-related options with the *-coordinates* option: *-nets*, *-open_net*, *-voltage_area*, *-report_all_open_nets*, and *-antenna*.

If you do not specify this option, the command checks the entire block.

`-write_blockage_drcs_to_error_cell_as_ignored true | false`

Controls whether to write DRCs involving routing blockages to DRC error cell that are later displayed in error browser.

By default, all DRCs are displayed in error browser. Setting this option skips the display of DRCs involving routing blockages in error browser.

Description

Verifies, checks, and reports routing statistics for a block. The statistics are based only on the signal routes; PG routes are not included. To report routing statistics that include PG routes, use the *report_design* command.

The *check_routes* command reports the following information for a routed design:

- Open nets
- DRC violations
- Charge-collecting antenna violations

  Antenna analysis is performed only if antenna rules are defined in the cell library.
- Voltage-area violations

Feedback

- Wire length

  The command reports the total wire length, the total routed wire length, and the wire length per layer.

- Contacts

  The command reports the total number of contacts, the total number of routed contacts, and the number of instances of each via master.

- Wires

  The command reports both the total number of wires and the total number of routed wires.

- Point connections (PtConns)

  A point connection is a wire that has only one connection one each end.

- Redundant via conversion rate

  The command reports the following types of redundant via rates:

  - Total optimized via conversion rate

    The total optimized via conversion rate is computed as

    ```
    optimized_via_count / total_number_of_vias
    ```

    The optimized via count includes both double vias and DFM-friendly bar vias.

    The total number of vias (Total Number of Contacts in the generated report) includes both fixed and routed vias. Fixed vias are vias that the router cannot optimize, such as vias at the preroute stage or vias that have a *route_type* attribute of *user_enter*. Routed vias are vias that were routed by the router and can be optimized.

  - Total double via conversion rate

    The total double via conversion rate is computed as

    ```
    double_via_count / total_number_of_vias
    ```

    The double via count includes only the double vias.

  - Optimized via conversion rate based on total routed via count

    The optimized via conversion rate based on total routed via count is computed as

Feedback

```
optimized_via_count / number_of_routed_vias
```

The number of routed vias (Total Number of Routed Contacts in the generated report) includes only the routed vias.

Note that the via conversion rates reported by the *check_routes* command do not include PG vias. To report the double via conversion rates that include PG vias, use the *report_design -routing* command.

If you specify the *-nets* option, the *check_routes* command checks only for open nets, antenna violations, and voltage-area violations of the specified nets. It does not check for DRC violations, regardless of the setting of the *-drc* option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example reports DRC violations, open nets, antenna violations, and voltage-area violations for all nets in the block.

```
prompt> check_routes
```

The following example checks for open nets, antenna violations, and voltage-area violations, but not for DRC violations.

```
prompt> check_routes -drc false
```

The following example checks for open nets, antenna violations, and voltage-area violations for the N1, N2, and N3 nets. Note that these rules are checked by default, and DRC violations are not checked.

```
prompt> check_routes -nets {N1 N2 N3}
```

The following example reports only antenna and voltage-area violations for the N1 and N2 nets.

```
prompt> check_routes -nets {N1 N2} -open_net false
```

---

check_routing_corridors

Checks that all shapes are connected for each routing corridor, and that each corridor contains the pins that connect to the nets associated with the corridor.

Feedback

Syntax

status *check_routing_corridors*

routing_corridor

Data Types

routing_corridor string

Arguments

routing_corridor

Specifies the name of the routing corridor to be checked. This is a required option. You can specify only one corridor.

Description

This command checks the specified routing corridor for the following properties:

- The shapes that make up the routing corridor are connected
- All pins of the nets associated with the corridor are covered by the routing corridor shapes

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks the routing corridor associated with the n7 net.

```
prompt> check_routing_corridors [get_routing_corridors -of_objects
 [get_nets {n7}]]
Error: Regions in routing corridor 'RC_0' are not connected. (NDMUI-102)
Error: Routing corridor 'RC_0' does not cover pin 'alu/U332/A2'.
 (NDMUI-103)
1
```

See Also

- create_routing_corridor
- create_routing_corridor_shape
- remove_from_routing_corridor

Feedback

- remove_routing_corridors
- report_routing_corridors

check_rp_constraints

Checks relative placement constraints of the specified relative placement groups and reports possible issues, which could lead to critical or non-critical failure.

Syntax

```
collection check_rp_constraints
[rp_group_list]
[-verbose]
[-analyze_placement]
[-region { {llx lly} {urx ury} }]
[-trials number_of_trials]
[-no_pdc]
[-no_adv]
[-threshold threshold]
[-no_rp_constraints]
[-analyze_libs]
```

Data Types

```
rp_group_list       collection
llx                       float
lly                       float
urx                       float
ury                       float
number_of_trials          integer
threshold                 float
```

Arguments

rp_group_list

Specifies the relative placement groups that will be checked. If no any input is provided then all relative placement groups will be checked.

-verbose

Specifies to report exact location of the failures in relative placement group.

-analyze_placement

Specifies that placement analysis will be performed on the relative placement groups. When this option is specified, the other relative placement constraints will not be checked.

Feedback

`-region { {llx lly} {urx ury} }`

Specifies the boundary of the region where placement analysis is to be performed. A relative placement group will be considered legal for the sites in this region only if it is placed completely within the region. For an anchored relative placement group, this option will be ignored. This option can be used only along with *-analyze_placement* option.

`-trials number_of_trials`

Specifies the number of random sites where the placement of relative placement group will be checked. The default value is 100. A value of 0 will force the placement analysis to be performed on all compatible sites. This option can be used only along with *-analyze_placement* option.

`-no_pdc`

Specifies that no PDC checks are to be performed while doing placement analysis. This option can be used only along with *-analyze_placement* option.

`-no_adv`

Specifies that no advance rule checks are to be performed while doing placement analysis. This option can be used only along with *-analyze_placement* option.

`-threshold threshold`

Specifies the threshold pass rate. Relative placement groups with pass rate below the specified threshold value will be reported. This option can be used only along with *-analyze_placement* option.

`-no_rp_constraints`

When this option is specified, tool will only check if the relative placement group has been successfully placed. The relative placement constraints such as row alignment, column alignment, utilization will not be checked. This option can be used only along with *-analyze_placement* option.

`-analyze_libs`

When this option is specified, tool will analyze the library cells in the design. A cummulative report will be printed after analyzing the library cells.

Description

The *check_rp_constraints* command checks relative placement constraints of the specified relative placement groups for possible issues, which could lead to critical or non-critical failures.

Feedback

The command returns a collection containing the relative placement groups having possible constraint failures. If no constraint failures are seen then an empty string is returned.

When *-analyze_placement* option is provided, the placement analysis of the specified relative placement groups will be performed. For each relative placement group, placement analysis will be done at the random free sites chosen from specified region. For an anchored relative placement group, the placement analysis would be done only at the specified anchor location. The pass rate for a relative placement group is defined as the number of sites at which it could be placed successfully divided by number of free sites at which placement analysis was tried. By default pass rate for all groups is reported, but user could specify threshold to report groups for which pass rate is below threshold. The command returns the collection of reported relative placement groups.

When *-analyze_libs* option is provided, analysis of the library cells associated with the relative placement groups and their available alternatives in the design, belonging to similar family will be performed. The analysis constitues of allowed orients on library cells, available physical variants, library cells with same area, and same pin location.

Examples

The following examples use *check_rp_constraints* to report constraint failures:

```
prompt> check_rp_constraints rp_volt1

****************************************************************************
*******
Report : Relative Placement Summary
Total number of specified top level relative placement groups: 1

check_sadp_tracks

Checks the tracks in the design based on self-aligned double patterning (SADP) track rules.

Syntax

status *check_sadp_tracks*

Arguments

The *check_sadp_tracks* command takes no arguments.

Description

This command checks the self-aligned double patterning (SADP) tracks in the current block. The command checks for conflicts within each SADP track set and between different SADP tracks:

- Two tracks should not overlap exactly.
- Spacing between adjacent tracks must be sufficient to ensure SADP rule compliance.

Examples

The following example checks the SADP tracks in the current block.

```
prompt> check_sadp_tracks
Total Errors = 0
```

See Also

- create_sadp_track_rule
- generate_sadp_tracks
- remove_sadp_track_rule
- report_sadp_track_rule

check_safety_intent

Detects whether the design contains specific types of functional safety intent.

Syntax

string *check_safety_intent*

Feedback

```
[-verbose]
```

Arguments

`-verbose`

Reports the detected types of functional safety intent.

Description

This command tells whether any functional safety intent (that is safety_register_rules, safety_register_groups, repelling_group_bounds) is defined in the current block. When the current block contains such functional safety intent, the returned value is "1". If no such intent is found, the returned value is "0".

This command helps you to provide a unified flow-script for both designs with functional safety intent as well as designs without it.

Examples

The following is an example of the textual report generated by *check_safety_intent -verbose*:

```
prompt> check_safety_intent

Information: Block ChipTop contains FuSa intent (repelling group bounds).
 (SR-009)
1
prompt>
```

See Also

- report_safety_status
- report_safety_register_rules
- report_safety_register_groups

---

check_scan_chain

Allows scan chain structural consistency checking based on the scan chain information stored in the current design.

Syntax

status *check_scan_chain*

```
[-chain_name chain_name]
```

Data Types

chain_name string

Feedback

Arguments

`-chain_name` *chain_name*

Displays detailed information about the structural checking of the specified scan chain, including location of inconsistency.

Description

This command performs a scan chain structural checking based on the scan chain information stored in the current CEL. If the scan chain passes all the structural checks, then the scan chain status is "VALIDATED"/V and the chain can be physically design-for-test (DFT) optimized. If the scan chain fails the structural checks then the scan chain status is "FAILED"/F and the chain cannot be physically optimized.

By default, the command generates a summary report. To generate a detailed report for a specific scan chain, use the *-chain_name* option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example checks for scan chain structural consistency.

```
prompt> check_scan_chain
****************************************
Report : SCANDEF check
 ...

****************************************
  Checking between SCANDEF file and design:

  Total SCANCHAINS checked: 6
  VALIDATED :  6
  FAILED    :  0

  Chain name  Status  #cells  #bits  PARTITION   Scan in      Scan out
  268         V       58      58     PLLCKIN_20  i1/DMAX21/Z  i4/reg_1/TI
  269         V       58      58     PLLCKIN_20  i1/DMAX22/Z  i4/reg_2/TI
  270         V       58      58     PLLCKIN_20  i1/DMAX23/Z  i4/reg_3/TI

check_script

Statically check a script using the a static Tcl syntax checker based on TclPro Procheck and the Synopsys checking extensions for this tool.

Syntax

string *snpsTclPro::check_script* [-no_tclchecker_warning]

[-quiet] [-onepass] [-verbose] [-suppress *messageID*] [-application *appName*] [-W1] [-W2] [-W3] [-Wall] *filePattern*

```
string messageID
string appName
string filePattern
```

Arguments

`-no_tclchecker_warning`

Don't warn that TclDevKit cannot be found

`-quiet`

prints minimal error information

`-onepass`

perform a single pass without checking proc args

`-verbose`

prints summary information

`-suppress messageIDs`

prevent given messageIDs from being printed

Feedback

`-application` *`appName`*

Check script against application other than this one

`-W1`

print only error messages

`-W2`

print only error and usage warnings

`-W3`

print all errors and warnings

`-Wall`

print all types of messages (same as W3)

`filePattern`

file(s) to be checked

USING THE PACKAGE

The *check_script* command is in the snpsTclPro Tcl package, and all of the commands in this package are defined in the namespace snpsTclPro. The way to use this command is to load the package, which will import the commands it exports into the global namespace. This is shown below.

```
shell> package require snpsTclPro
1.0
```

These commands can be added to the .synopsys setup file for the system, user, or current directory, or the commands can be typed when the package is needed.

Description

The *check_script* command simplifies running the TclDevKit tclchecker program. This application is available for purchase from ActiveState (http://www.activestate.com). If the TclDevKit is not available then there is a limited Synopsys Tcl syntax checker that is used by this command. The Synopsys version of this code does not understand Tcl8.4 constructs, and some other checking is limited.

These checkers will check builtin Tcl commands, as well as the Synopsys extension commands which are found in the script. *check_script* will locate the Synopsys checking extensions for the application and will then invoke the checker. The limited checker does not require any external license. It is part of the Synopsys installation.

The *check_script* command will raise a Tcl error if the checker detects errors in the scripts being checked.

Feedback

The *check_script* command is provided as a convenience to streamline the use of the syntax checker within Synopsys applications. The checker can also be called directly on scripts, without requiring a license for the Synopsys application whose script is being checked. This checker script is available in the auxx/tcllib/bin/check_script in the installation directory of your application. When run standalone the -application option must be specified.

Synopsys Checker Extensions

The Synopsys extensions to the TclPro checker define a number of new warnings and errors. These messages are listed below, along with a short explanation of them.

Error *MisVal*

An option to a command which requires a value is missing its value.

Error *MisReq*

A required option or argument was not specified.

Error *Excl*

Two options which are mutually exclusive were both specified.

Error *ExtraPos*

An extra positional argument was specified to a command.

Error *BadRange*

The value specified for a given argument was outside of the legal range.

Error *UnkCmd*

The command specified is not known by the application.

Error *UnkOpt*

The specified option is not legal for the command.

Error *AmbOpt*

The option specified is not complete and matches 2 or more options for the command.

Warning *NotLit*

This warning indicates that the argument specified to an option was not a literal and therefore could not be checked. This message is suppressed by default. It can be enabled by setting the environment variable SNPS_TCL_NOLITERALWAN to true.

Warning *DupIgn*

Feedback

An option was specified multiple times to the command, and the first value specified will be the one used. The other values will be ignored.

Warning *DupOver*

An option was specified multiple times to the command, and the last value specified will be the one used. The other values will be ignored.

Examples

```
shell> check_script myscript.tcl

Loading snps_tcl.pcx...
Loading coreConsultant.pcx...
scanning: /u/user1/myscript.tcl
checking: /u/user1/myscript.tcl
test.tcl:3 (warnVarRef) variable reference used where variable name
 expected
set $a $b
    ^
test.tcl:5 (SnpsE-MisReq) Missing required positional options for
 foreach_in_collection: body
foreach_in_collection x {
}
^
test.tcl:9 (SnpsE-BadRange) Value -1 for 'index_collection index' must be
 >= 0
index_collection $a -1
child process exited abnormally
Error: Errors found in script.
        Use error_info for more info. (CMD-013)

shell> check_script -Wall anotherScript.tcl

Loading snps_tcl.pcx...
scanning: /u/user1/anotherScript.tcl
checking: /u/user1/anotherScript.tcl
```

CAVEATS

The Synopsys extension messages cannot be suppressed.

Aliases and abbreviated commands will be flagged as undefined procedures.

---

check_secondary_pg_placement_constraints

Check the conflicts between secondary pg constraints, UPF and existing pg straps.

Feedback

Syntax

status *check_secondary_pg_placement_constraints*

`[-blocks]`

Arguments

`-blocks`

This is an optional option.-blocks taks a list of linked block designs. For the block designs that specified with -blocks, check_secondary_pg_placement_constraints will check the secondary pg conflicts for those blocks only. Note, the check_secondary_pg_placement_constraints command does not check the subblocks inside the specified blocks recursively.

Description

This command will check the following conflicts related to secondary pg constraints.

- conflicts between secondary pg constraints and UPF/netlist These conflicts refer to the situation when a secondary pg constraint with -exclude_supply is specified to indicate that certain supply is not available, however, the same supply is already used for power management cells in UPF or is used to power existing cells/ports in netlist.

-conflicts between user specified secondary pg constraints and existing pg straps These conflicts refer to the situation when a user specirfied secondary pg constraint with -exclude_supply indicating certain supply being not available, however, the pg straps indiate otherwise. It can also refers to situation when a user specified secondary pg constraint with -supply indicating certain supply being available, however the pg straps do not exist.

-conflicts between user sepecified secondary pg constraints and tool derived secondary pg constraints These conflicts refer to the situation when a user specified secondary pg constraint wih -supply indicating this supply being available in certain region, but tool derived secondary pg constraints suggest that either this supply is not available or this supply exists in somewhere else. It can also refers to the situation when a user specified secondary pg constraints with -exclude indicating this supply being not available, but tool derived secondary pg constraints suggest that this supply is available based on existing pg straps.

Examples

The

```
prompt> check_secondary_pg_placement_constraints
```

Feedback

---

check_shapes

Checks and reports all the shapes which meet a specified condition in the current block.

Syntax

status *check_shapes*

```
[-uncolored]
[-floating]
[-mask_constraints]
[-layers layer_list]
[-max_shapes max_shapes_num ]
[-include include_list ]
```

Data Types

layer_list	collection
max_shapes_num	integer
include_list	list

Arguments

`-uncolored`

Checks and reports uncolored shapes in the current block. A summary of the total count of uncolored shapes found are printed. At least one of these options is required: *-uncolored*, *-mask_constraints*, or *-floating*. This option is mutually exclusive with the *-mask_constraints* option.

`-floating`

Checks and reports floating shapes in the current block. A summary of the total count of floating shapes found are printed. At least one of these options is required: *-uncolored*, *-mask_constraints*, or *-floating*.

`-mask_constraints`

Checks and reports mask constraint violating shapes and tracks in the current block. A summary of the total count per layer is printed. This option is mutually exclusive with the *-uncolored* option.

Feedback

`-layers`

Specifies the layers where shapes are checked.

`-max_shapes`

Specifies the maximum number of shapes to be written out in the report. The valid values for this option range from 1 to 65535. The default is 100.

`-include` *`include_list`*

Specifies which type of the cells to be included to check shapes. By default, only the top shapes are checked. The valid values are:

- **`module`**: Cells where is_soft_macro attribute is true.
- **`macro`**: Library cells where is_hard_macro attribute is true.
- **`lib_cell`**: Library cells where is_hard_macro attribute is false.
- **`fill`**: Fill cells.

Description

Checks and reports all the shapes which meet a specified condition in the current block. The shapes are not only layer shapes but also via shapes.

Examples

The following example checks and reports uncolored shapes in the current block.

```
prompt> check_shapes -uncolored

---

check_signal_elevation

Check and report signal elevation quality and coverage.

Syntax

status *check_signal_elevation*

```
[-max_route_layer layer_name]
[-max_route_length length]
```

Data Types

```
layer_name        string
length            float
```

Arguments

`-max_route_layer layer_name`

Specifies the maximum routing layer for port terminal creation. When not specified, the default is the top routing layer in the tech file.

`-max_route_length length`

Specify maximum route length from signal driver pin to signal elevation port. Any route length exceeding this length will be reported as a violation.

Description

This command checks the design's signal elevation quality. The report has three sections:

```
1. Coverage report: coverage percentage is reported as the ratio of
 elevated nets to total nets.
```

Feedback

```
2. Route length report: each elevated signal's buffer output to port
 route length is reported.
   Any route length more than the specified maximum route length is
 reported as a violation.
3. Integrity report: logical and physical violations are reported.
```

Examples

```
prompt> check_signal_elevation -max_route_layer METAL12

prompt> check_signal_elevation -max_route_length 1.5
```

---

check_stage_settings

Compares current application option settings against set_technology, set_qor_strategy, and set_stage.

Syntax

status *check_stage_settings*

```
-metric timing | leakage_power | total_power
-stage pnr | synthesis
-step synthesis | placement | cts | post_cts_opto | route | post_route
[-high_effort_timing]
[-reduced_effort]
[-reset_app_options]
```

Data Types

file_name string

Arguments

-metric *timing | leakage_power | total_power]*

Specifies the target metric to use when checking application options set by set_qor_strategy. Valid metric names are "timing", "leakage_power", and "total_power".

o *timing* checks application options that optimize for the best timing without focusing on the lowest power.

o *leakage_power* checks application options that optimize for the best timing and leakage power.

o *total_power* checks application options that optimize for the best timing and total power.

Feedback

`-stage pnr | synthesis`

Specifies the stage name associated with set_qor_strategy. Valid stage names are "synthesis" or "pnr". You can specify only one stage name.

`-step synthesis | placement | cts | post_cts_opto |route | post_route`

Specifies the step to use when checking application options set by set_stage. Valid step names are "synthesis","placement", "cts", "post_cts_opto", "route", and "post_route"

`-high_effort_timing`

When check_stage_settings is executed it reports application options set by set_qor_strategy with high_effort_timing switch

`-reduced_effort`

When check_stage_settings is executed it reports application options set by set_qor_strategy with reduced_effort switch

`-reset_app_options`

When check_stage_settings is executed, if any non recommended application option settings are detected for set_technology, set_qor_strategy, or set_stage, then that mega-switch command is reapplied.

Description

This command compares app option settings in the current design against recommended set_technology, set_qor_strategy, and set_stage application option settings. The command reports any setting differences identified in the current design.

In the current design the *-reset_app_options* switch is used to reset the select application options with non recommended settings to their recommended settings. If any non recommended settings are detected for set_technology, set_qor_strategy, or set_stage, then that mega-switch command is reapplied.

Examples

The following example compares the application option settings for the current technology node, "set_qor_strategy -metric timing -stage pnr", and "set_stage -step cts".

```
prompt> check_stage_settings -metric timing -stage pnr -step cts

 ########## Compare SET_TECHNOLOGY SETTINGS #########

Information: No difference found between current and recommended
 set_technology settings.

 ########## Compare SQS SETTINGS #########
Information: Evaluating single metric strategy for timing metric_target
Information: Applying set_qor_strategy settings for technology node 5.
```

Feedback

```

check_starrc_in_design

validates a configuration file for running In-Design signoff extraction with the StarRC tool.

Syntax

status *check_starrc_in_design*

`-effort` *`low | medium | high`*

Data Types

`effort` `string`

Feedback

Arguments

`-effort low | medium | high`

- *low*(the default) - to check the settings specified in the config file in set_starrc_in_design for config file path, starrc image path, layer mapping file path, corner mapping, version checks.
- *medium* - to create StarRC command file in Check_StarRC_DesignName sub-directory for users to review or run standalone StarRC, in addition to low effort check.
- *high* - to run StarRC with the generated command file and put the StarRC data in the Check_StarRC_DesignName sub-directory for users to check, in addition to medium effort check.

Description

This command validate the configuration file or run StarRC by using the derived command file with three levels of the validation efforts.

See Also

- set_starrc_in_design
- report_starrc_in_design

---

check_supply_equivalence

Check the supply nets are equivalent.

Syntax

status *check_supply_equivalence*

```
supply_nets
[-functional]
[-pst]
[-verbose]
```

Data Types

supply_nets	list

Arguments

supply_nets

Specifies the supply nets to be checked. The command fails if the number of supply nets are less than two.

Feedback

`-functional`

Specifies that the check is based on functional equivalence. If this options is not specified, the check is based on electrical equivalence by default. This option is mutually exclusive with *-pst* option.

`-pst`

Specifies that the check is based on PST-equivalence. If this options is not specified, the check is based on electrical equivalence by default. This option is mutually exclusive with *-functional* option.

`-verbose`

Shows the groups of equivalent supply nets.

Description

The *check_supply_equivalence* command checks whether the specified supply nets are equivalent or not. This command returns 1 if the supply nets are equivalent, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example compares two supply nets that are not electrically equivalent.

```
prompt> check_supply_equivalence {vdda vddb}
 0
```

The following example compares two supply nets that are functional equivalent.

```
prompt> check_supply_equivalence {vdda vddb} -functional
 1
```

The following example compares two supply nets that are pst-equivalent.

```
prompt> check_supply_equivalence {vdda vddb} -pst
 1
```

The following example compares supply nets that are not equivalent and shows the groups of equivalent supply nets.

```
prompt> check_supply_equivalence {vdd1 vdd2 U0/vdd1} -verbose
Information: List of supplies grouped by equivalence - {vdd1 U0/vdd1}
 {vdd2}. (UPF-183)
 0
```

Feedback

---

check_targeted_boundary_cells

Checks placement violations of the boundary cells around target objects in the current design.

Syntax

status *check_targeted_boundary_cells*

```
-target_objects {target_objects}
[-include_touching_placement_blockages]
[-error_view view_name]
```

Data Types

target_objects	list
view_name	string

Arguments

`-target_objects {target_objects}`

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified. This option is a required option.

`-include_touching_placement_blockages`

Specifies that placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

`-error_view view_name`

Specifies the name of the generated error view. Error view data is saved to a file in XML format with the specified name. No attachment is created nor saved into the design database. If the view_name file already exists under current directory, the file will be overwritten. The file extension must be specified as ".err", otherwise it is ignored. If no extension is specified, the ".err" extension is appended to the file name.

Feedback

Description

This command checks placement violations of boundary cells around target objects according to the boundary cell rules set by *set_boundary_cell_rules*. The violations can be classified as:

1. Continuity Violation:

For this rule, all the boundary cells should be a complete circuit. If no, there will be a violation. If user only insert boundary cells along all the left and right edges, the boundary cells should cover all the left and right edges. If no, there will be a violation.

1. Corner And Boundary Cell Violation:

This rule requires that all the corner and boundary cells are at the correct location.

1. Orientation Violation:

This rule requires that all the corner and boundary cells are at the correct orientation.

1. Short Edge And Segment Violation:

This rule requires that the length of each horizontal edge of every macro (including hard keepout margin), hard placement blockage, voltage area (including guard band) must be greater than the threshold specified by the option *-min_horizontal_jog*. If not, there will be a violation. This rule also requires that the length of each segment must be greater than the threshold specified by the option *-min_row_width*. If not, there will be a violation.

This command does not check if there is no_1x violation and does not honor the following 4 options of the *set_boundary_cell_rules* command:

-tap_distance

-prefix

-separator

-do_not_swap_top_and_bottom_inside_corner_cell

Examples

The following example checks for continuity violations, correct corner and boundary cell violations or correct orientation violation in current targeted boundary cells placement.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight \\
            -top_boundary_cells myLib/CellTop \\
            -bottom_boundary_cells myLib/CellBottom
prompt> check_targeted_boundary_cells -target_objects {PB_7 PB_8}
```

Feedback

---

check_tcd_cells

Checks TCD cell placement in the current design and writes out results to the Error Browser.

Syntax

status *check_tcd_cells*

```
-lib_cells lib_cells
-window_size {width height}
-window_step {x y}
[-include_small_windows]
```

Data Types

```
lib_cells  list of lib cells
width      float
height     float
x          float
y          float
```

Arguments

`-lib_cells lib_cells`

Specifies the TCD library cells.

`-window_size {width height}`

Specifies the window size width and height.

`-window_step {x y}`

Specifies the x- and y-increment for the next window.

`-include_small_windows`

Includes small windows at the last row and column for TCD checking. By default, the command excludes small windows.

Feedback

Description

This command checks if TCD cells exists in each window. You can use the Error Browser to check the results. Each window is the size specified by the *-window_size* option. The first window starts at the lower-left corner of the core. The next window moves both horizontally and vertically by the step specified by the *-window_step* option. If the window step is smaller than the window size, there will be overlaps between adjacent windows. Overlaps ensure that there is a TCD cell within the window size area.

For example, if the core bounding box has corners at (0,0) and (100,100), the window size is (50,50), the window step is (25,25), and the *-include_small_windows* option is specified, there will be a total of 16 windows as follows:

```
(0,0) - (50,50)
(25,0) - (75,50)
(50,0) - (100,50)
(75,0) - (100,50)
(0,25) - (50,75)
(25,25) - (75,75)
(50,25) - (100,75)
(75,25) - (100,75)
(0,50) - (50,100)
(25,50) - (75,100)
(50,50) - (100,100)
(75,50) - (100,100)
(0,75) - (50,100)
(25,75) - (75,100)
(50,75) - (100,100)
(75,75) - (100,100)
```

Examples

The following example checks if one TCD cell named DM1 exists in each window of size (50,50) and window step of (25,25), including small windows.

```
prompt>  check_tcd_cells -lib_cells { DM1} -window_size {50 50} \\
  -window_step {25 25} -include_small_windows
```

---

check_timing

Checks for possible timing problems in the current design.

Feedback

Syntax

status *check_timing*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
[-all]
[-format detail|list_only|json]
[-max_message_count count_value]
[-include check_list]
[-exclude check_list]
[-override_defaults check_list]
```

Data Types

check_list	list
mode_list	list
corner_list	list
scenario_list	list

Arguments

`-modes mode_list`

Specifies the modes for which to do the timing checks. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is checked separately. If this option is not given, the command does checks for every scenario that is active with the specified corner(s). It is an error to give this option with the *-scenarios* option.

`-corners corner_list`

Specifies the corners for which to do the timing checks. Each active scenario of the modes specified by the *-modes* option and the corners specified by the *-corners* option is checked separately. If this option is not given, the command does checks for every scenario that is active with the specified mode(s). It is an error to give this option with the *-scenarios* option.

`-scenarios scenario_list`

Specifies the scenarios for which to do the timing checks. Each of the specified scenarios is checked separately. It is an error to give this option with the *-modes* or the *-corners* options. If none of the *-modes*, *-corners*, or *-scenarios* options are specified, the command does checks for all active scenarios and all modes of the design.

`-include check_list`

Adds the checks listed in *check_list* to the default checks. It is an error to give this option with the *-all* option.

Feedback

`-exclude` *`check_list`*

Subtracts the checks listed in *check_list* from the default checks.

`-override_defaults` *`check_list`*

Overrides the default checks by using the argument specified in *check_list*. It is an error to give this option with the *-all* option. The options *-include*, *-exclude* and *-override_defaults* can be used together, the precedence is *-exclude* > *-include* > *-override_defaults*.

`-all`

Performs all the checks listed in the following *check_list*. It is an error to give this option with the *-include* or the *-override_defaults* option.

`-format` *`format_value`*

Gives output for check_timing command in a new format specified in place of *format_value*. The *format_value* can take any one of the three mentioned formats at a time. It is an error to specify more than one format value with *-format* option.

- detail
- list_only
- json

The alphabetically ordered list below shows the meaning of each format: All three arguments can be used with *-include*, *-exclude* and *-override_defaults* options.

`detail`

Gives detailed output for the default checks in the format specified by stdMsgService. This option shows a summary table that also includes passing checks and then detailed section with information about each instance of a failing check.

`list_only`

Gives a table that shows the maximum limit of messages that is set on the default checks.

`json -path` *`path_value`*

Dumps the output of check_timing command in the json file created in the mentioned path *path_value*. It is an error to use json option without *-path* option.

Feedback

`-max_message_count` *`count_value`*

It only displays the limited amount of check messages for each instance in the output. The limit is mentioned as *count_value*. It can only be used with *-format* option.

`check_list`

Specifies the list of checks to be performed. Each element in this list is one of the following strings:

- clock_crossing
- data_check
- gated_clock
- generated_clock
- loops
- multiple_clock
- no_clock
- no_input_delay
- unconstrained_endpoints
- missing_dslg

Description

This command checks the timing attributes placed on the current design and issues warning messages as needed. The messages provide information that identifies and corrects potential errors. The warnings do not necessarily indicate design problems.

This command performs the default checks when no options are specified:

- gated_clock
- generated_clock
- loops
- no_clock
- no_input_delay
- unconstrained_endpoints

Feedback

The alphabetically ordered list below shows the meaning of each check:

clock_crossing

Checks clock interactions when there are multiple clock domains. If a clock launches one or more paths that are captured by other clocks, it will have an entry in the clock crossing report.

- If the two clocks are exclusive or asynchronous clocks, the path is marked with an asterisk (*).
- If the two clocks are set false path (*set_false_path* from clk1 to clk2), the path is marked with a pound sign (#).
- If all the paths between the two clocks are set as false paths, the path is not reported.

data_check

Warns if no clocked signal or multiple clocked signals reach a data check register reference pin. The analysis is done separately for each of the clocked domains.

gated_clock

Warns if the gated clock doesn't reach any register CP pin. The check only performs for ICG cells.

generated_clock

Checks the generated clock network. Five types of issues are reported:

- The definition point of the generated clock has no path to the source point.
- The generated clocks form a loop.
- The specified edge mismatch
- The generated clock is unexpanded
- The generated clock without clock period.

loops

Warns of combinational feedback loops. If the feedback loop is not broken by the *set_disable_timing* command, it is automatically broken by disabling one or more timing arcs.

multiple_clock

Issues a info when multiple clocks reach a register clock pin.

Feedback

no_clock

Warns if no clock reaches a register clock pin. In this case, no setup or hold checks are performed on data pins related to that clock pin, and the path starting at the clock pin is not relative to a clock.

no_input_delay

Warns if no clock-related delay is specified on an input port, where it propagates to a clocked latch or output port.

unconstrained_endpoints

Warns about unconstrained timing endpoints. This warning identifies the reason of the unconstrained endpoints:

missing_dslg

Warns if no scaling library for a cell.

USAGE

There are two ways to run the *check_timing* command:

1. Use the *check_timing* command directly.

```
prompt> check_timing
Warning: The endpoint 'out1' is unconstrained by the reason of 'false
 path'.(TCK-001)
```

2. Use in the *check_design* flow.

   The *check_timing* command is integrated into the *check_design* command as "timing" checks. In the *check_design* flow, all the messages are organized by EMS.

```
prompt> check_design -checks timing
```

   This command triggers the *check_timing* command in the *check_design* flow and stores all the messages to the EMS database.

   You can redefine the *check_design* checks by using the *create_check_design_strategy* command. For example, to redefine the *timing* check so that it runs the *check_timing* command with the *-include* option, use the following commands:

```
prompt> create_check_design_strategy \\
   -define_check timing {check_timing -include {xx}}
prompt> check_design -checks timing
```

Multicorner-Multimode Support

By default, this command works on all active scenarios. To specify different scenarios, use the *-scenarios* option or the *-corners* and *-modes* options.

Feedback

Examples

The following example does default checks without any options:

```
prompt> check_timing
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
Warning: A loop 'u4/A u4/Z u3/A u3/Z' is detected, the arc 'u3/A to u3/Z'
  is disabled to break the loop. (TCK-011)
```

The following example adds the clock_crossing check:

```
prompt> check_timing -include {clock_crossing}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
Warning: The register launch clock 'clk1' and capture clock 'clk3'
  are from different domains. (TCK-010)
Warning: A loop 'u4/A u4/Z u3/A u3/Z' is detected, the arc 'u3/A to u3/Z'
  is disabled to break the loop. (TCK-011)
```

The following example removes the loops check:

```
prompt> check_timing -exclude {loops}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
```

The following example adds the clock_crossing check and removes the loops check:

```
prompt> check_timing -include {clock_crossing} -exclude {loops}
Warning: The register clock pin 'ff1/CP' has no fanin clocks. (TCK-002)
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
Warning: The register launch clock 'clk1' and capture clock 'clk3' are
  from different domains. (TCK-010)
```

The following example only does the *unconstrained_endpoints* check:

```
prompt> check_timing -override_defaults {unconstrained_endpoints}
Warning: The endpoint 'ff1/D' is unconstrained by the reason
  of 'unclocked'. (TCK-001)
```

The following example only does the *missing_dslg* check:

```
prompt> check_timing -override_defaults {missing_dslg}
Warning: No scaling library for cell 'U6' (libCell
 'ss_ff/HDBLVT08_ND2_2').
 (TCK-014)
```

The following example shows the usage of *-format* option with *detail*.

Feedback

```
prompt> check_timing -format detail

check_topology_feasibility

Check if a topology path match the actual path in user netlist

Feedback

Syntax

check_topology_feasibility

```
[-plan topologyPlanList]
[-from topologyNodeList]
[-to   topologyNodeList]
[-example]
```

Data Types

```
topologyPlanList list of string
topologyNodeList list of string
```

Arguments

`-plan` *topologyPlanList*

Operate only on topology edges found in the specified topology plans.

`-from` *topologyNodeList*

Operate only on topology paths starting from the specified topology nodes.

If *-plan* is also specified, topology nodes not found in the specifed topology plans will be skipped.

If *-to* is also specified, topology paths starting from the specified *-from* nodes and ending in the specified *-to* nodes will be selected for checking.

`-to` *topologyNodeList*

Operate only on topology paths ending in the specified topology nodes.

If *-plan* is also specified, topology nodes not found in the specifed topology plans will be skipped.

If *-from* is also specified, topology paths starting from the specified *-from* nodes and ending in the specified *-to* nodes will be selected for checking.

`-example`

Print a list of usage examples of this command.

Description

This command checks if a path in the netlist can be implemented by a specified topology path.

The topology path must be a "superset" of the path in the netlist. For example, the topology path can consist of feedthrough blocks or other blocks that are not found in the netlist path. But if the netlist path goes through a specific block, that block must exist in the topology path.

Feedback

Examples

In the following example, topology path matches netlist path:

```
# Topology Path = block A -> block E -> block Z
# Netlist Path  = block A -> block E -> block Z
prompt> check_topology_feasibility -plan T1 -from T1/A0 -to T1/Z0
1
```

In the following example, topology path goes through feedthrough block F but still matches the netlist path:

```
# Topology Path = block A -> block E -> block F -> block Z
# Netlist Path  = block A -> block E -> block Z
prompt> check_topology_feasibility -plan T1 -from T1/A0
1
```

In the following example, netlist path goes through block E but topology path doesn't, and therefore they don't match. User needs to add a topology node to cover block E and include the node in the topology path.

```
# Topology Path = block A -> block F -> block Z
# Netlist Path  = block A -> block E -> block Z
prompt> check_topology_feasibility -plan T1 -to T1/Z0
Cannot implement topology plan 'T1' because no topology node matches pin
 'E/out'
1
```

See Also

- create_topology_plan
- create_topology_node
- create_topology_edge
- report_topology_plans

---

check_topology_plans

Checks one or more topology plans during different stages of implementation. This command performs a sanity check on base topology plans or checks the quality of results after the topology plan is optimized.

Syntax

string *check_topology_plans*

```
[-filename file_name]
[-error_view view_name]
```

Feedback

```
[-mode check_mode]
plan_list
```

Data Types

```
file_name       string
view_name       string
check_mode      string
plan_list       list
```

Arguments

plan_list

Specifies the topology plans to check. By default, checking is performed on all topology plans in the design.

-filename *file_name*

Writes out the check results to the specified file name. By default, the command writes the check results to the console.

-error_view *view_name*

Specifies the name of the generated error view. The command saves the error view data to a file in XML format with the specified name. No attachment is created nor saved in to the design database. If the view_name file already exists under the current run directory, the command overwrites the file. If a file extension is specified, it must be ".err", otherwise it will be ignored. If no extension is specified, the command appends ".err" to the specified filename.

-mode *check_mode*

Specifies the mode of the check. The following modes are supported:

pre_optimization : Performs a sanity check of the topology plans before optimization

post_optimization : Checks the quality of the topology plan optimization results

pre_implementation : Performs a sanity check of the topology plans before implementation

post_implementation : Checks the quality of the topology plan implementation results

Examples

The following example checks the current topology plan after performing optimization with the *optimize_topology_plans* command.

Feedback

```
prompt> check_topology_plans -mode post_optimization
 [current_topology_plan]
No violation has been found.
```

See Also

- characterize_topology_plans
- optimize_topology_plans

---

check_variants

Checks attributes across physical variant group for consistency.

Syntax

collection *check_variants*

```
[-dont_use]
[-included_purposes]
```

Arguments

`-dont_use`

Specifies an optional argument to select checking the dont_use attribute.

`-included_purposes`

Specifies an optional argument to select checking the included_purposes attribute.

Description

The *check_variants* command is a convenience checker that can look at the dont_use and included_purposes attributes on library cells in a variant group for consistency. By default, the command checks both attributes, but you might select only one to check by using the corresponding command argument. The command displays the member library cells of any variant group as output in which the attribute value is not the same for all library cells and return the same set of library cells in a collection.

Examples

The following command checks the dont_use attribute for consistency across all cell groups:

```
prompt> check_variants -dont_use
```

Feedback

check_vclp_design

Used to invoke and perform verification using VC LP.

Syntax

status *check_vclp_design*

```
[-golden_upf_files]
[-write_verilog_options]
[-save_upf_options]
```

Data Types

```
-golden_upf_files           string
-write_verilog_options           string
-save_upf_options           string
```

Arguments

`-golden_upf_files`

If FC/ICC2 has Golden UPF Mode enabled, VC LP can be invoked only in Golden UPF Mode and this command option is mandatory. This option can take a list of one or more Golden upf file paths. The file paths must be enclosed in "". The supplemental UPF along with the name map file will be automatically written out by check_vclp_design and VCLP will be run in golden UPF mode.

`-write_verilog_options`

This option is used to specify additional command options to the write_verilog command that will be invoked under the hood in check_vclp_design.

`-save_upf_options`

This option is used to specify additional command options to the save_upf command that will be invoked under the hood in check_vclp_design.

Description

The *check_vclp_design* command is used to invoke VCLP from within ICC2/Fusion Compiler and perform verification using VCLP. The VC_STATIC_HOME environment variable must be set, prior to the invocation of this command. To read the design and perform the checks, VCLP sources a template file whose parameters are set up by *check_vclp_design*. Unless users specifically set up the template file by setting the environment variable ICC2_VCLP_TEMPLATE, the template file used by VCLP will be sourced based on the VC_STATIC_HOME setting. The default template is sufficient for most users.

Feedback

Following is a list of actions the *check_vclp_design* command performs:

- Opens up VCLP (vc_static_shell) from inside ICC2/Fusion Compiler.
- Performs all the initializations needed for VCLP including setting up the required parameters for VCLP Template file.
- Detects the reference libraries used in the ICC2/Fusion Compiler Run (.nlib files) and extracts the path for the corresponding .db files from the .nlib files and feeds the .db files to VCLP
- Invocation of this command triggers a full run of VCLP. (Verilog netlist and UPF are written out internally and passed as input to VCLP)
- Keeps a communication channel open with VCLP so that users can interact with VCLP with other commands such as *vclp_exec_cmd* or *vclp_zoom_highlight*.

The default write_verilog/save_upf written out internally by check_vclp_design is as below: save_upf -exclude {corner_cells cover_cells end_cap_cells filler_cells pad_spacer_cells physical_only_cells} write_verilog -exclude {leaf_module_declarations corner_cells cover_cells end_cap_cells filler_cells pad_spacer_cells physical_only_cells} -hierarchy all

For designs with block abstracts, ETM, Budget shell, Blackboxes; users will need to edit the template file and point to the new template file with the ICC2_VCLP_TEMPLATE environment variable.

The -golden_upf_files option is mandatory when Golden UPF Mode is enabled. The -write_verilog_options and -save_upf_options command options can only be used in combination and not separately.

---

classify_lib_cell_attributes

Execute lexical classification to extract possible lexical attributes from library cell name.

Syntax

status *classify_lib_cell_attributes*

```
-library library_object_list | -libset libset_name_string
[-check_only]
[-incremental naming_convention_name_string]
```

Feedback

Data Types

library_object_list	list-of-library-objects
libset_name_string	string
naming_convention_name_string	string

Arguments

`-library` *library_object_list*

A set of libraries to run lexical classification.

`-libset` *libset_name_string*

A libset including a set of libraries to run lexical classification.

`-check_only`

Run under the check-only mode, the classified attributes will not be stored.

`-incremental` *naming_convention_name_string*

Run under incremental mode using the given naming convention, only the library cells have not been classified yet will be processed.

Description

The purpose of lexical classification is trying to extract library cell lexical properties from the library cell name. This requires the library cells are named with a consistent, well-defined meaningful naming convention.

A meaningful library cell naming may include additional information, which are not necessary visible in the library contents. For example, library cell designers may mark circuit topology variants, device types, etc. on the library cell names.

To do this lexical classification, each library's library cell naming convention must be property defined using *set_lib_cell_naming_convention*. For some naming convention, naming keywords may need to be defined with *set_lib_cell_naming_keywords*.

Here is an usage example:

```
# Define naming convention
set_lib_cell_naming_convention -library [get_lib libA] -column 1 -pattern
 {[A-Z0-9]*} -attribute "lexical_cell_prefix_name"
set_lib_cell_naming_convention -library [get_lib libA] -column 2 -pattern
 {D[0-9]*}   -attribute "lexical_drive1_name"
set_lib_cell_naming_convention -library [get_lib libA] -column 3 -pattern
 {FINFET}    -attribute "lexical_device_type"
set_lib_cell_naming_convention -library [get_lib libA] -column 4 -pattern
 {[A-Z]*}    -attribute "lexical_device_threshold_voltage"

# Run classification
classify_lib_cell_attributes -library [get_lib libA]
```

Feedback

After lexical classification, check the results with *report_lib_cell_classification_attributes*, *report_lexical_unclassified_lib_cells*, and *report_lexical_ignored_lib_cells*.

If the results are not as expected, check the defined of library cell naming convention.

Due to the complexity and unpredictability of library cell namings, a library may not have a consistent naming convention for all the library cells. It is also possible that a library names the library cells with ambiguity. In such case, some library cells may not be automatically and successfully classified by this command in a single run.

In such case, if the users are still interested in using lexical attributes on those remaining unclassified library cells, they can try incremental classification with *-incremental* by providing different library cell naming conventions to process them. Or, manually setting lexical attributes with *set_lib_cell_classification_attributes* is always an option.

---

clock_opt

Synthesizes and routes the clocks in the current block and then further optimizes the design based on the propagated clock latencies.

Syntax

status *clock_opt*

```
[-list_only]
[-from build_clock | route_clock | final_opto ]
[-to build_clock | route_clock | final_opto ]
```

Feedback

Arguments

`-list_only`

This option prints the major stages of the *clock_opt* command. These stages are

- build_clock • route_clock • final_opto

The option cannot be used with the *-from* or *-to* options.

`-from build_clock | route_clock | final_opto`

Specifies the first stage of the *clock_opt* command. Valid values are *build_clock*, *route_clock*, *final_opto*.

If you do not specify this option, the flow begins with the build_clock stage.

`-to build_clock | route_clock | final_opto`

Specifies the last stage of the *clock_opt* command. Valid values are *build_clock*, *route_clock*, *final_opto*.

If you do not specify this option, the flow ends with the final_opto stage.

Description

The default behavior of this command is as follows:

1. Synthesizes and optimizes the clock trees.
2. Completes the detail routing of the clock trees.
3. Further optimizes the design for timing,electrical DRC violations, area, power, and routability, based on actual propagated clock latencies, and legalizes the design placement.

The final_opto stage begins with optimization, followed by timing-driven placement and legalization. This stage then runs a full global route, and follows that with extensive global route-based optimization. The global route-based optimization performs incremental legalization and routing patch-up. The output of the final_opto stage is a design having all signal nets global routed and timing based on actual routing. The subsequent signal routing flow (*route_auto*,*route_global*, or *route_group*) will automatically skip global routing. It is recommended that the user does not change global routing / shapes after clock_opt in order to avoid errors during subsequent track and detailed routing.

The final_opto stage may be executed once only in the flow.

Router setup

This command does have a dependency on router-related application options. The user should ensure that all routing rules, route guides, and app_option settings required for the technology node are enabled prior to clock_opt. Commands related to via ladder refresh

Feedback

are included within the final_opto stage itself and should not be run either before or after this stage.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information. It is recommended that all scenarios enabled for post-route optimization also be enabled for the final_opto stage.

Timer setup

It is recommended that timer settings enabled for post-route optimization (eg. AWP, ccs, etc.) also be enabled for the final_opto stage. The exception is time.si_enable_analysis, which is recommended to be set to false but can be optionally set to true if the user desires additional estimation of SI timing effect to be factored into the global route timing.

Flow Hooks

Within the final_opto stage itself, two pre-defined procedures exist to support the capability to run routing-related commands prior to the global routing. These procedures can be used to run filler insertion commands or net prerouting. Flow hook *snps_clock_opt_pre_gr* is executed just prior to the intial full global route and flow hook *snps_clock_opt_filler_insertion* is executed just ahead of the incremental global routing at the end of optimization.

Examples

The following example synthesizes, optimizes, and routes the clock trees in the current block, followed by further circuit optimization on the block. The result is an optimized design with legalized placement and global routed signal nets :

```
prompt> clock_opt
```

The following example takes a placed design with synthesized clock trees as its input. It first routes the clock trees, and then optimizes the block for timing, electrical DRC violations, power, area, and routability. The result is an optimized block with legalized placement and global routed signal nets.

```
prompt> clock_opt -from route_clock -to final_opto
```

The following example takes a design with synthesized and routed clock trees as its input. During the execution of the final_opto stage, flow hook *snps_clock_opt_pre_gr* is used to detail route a net which is not expected to need further optimization and which needs to be pre-routed.

```
prompt> proc snps_clock_opt_pre_gr { }
          route_group -net <net>
        }

prompt> clock_opt -from final_opto
```

Feedback

---

clone_macro_group_packing

Copies the macro group packing from one group to another.

Syntax

```
status clone_macro_group_packing
-source source_macro_group
-destinations destination_of_macro_groups
-orientation orientation_string
```

Data Types

```
source_macro_group           string
destination_of_macro_groups  collection of macro groups
orientation_string           one of R0, MX, MY, R180
```

Arguments

`-source source_macro_group`

Specifies source macro group.

`-destinations destination_of_macro_groups`

Specifies destination macro groups.

`[-orientation R0|MX|MY|R180]`

Specifies whether to flip in place each of the destination groups.

Description

This command copies macro grouping packing from a source macro group to one or more destination macro groups. For each destination macro group, the command applies the following heuristic:

1. Checks the number of macros between the source macro group and the destination macro group. If the number of macros is not the same, the command skips this destination group and does nothing.
2. Sorts macros in the source macro group and destination macro group based on macro names. Each macro in the source macro list must correspond to the macro of destination macro list at the same location in the list.
3. Compares corresponding macros from these two macro list one-by-one. If any two macros have different sizes, the packing cannot be copied and the destination group is skipped.

Feedback

4. Copies the contour of source macro group to destination macro group in an appropriate location.
5. Copies the location of each macro in the source macro group to the corresponding macro in the destination macro group. These two macros will have same relative locations to their contours.
6. If -orientation is provided and the value is not R0, the destination group is flipped. The result of flipping is the same as applying flip_macro_group command.

Examples

The following example copies the packing of macro group G1 to destination G2 and G3.

```
prompt> clone_macro_group_packings -source G1 -destinations {G2 G3}
```

See Also

- clone_macro_group_packing

- get_macro_group_packing_clone_candidates
- flip_macro_group

---

close_blocks

Closes one or more opened block, releasing them from memory when it is no longer used.

Syntax

status *close_blocks*

```
[-save]
[-force]
[-purge]
[blocks]
```

Data Types

blocks	collection

Arguments

`-save`

This option is used to save the block before closing it (if necessary). This will prevent a failure in the event a close would cause a purge and the block has been modified but not saved.

Feedback

`-force`

This option is used to force the block to be closed regardless of whether or not it has been saved. It can be used instead of the *-save* option to force the close but without affecting a save for an open and modified block.

`-purge`

This option is used to force block from memory, regardless of how many times it has been opened. This seems unsafe but is not since all applications note when blocks are removed from memory. It can be somewhat drastic, so it should be used with care.

`blocks`

A block name with optional library, label, and view specifications, or a collection of blocks. If the library specification is not present, the *current_lib* is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then *design view* is used. If the option is not given, the *current_block* is used.

Description

This command decrements and open block's open count and removes one or more block from memory when the reference count drops to 0 (or if the *-purge* option is used). It will fail if the block has been modified but not yet saved, and reference count would drop to 0 causing the block to be removed from memory, and the *-save* or *-force* option are not used. In the case where the *-save* option is used, the block is saved (only if necessary) before the reference count is decremented. If the *-force* option is used, the command proceeds regardless of the modify status. Please use this option carefully as it is possible to lose data. The *-purge* option is used to force a removal of the block from memory, regardless of its reference count. It will fail if the block has been modified but not yet saved, unless the *-save* or *-force* option is used also.

This command returns the number of blocks removed and 0 if not. If an illegal name(with a slash) is given for the block, a TCL error is raised.

Examples

This example closes the current block.

```
prompt> close_blocks
1
```

This example forces closed the block Mid, which is being used in Top. This has two effects. First, the instances in Top of Mid become unbound. Second, the block Bot will also be purged since its reference count is decremented when Mid is closed.

```
prompt> close_blocks Mid
1
```

Feedback

This example closes the block Top, saving it in the process.

```
prompt> close_blocks -save Top
1
```

This example closes a modified and unsaved block that has been opened twice. The first close_blocks only decrements the reference to 1 but doesn't remove the block from memory yet. The second close_blocks would cause an error because the block hasn't been saved:

```
prompt> create_block Top
{top_lib:Top.design}

prompt> open_block Top
Information: Incrementing open_count of block 'top_lib:Top.design' to 2.
{top_lib:Top.design}

prompt> close_blocks Top
Information: Decrementing open_count of block 'top_lib:Top.design' to 1.
1

prompt> close_blocks Top
Error: close_blocks failed. Design 'Top.design' in library 'top_lib' is
 modified.
```

Feedback

close_drc_error_data

Closes a physical DRC error data collection.

Syntax

```
status close_drc_error_data
drc_error_data
[-save]
[-force]
```

Data Types

```
drc_error_data        collection
```

Arguments

drc_error_data

Specifies the collection of physical DRC error data objects to close.

-save

Saves the pending changes in the exported physical DRC error data before closing the error data file.

This option applies only to external error data files. If the error data file is attached to the current block, use the *save_block* command to save the error data file.

The *-save* and *-force* options, are mutually exclusive; you can specify only one.

-force

Closes the specified collection of physical DRC error data, discarding any unsaved pending changes.

The *-save* and *-force* options, are mutually exclusive; you can specify only one.

Description

The *close_drc_error_data* command decrements the open count of the specified error data collection.

The tool increments the open count for an error data file each time you run the *open_drc_error_data* or *create_drc_error_data* command for the error data file. The tool decrements the open count for an error data file each time you run the *close_drc_error_data* command. The error data collection is removed from memory when the open count reaches zero.

If the error data has unsaved pending changes, the command fails unless you use the *-save* or *-force* option.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example opens the external physical DRC error data file named my_design_dppinassgn.err, and then closes it.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> close_drc_error_data $data
1
```

close_ems_databases

Closes the EMS databases in memory.

Syntax

```
status close_ems_databases
[-save]
[ems_databases]
```

Data Types

```
ems_databases  list
```

Feedback

Arguments

`-save`

Writes the currently opened EMS databases to disk before closing them. By default, the EMS databases are not written to disk by this command.

`ems_databases`

List or collection of EMS databases to be closed.

Description

This command closes the current EMS database in memory, if no argument is specified. If a list or collection of EMS databases is provided as an argument, this command closes only the specified EMS databases, if they are open. The *-save* option writes the EMS databases to disk before closing them.

Examples

The following example closes the current EMS database, if present.

```
prompt> close_ems_databases
```

The following example writes out the current EMS database to disk, then closes it.

```
prompt> close_ems_databases -save
```

The following example closes all currently opened EMS databases.

```
prompt> close_ems_databases [get_ems_databases]
```

The following example saves and closes all currently opened EMS databases.

```
prompt> close_ems_databases -save [get_ems_databases]
```

Feedback

close_lib

Decrements the open count of a library. A library is removed from memory when its open count is zero.

Syntax

status *close_lib*

```
[-save_designs]
[-force]
[-purge]
[-all]
[-compress]
[-auto_saved_data keep | clear]
[library]
```

Data Types

```
library        collection
```

Arguments

`-save_designs`

Saves any designs in the design library that are open and modified but not yet saved. If the design library contains a technology section that has been modified, it is also saved.

When you use this option, the modified designs and technology section are saved regardless of whether the design library is removed from memory.

This option is not supported in the library manager.

`-compress`

To be used with "-save_designs" to save libraries in compressed format. This option is applicable to design library only. It is error to use this option without -save_designs.

`-force`

Removes the library from memory, even if its technology section or some of its designs have been modified but not saved (and you did not use the *-save_designs* option).

`-purge`

Removes the library from memory, regardless of its open count.

`-all`

Removes all libraries from memory, regardless of their open counts.

Feedback

`-auto_saved_data keep | clear`

Specifies whether to clear or keep auto_saved data of the library. By default, auto-saved data will be kept.

`library`

Specifies the library to close. This can either be a name or a collection of a single library.

By default, the command closes the current library.

Description

This command decrements the open count of the specified library. The command closes the library and removes it from memory when at least one of the following conditions is satisfied:

- The open count is zero.
- The *-purge* option is used.
- The *-force* option is used.

If you try to remove a library from memory that is on the reference library list of another open design library, the tool issues an error message and does not remove the library from memory.

In the library manager, you can use this command to remove a library from an aggregate library workspace.

Examples

The following example removes the current design library from memory after saving saving any open and modified-but-not-saved designs.

```
prompt> close_lib -purge -save_designs
1
```

The following example saves the open and modified-but-not-saved designs in all open design libraries and then removes the design libraries from memory.

```
prompt> close_lib -all -save_designs
1
```

---

close_rail_result

Closes the current rail result.

Syntax

status *close_rail_result*

Description

This command closes the current rail result.

Feedback

After the rail result is closed, you cannot access any rail analysis result information such as taps, voltage drop attributes, and power attributes.

Examples

The following example closes the current rail result.

```
prompt> open_rail_result static
prompt> get_attribute [ get_cell U35 ] static_power
1.0876e-06
prompt> close_rail_result
1
```

See Also

- analyze_rail
- open_rail_result
- report_rail_result

---

collection_to_list

Format collection contents as a Tcl list or Scheme string

Syntax

list *collection_to_list*

```
[-name_only]
[-no_braces]
[-brace_with_quotes]
[-newline]
[-truncate elem_count]
[-no_sort]
-objects object_list
obj_spec_list
```

Data Types

elem_count	int
object_list	collection
obj_spec_list	collection

Arguments

`-name_only`

Prints the object names without specifying the object types.

`-no_braces`

Prints the output list without beginning and closing curly braces.

Feedback

`-brace_with_quotes`

Replaces beginning and closing curly braces with quotes.

`-newline`

Print each object on a new line.

`-truncate` *`elem_count`*

Specifies the number of objects to print. The rest of the elements are truncated.

`-no_sort`

Does not sort the output data.

`-objects` *`object_list`*

Specifies the objects to format as a Tcl list.

This option is mutually exclusive with the *obj_spec_list* argument; you must specify either this option or the *obj_spec_list* argument.

`obj_spec_list`

Specifies the objects to format as a Tcl list.

This option is mutually exclusive with the *-objects* option; you must specify either this argument or the *-objects* option.

Description

The *collection_to_list* command prints a formatted Tcl list that corresponds to the collection provided as input. The Tcl list is sorted based on the object type and name (or only on the object name if you use the *-name_only* option). To output the list without sorting, use the *-no_sort* option.

Examples

The following example prints the Tcl list that corresponds to the collection passed as input.

```
prompt> collection_to_list [get_pins]
{{pin FF0/CLK} {pin FF0/D} {pin FF0/Q} {pin FF1/CLK} {pin FF1/D}
{pin FF1/Q} {pin SUB/A[0]} {pin SUB/A[1]} {pin U1/A} {pin U1/Y}}
```

The following example prints the object name only (without the object type) as a Tcl list.

```
prompt> collection_to_list [get_pins] -name_only
{FF0/CLK FF0/D FF0/Q FF1/CLK FF1/D FF1/Q {SUB/A[0]} {SUB/A[1]} U1/A U1/Y}
```

The follow example prints the Tcl list without beginning and ending curly braces.

```
prompt> collection_to_list [get_pins] -name_only -no_braces
FF0/CLK FF0/D FF0/Q FF1/CLK FF1/D FF1/Q {SUB/A[0]} {SUB/A[1]} U1/A U1/Y
```

Feedback

The follow example prints each object on a new line.

```
prompt> collection_to_list [get_pins] -newline
{{pin FF0/CLK}
{pin FF0/D}
{pin FF0/Q}
{pin FF1/CLK}
{pin FF1/D}
{pin FF1/Q}
{pin SUB/A[0]}
{pin SUB/A[1]}
{pin U1/A}
{pin U1/Y}}
```

The follow example prints the first five objects with each object on a new line.

```
prompt> collection_to_list [get_pins] -newline -truncate 5
{{pin FF0/CLK}
{pin FF0/D}
{pin FF0/Q}
{pin FF1/CLK}
{pin FF1/D}}
```

---

collections

Describes the methodology for creating collections of objects and querying objects in the database.

Description

Synopsys applications build an internal database of objects and attributes applied to them. These databases consist of several classes of objects, including designs, libraries, ports, cells, nets, pins, clocks, and so on. Most commands operate on these objects.

By definition:

A collection is a group of objects exported to the Tcl user interface.

Collections have an internal representation (the objects) and, sometimes, a string representation. The string representation is generally used only for error messages.

Collections represent an ordered sequence of database objects. These collections provide constant time random access to the objects contained in the sequence.

A set of commands to create and manipulate collections is provided as an integral part of the user interface. The collection commands encompass two categories: those that create collections of objects for use by another command, and one that queries objects for viewing. The result of a command that creates a collection is a Tcl object that can be passed along to another command. For a query command, although the visible output looks like a list of objects (a list of object names is displayed), the result is an empty string.

Feedback

An empty string "" is equivalent to the empty collection, that is, a collection with zero elements.

To illustrate the usage of the common collection commands, the man pages have examples. Most of the examples use PrimeTime as the application. In all cases, the application from which the example is derived is indicated.

Homogeneous and Heterogeneous Collections

A homogeneous collection contains only one type of object. A heterogeneous collection can contain more than one type of object. Commands that accept collections as arguments can accept either type of collection.

Lifetime of a Collection

Collections are active only as long as they are referenced. Typically, a collection is referenced when a variable is set to the result of a command that creates it or when it is passed as an argument to a command or a procedure. For example, in PrimeTime, you can save a collection of design ports by setting a variable to the result of the *get_ports* command:

```
pt_shell> set ports [get_ports *]
```

Next, either of the following two commands deletes the collection referenced by the *ports* variable:

```
pt_shell> unset ports
pt_shell> set ports "value"
```

Collections can be implicitly deleted when they go out of scope. Collections go out of scope for various reasons. An example would be when the parent (or other antecedent) of the objects within the collection is deleted. For example, if our collection of ports is owned by a design, it is implicitly deleted when the design that owns the ports is deleted. When a collection is implicitly deleted, the variable that referenced the collection still holds a string representation of the collection. However, this value is useless because the collection is gone, as illustrated in the following PrimeTime example:

```
pt_shell> current_design
{"TOP"}

pt_shell> set ports [get_ports in*]
{"in0", "in1"}

pt_shell> remove_design TOP
Removing design 'TOP'...

pt_shell> query_objects $ports
Error: No such collection '_sel26' (SEL-001)
```

Feedback

Iteration

To iterate over the objects in a collection, use the *foreach_in_collection* command. You cannot use the Tcl-supplied *foreach* iterator to iterate over the objects in a collection, because the *foreach* command requires a list, and a collection is not a list. In fact, if you use the *foreach* command on a collection, it destroys the collection.

The arguments of the *foreach_in_collection* command are similar to those of foreach: an iterator variable, the collection over which to iterate, and the script to apply at each iteration. Note that unlike the *foreach* command, the *foreach_in_collection* command does not accept a list of iterator variables.

The following example is an iterative way to perform a query in PrimeTime. For more information, see the *foreach_in_collection* man page.

```
pt_shell> \\
foreach_in_collection s1 $collection {
  echo [get_object_name $s1]
  }
```

Manipulating Collections

A variety of commands are provided to manipulate collections. In some cases, a particular command might not operate on a collection of a specific type. This is application-specific. Consult the man pages from your application.

- *add_to_collection* - This command creates a new collection by adding a list of element names or collections to a base collection. The base collection can be the empty collection. The result is a new collection. In addition, the *add_to_collection* command allows you to remove duplicate objects from the collection by using the *-unique* option.
- *append_to_collection* - This command appends a set of objects (specified by name or collection) to an existing collection. The base collection is passed in through a variable name, and the base collection is modified directly. It is similar in function to the *add_to_collection* command, except that it modifies the collection in place; therefore, it is much faster than the *add_to_collection* command when appending.
- *remove_from_collection* - This command removes a list of element names or collections from an existing collection. The second argument is the specification of the objects to remove and the first argument is the collection to have them removed from. The result of the command is a new collection. For example, in PrimeTime:

  ```
  pt_shell> set dports \\
  [remove_from_collection [all_inputs] CLK]
  {"in1", "in2", "in3"}
  ```

- *compare_collections* - This command verifies that two collections contain the same objects (optionally, in the same order). The result is "0" on success.

Feedback

- *copy_collection* - This command creates a new collection containing the same objects in the same order as a given collection. Not all collections can be copied.
- *index_collection* - This command extracts a single object from a collection and creates a new collection containing that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index. Not all collections can be indexed.
- *sizeof_collection* - This command returns the number of objects in a collection.

Filtering

In some applications, you can filter any collection by using the *filter_collection* command. This command takes a base collection and creates a new collection that includes only those objects that match an expression.

Some applications provide a *-filter* option for their commands that create collections. This allows objects to be filtered out before they are ever included in the collection. Frequently this is more efficient than filtering after the they are included in the collection. The following examples from PrimeTime filters out all leaf cells:

```
pt_shell> filter_collection \\
[get_cells *] "is_hierarchical == true"]
{"i1", "i2"}
pt_shell> get_cells * -filter "is_hierarchical == true"
{"i1", "i2"}
```

The basic form of a filter expression is a series of relations joined together with AND and OR operators. Parentheses are also supported. The basic relation contrasts an attribute name with a value through a relational operator. In the previous example, *is_hierarchical* is the attribute, **==** is the relational operator, and *true* is the value.

The relational operators are

```
==   Equal
!=   Not equal
>    Greater than
<    Less than
>=   Greater than or equal to
<=   Less than or equal to
=~   Matches pattern
!~   Does not match pattern
```

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only true or false.

Additionally, existence relations determine if an attribute is defined or not defined, for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
```

These operators apply to any attribute as long as it is valid for the object class. See the appropriate man pages for complete details.

Sorting Collections

In some applications, you can sort a collection by using the *sort_collection* command. It takes a base collection and a list of attributes as sort keys. The result is a copy of the base collection sorted by the given keys. Sorting is ascending, by default, or descending when you specify the *-descending* option. In the following example from PrimeTime, the command sorts the ports by direction and then by full name.

```
pt_shell> sort_collection [get_ports *] \\
{direction full_name}
{"in1", "in2", "out1", "out2"}
```

Implicit Query of Collections

In many applications, commands that create collections implicitly query the collection when the command is used at the command line. Consider the following examples from PrimeTime:

```
pt_shell> set_input_delay 3.0 [get_ports in*]
1
pt_shell> get_ports in*
{"in0", "in1", "in2"}
pt_shell> query_objects -verbose [get_ports in*]
{"port:in0", "port:in1", "port:in2"}
pt_shell> set iports [get_ports in*]
{"in0", "in1", "in2"}
```

In the first example, the *get_ports* command creates a collection of ports that is passed to the *set_input_delay* command. This collection is not the result of the primary command (*set_input_delay*), and as soon as the primary command completes, the collection is destroyed. The second example shows how a command that creates a collection automatically queries the collection when that command is used as a primary command. The third example shows the verbose feature of the *query_objects* command, which is not available with an implicit query. Finally, the fourth example sets the variable iports to the result of the *get_ports* command. Only in the final example does the collection persist to future commands until iports is overwritten, unset, or goes out of scope.

---

color_macro_pins

Colors the pins of the macro block using ICV with colored runset.

Syntax

status *color_macro_pins*

Description

The *color_macro_pins* command assigns the colors to pins of instantiated macro blocks in hierarchical design having double pattern process layers. The color to a pin is assigned on the basis of track colors, though there may not be 100% alignment possible.

This command invokes the IC Validator tool with a colored runset either on the NDM lib or GDS to assign the colors to pins based on track colors.

This command supports the following inputs - GDS and NDM Lib. There are different app options required to be set based on the given input. In case of GDS input flow, parameters such as technology file, layer map file, track offset, preferred routing direction, rule type, track color preference and others can be specified through app options.

All the app options for this command are specifed under the category of signoff.color_macro.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example runs the *color_macro_pins* command on the current block using the TSMC 16nm node colored runset:

```
prompt> set_app_options -name signoff.color_macro.rule_type \\
   -value "tsmc16"
prompt> color_macro_pins
```

The following example shows the color attribute, *mask_constraint*, set on the pin shapes:

```
prompt> get_attribute [get_shapes -of_objects [get_port <port-name>]] \\
   mask_constraint
```

---

commit_blackbox_timing

Commits black box timing information specified by *create_blackbox_constraint*, *create_blackbox_delay*, and other black box timing commands.

Syntax

```
status commit_blackbox_timing
[-convert_placement_abstract true | false]
```

Arguments

`-convert_placement_abstract true | false`

Converts the placement abstract to a timing abstract with black box timing (BBT) data. Specify *-convert_placement_abstract false* to prevent the command from overwriting an existing placement abstract view. By default, this option is true and the command overwrites the existing abstract view of the design and replaces it with a compact timing abstract view with black box timing.

Description

This command saves the black box timing information you created with the *create_blackbox_constraint*, *create_blackbox_delay*, and other black box timing commands. The command creates or updates the abstract view of the current block to include the black box timing data.

Feedback

Examples

The following example creates an abstract view, with black box timing information, for the current design.

```
prompt> create_clock -period 10 -name main_clock [get_ports Clk]
prompt> set_blackbox_clock_port [get_ports Clk]
prompt> create_blackbox_clock_network_delay -value 0.5 [get_ports Clk]
prompt> create_blackbox_load_type -lib_cell buf0 loadType1
prompt> create_blackbox_drive_type -lib_cell buf8 driveType1
prompt> set_blackbox_port_load -type loadType1 [all_inputs]
prompt> set_blackbox_port_drive -type driveType1 [all_outputs]
prompt> create_blackbox_delay -rise_from Clk -to [all_outputs] -clock
 main_clock -value 0.3
prompt> create_blackbox_constraint -from Clk -edge rise -to [all_inputs]
 \\
        -clock main_clock -value 0.3
prompt> commit_blackbox_timing
```

---

commit_block

Creates a separate physical hierarchy design from a logical hierarchical cell.

Syntax

```
collection commit_block
[-library library]
[-cells cells]
```

Feedback

```
[-verbose]
modules
```

Data Types

```
library  string
cells    collection
modules  collection
```

Arguments

`-library` *library*

Specifies the library in which to create the new design. By default, the current design library is used.

`-verbose`

Reports additional debugging information.

`-cells` *cells*

Specifies a collection of cells, The *-cells* and *modules* are mutually exclusive, you need to specify one.

modules

Specifies the name of a logic cell to commit into a physical block. You can specify a module name or a collection of module names. The *-cells* and *modules* are mutually exclusive, you need to specify one.

Description

This command commits a logical hierarchy cell to a physical hierarchy block and returns a collection containing the committed cell.

The shape of the committed block is dependent upon whether cell hierarchy type is "module" or "module boundary". If it is "module", there is no physical boundary by which to determine a physical boundary of a resulting block. In this case, the command will create a default square boundary based upon criteria such as the number of leaf-cells/blocks in the module. Also in this case, the *commit_block* command will not attempt to place member cells within the committed reference block since it has no certain origin by which to place child cells inside the reference block. So in this scenario, the cells in the reference block will be unplaced. Also in this scenario, the instance of the block will be placed outside the top block core boundary.

If the module cell hierarchy type is "module boundary" and you have placed the module boundary in the core area, then the command has what it needs to create a block boundary, and an origin that it can use to place the cells in the reference block, and will do so. In this scenario, the resulting block instance will be placed based upon the determined origin of the module boundary associated with the module instance. In any case, regardless of where the module boundary is placed, the resulting placement of

Feedback

cells in the committed block will show the exact same geometric relationship to the block origin in the reference block as the member cell instances of the module instance has to the lower left corner of the module boundary before *commit_block*. This is because *commit_blocks* merely transforms the relative locations from the top to the block based upon the cell instance's location relative to the module boundary lower-left corner location.

If you doesn't specify module names and use *-cells* to specify a reference cell, the command will commit its module and use the boundary of the specified cell for all MIB instances.

The *commit_block* command propagates routing, move bounds, relative placement groups and other logical-based elements to the block level during the commit process. All routing associated with module-owned nets is propagated automatically to the block. All move bounds that are enclosed by the module boundary, and whose cells are only those that belong to the module being committed, are propagated to the block. All group bounds whose cell members exclusively belong to the module instance are also propagated automatically to the block. All relative placement groups that are enclosed by the module boundary, and whose cells exclusively belonging to the module being committed, are propagated to the block.

Also as part of the commit process, certain overlap-based propagations occur. This includes placement blockages and route guides that are completely within the module boundary of the module being committed. If there is no module boundary, then placement blockages and route guides are not propagated.

If the module type is "module" (or normal), and the module instance has multiple fixed placed instances, the command auto-derives a bounding box defined by these instances, and creates a block boundary. The boundary is based on the bounding box and the block origin is placed at the lower-left corner of the bounding box, with R0 orientation. If there are multiple instances of this module with fixed placed instances, the command chooses a reference among the fixed-placed child instance of the module instance and creates and places the first block instance as mentioned above.

For each subsequent instance, the fixed-placed reference instance is used to determine the location and orientation the remaining MIB block instances. You must carefully confirm that ALL fixed-placed child instances are exactly consistent with each of the other MIB module instances' child instances. If the instances are not consistent, the results of committing the MIB instances are very unpredictable. The command DOES NOT pre-check that all MIB module instances are consistently placed. You must check the placement consistency before using the *commit_block* command to auto-infer shapes and orientations of MIB committed block instances.

If an instance of the committed block results in placement over any site arrays, copies of these site arrays are created within the block based upon that overlap with top-level site arrays. If there is no overlap (type is "module") with any site array after commit, then a default site array is still created in the block, based upon the top default site array, but this site array is not guaranteed to be aligned with the top site array because the committed

Feedback

block instance does not overlap the top default site array. This is generally not an issue because in this situation, it is normally the case that subsequent flow steps will involve block shaping, which will propagate the default site array after the block has been placed and shaped, and at that point the block-level site array should then be in alignment.

By default, a hard inner keepout margin is created in the committed block. The committed block's default inner keepout is equal to one row height, and its default outer keepout is equal to twice of the minimal wire track width.

The committed block saif map will be generated using the block level saif map information in the parent hierarchy, if the saif map information is present in the parent block.

Use the following application options to specify how the inner keepout is created:

plan.commit.inner_keepout_margin hard | soft | none

user_unit_distance must include unit # appended to the distance value
plan.commit.inner_keepout_margin_size *user_unit_distance*

plan.commit.outer_keepout_margin hard | soft | none

user_unit_distance must include unit # appended to the distance value
plan.commit.outer_keepout_margin_size *user_unit_distance*

The *commit_block* command will implcitly create and load saif_map for the newly created commit block if the parent block has saif_map data.

examples:

set_app_options -list {plan.commit.inner_keepout_margin hard}

set_app_options -list {plan.commit.inner_keepout_margin_size 0.3um}

set_app_options -list {plan.commit.outer_keepout_margin hard}

set_app_options -list {plan.commit.outer_keepout_margin_size 0.1um}

set_app_options -list {plan.commit.inner_keepout_margin none}

set_app_options -list {plan.commit.outer_keepout_margin none}

Note that application option values are persistent in the database.

Note that the *commit_block* command fails under the following conditions:

- The specified library is not the design library or one of the current reference libraries.
- The module does not exist or is not a hierarchical logic cell.
- The library already contains a design with the name of the new design to be created.

Feedback

Examples

The following example commits the cells that are instantiated from module A to blocks.

```
prompt> commit_block A
```

---

commit_dft_isolation

Commit all existing set_dft_isolation settings post insert_dft.

Syntax

status *commit_dft_isolation*

Description

Committed set_dft_isolation settings will be converted into their equivalent "set_isolation -update ..." UPF command setting applying to the corresponding DFT signals.

Examples

The following example commits the set_dft_isolation settings of the design.

```
prompt> commit_dft_isolation
```

commit_pseudo_bumps

Convert a pseudo bump of a bump region to its real physical implementation with either a bump cell, a bond pad, a bump cluster or other 3DIC related physical objects.

Syntax

collection *commit_pseudo_bumps*

```
[-prefix prefix]
[-region_names region_names]
[-target_dies target_dies]
[-probe_bumps probe bumps]
[-dummy_bumps dummy bumps]
[-bumps bumps]
[-map map]
[-tsv_map map]
[-prefix_style type]
[-propagate_user_attributes]
[-force]
```

Data Types

```
prefix              string
region_names        list
target_die          list
probe bumps         list
dummy bumps         list
probe bumps         list
map                 string
type                string
```

Arguments

`-prefix prefix`

Specifies a name prefix for the objects generated.

Feedback

`-region_names` *region_names*

Specifies a list of regions to process. By default, all bump regions will be processed.

`-target_dies` *target_die*

Specifies a list of dies to process. By default, all dies will be processed.

`-probe_bumps` *probe bumps*

Specifies a two-level nested list of reference cells to be created when the pseudo bump is marked as probe bump. This option cannot be specified with the *-map* option.

`-dummy_bumps` *dummy bumps*

Specifies a two-level nested list of reference cells to be created when the pseudo bump is marked as dummy bump. This option cannot be specified with the *-map* option.

`-bumps` *bumps*

Specifies a two-level nested list of reference cells to be created when the pseudo bump is neither probe nor dummy bump. This option cannot be specified with the *-map* option.

`-map` *map*

Specifies a priority mapping table to convert a pseudo bump to a lib_cell. If a pseudo bump attribute matches the value specified, the corresponding lib_cell will be used. The default entry specifies the default_lib_cell to be used when other matches is found. The following attributes are currently supported {is_probe_pad, is_dummy, is_destructible, radius, orientation, net.net_type, user attribute of pseudo bump}. The net.type attribute allows {power, ground, signal} values. By changing the ordering of entries, a bump with multiple matches can be mapped to different cells based on the list's priority. The map must be provided by the user. No default map available. This option cannot be specified with the *-probe_bumps*, *-dummy_bumps* and *-bumps* option.

`-tsv_map`

Specifies a priority mapping table to convert a pseudo tsv to a lib_cell or via_def. If a pseudo tsv attribute matches the value specified, the corresponding lib_cell or via_def will be used. The default entry specifies the default_lib_cell or default_via_def to be used when other matches is not found. By changing the ordering of entries, a tsv with multiple matches can be mapped to different cells based on the list's priority. The tsv_map must be provided by the user. No default map available. This is a optional command option.

Feedback

`-prefix_style`

Specifies the prefix style, use assigned net, port or corresponding region name as the prefix of new committed bump/bond pad/tsv. Values: *net*, *port* and *region*. net: the name of net assigned to associated psuedo bump is used as the prefix of new object. port: the name of port assigned to associated psuedo bump is used as the prefix of new object. region: the name of corresponding region of psuedo bump is used as the prefix of new object.

`-propagate_user_attributes`

Propagate user attributes from pseudo bumps/tsvs to coressponding committed bump cells/tsvs/bond pads/bump clusters.

`-force`

Specifies whether to commit bump clusters if there are overlaps.

Description

Convert a pseudo bump of a bump region to its real physical implementation with either a bump cell, a bond pad, a bump cluster or other 3DIC related physical objects. The real objects are associated to the region so that they form an edit_group that can be moved together. The objects are logically connected to nets based on the net assignment of the pseudo bump. The physical implementation is based on the priority mapping specified by -map, or one of the lists specified in "-probe_bumps", "-dummy_bumps" or "-bumps option".

Examples

The following example commits the region "bump_region_1" to its real physical implementation with prefix "synopsys_".

```
method 1:
prompt> commit_pseudo_bumps hbl_ref -prefix synopsys -region_names
 {bump_region_1} -bumps {{hb_ref_1 PAD22APBT}}
method 2:
prompt> define_user_attribute -classes pseudo_bump -type boolean -name
 testBool
prompt> define_user_attribute -classes pseudo_bump -type int -name
 testInt
prompt> define_user_attribute -classes pseudo_bump -type float -name
 testFloat
prompt> define_user_attribute -classes pseudo_bump -type double -name
 testDouble
prompt> define_user_attribute -classes pseudo_bump -type string -name
 testString
prompt> commit_pseudo_bumps  -prefix synopsys
                             -region_names {bump_region_1}
                             -map {{is_dummy true hbl_ref_4}
                                  {is_probe_pad true hbl_ref_5}
```

Feedback

```
{testBool true hbl_ref_6}
{testInt 888 hbl_ref_7}
{testFloat 3.414 hbl_ref_8}
{testDouble 1.732 hbl_ref_9}
{testString snps hbl_ref_10}
{net.net_type ground PAD100M1BI}
{net.net_type power TSV4BUMP8}
{radius 30.0 PAD200APBI}
{default PDDW12SDGZ_G} }
```

---

commit_pseudo_tsvs

Convert a pseudo tsv of a bump region to its real physical implementation with either a tsv, a bump cluster or other 3DIC related physical objects.

Syntax

collection *commit_pseudo_tsvs*

```
[-prefix prefix]
[-region_names region_names]
[-target_dies target_dies]
-tsv_map map
[-bump_map map]
[-prefix_style type]
[-propagate_user_attributes]
[-force]
```

Data Types

prefix	string
region_names	list
target_die	list
map	string
type	string

Arguments

`-prefix prefix`

Specifies a name prefix for the objects generated.

Feedback

`-region_names` *region_names*

Specifies a list of regions to process. By default, all bump regions will be processed.

`-target_dies` *target_die*

Specifies a list of dies to process. By default, all dies will be processed.

`-tsv_map` *map*

Specifies a priority mapping table to convert a pseudo tsv to a lib_cell or via_def. If a pseudo tsv attribute matches the value specified, the corresponding lib_cell or via_def will be used. The default entry specifies the default_lib_cell or default_via_def to be used when other matches is not found. By changing the ordering of entries, a tsv with multiple matches can be mapped to different cells based on the list's priority. The tsv_map must be provided by the user. No default map available. This is a required command option.

`-bump_map` *map*

Specifies a priority mapping table to convert a pseudo bump to a lib_cell. If a pseudo bump attribute matches the value specified, the corresponding lib_cell will be used. The default entry specifies the default_lib_cell to be used when other matches is found. The following attributes are currently supported {is_probe_pad, is_dummy, is_destructible, radius, orientation, net.net_type, user attribute of pseudo bump}. The net.type attribute allows {power, ground, signal} values. By changing the ordering of entries, a bump with multiple matches can be mapped to different cells based on the list's priority. The map must be provided by the user. No default map available.

`-prefix_style`

Specifies the prefix style, use assigned net or port name in the associated pseudo bump as the prefix of new committed tsv. Values: *net* and *port*. net: the name of net assigned to associated psuedo bump is used as the prefix of new object. port: the name of port assigned to associated psuedo bump is used as the prefix of new object.

`-propagate_user_attributes`

Propagate user attributes from pseudo bumps/tsvs to coressponding committed bump cells/tsvs/bond pads/bump clusters.

`-force`

Specifies whether to commit tsvs or tsv clusters if there are overlaps.

Description

Convert a pseudo tsv of a bump region to its real physical implementation with either a tsv, a bump cluster or other 3DIC related physical objects. The real objects are associated

Feedback

to the region so that they form an edit_group that can be moved together. The physical implementation is based on the priority mapping specified by -tsv_map.

Examples

The following example commits the region "bump_region_1" to its real physical implementation with prefix "synopsys_".

```
prompt> create_bump_region_pattern -pitch_x 300 -pitch_y 300 -bump_shape
 square -bump_radius 30 -name pattern
prompt> create_pseudo_tsv_def -diameter 10 -num_cols 1 -num_rows 1
 -keepout 5 -spacing 1 -name ptDef
prompt> create_bump_region -pattern pattern -boundary {{0 0} {2500 2500}}
 -name bump_region_1 -net_pattern {VSS VDD} -tsv_pattern {{{ptDef 5 5}}}

---

commit_secondary_pg_placement_constraints

commit all secondary pg constraints

Syntax

status *commit_secondary_pg_placement_constraints*

Feedback

```
[-commit_subblocks]
```

Arguments

`-commit_subblocks`

This is an optional option. In case the design has linked physical hierarchies, commit_secondary_pg_placement_constraints will go to each of the linked subblocks to check and make sure they have secondary pg constraints committed and up to date if there are indeed secondary pg constraints in those subblocks. Without this option specified and if there is linked subblocks being uncommitted in terms of secondary pg constraints, commit_secondary_pg_placement_constraints will error. With this option specified, commit_secondary_pg_placement_constraints will automatically commit secondary pg constraints in each subblocks if their secondary pg constraints have not be committed or not up to date.

Description

After all secondary pg constraints are created, users need to issue this command so that the tool can process all the constraints and internally generate the physical regions which will allow dual rail cells to be inserted in.

If the floorplan, UPF, secondary supply straps or secondary pg constraints are changed or removed, users also need to issue this command so that the tool can process all the remain constraints and internally regenerate or remove any special physical regions created due to the prior existed secondary pg constraints.

Examples

The following example commit all secondary pg constraint

```
prompt> commit_secondary_pg_placement_constraints
```

See Also

- create_secondary_pg_placement_constraints
- remove_secondary_pg_placement_constraints
- report_secondary_pg_placement_constraints

---

commit_upf

Commits the UPF constraints of the design.

Syntax

status *commit_upf*

Feedback

```
[-skip_resolve_pg_net]
```

Arguments

`-skip_resolve_pg_net`

If specified, the command does not resolve potential conflicts between power intent and pg net connections.

Description

This command commits the UPF intent of the design. It indicates that the UPF constraints of the design are finalized and complete.

By default, the command tries to resolve potential conflicts between the power intent and PG net connections. To disable this behavior, set the *mv.upf.auto_resolve_pg_net* application option to *false*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example commits the UPF intent of the design.

```
prompt> commit_upf
```

See Also

- load_upf
- mv.cells.rename_isolation_cell_with_formal_name

---

compare_app_options

Reads and compares application option settings between two tool sessions. Settings data is written to a binary data file by the *write_app_options* command.

Syntax

integer *compare_app_options*

```
-previous_data data_file
-current_data data_file
[-nosplit]
[-value_diffs]
[-csv file_name]
[-metadata]
```

Feedback

Data Types

```
data_file      string
file_name      String. Report contents to this file in CSV format.
```

Arguments

`-previous_data` *`data_file`*

Specifies the file that contains the binary application option settings data. The *data_file* argument can be a local file name or a full path name to the file. The data specified by this option is the previous or original data and is displayed on the left side of the comparison output report.

`-current_data` *`data_file`*

Specifies the file that contains the binary application option settings data. The *data_file* argument can be a local file name or a full path name to the file. The data specified by this option is the current or data to be compared against the original and is displayed on the right side of the comparison output report.

`-nosplit`

Don't split lines if column overflows.

`-value_diffs`

Generate an alternate report which combines all app option value differences into one table.

`-csv` *`file_name`*

Specifies the output CSV file name. The report contents will be output to this file in CSV format. The *file_name* argument can be a local file name or a full path name to the file.

`-metadata`

Add the metadata which includes comment information of compared data to the CSV file.

Description

This command creates a single report with multiple tables reporting these differences for each application option that differs between the two input files:

- Status
- Changes in Default Value
- Changes in Global Value
- Changes in Block Value

Feedback

- Changes in Global status
- Changes in ReadOnly status
- Changes in Deprecated status
- Changes in Persistent status
- Changes in Disabled status
- Changes in Application Variables

The report will also show Added and Removed application options.

- Added application options are in the current data file, but not in the previous_data file
- Removed application options are in the previous data file, but not in the current_data file

The command writes the report to the console. To save the output to a .csv file, you could run the command as follows:

```
compare_app_options \\
    -previous_data file1.data \\
    -current_data file2.data \\
    -csv compare.csv
```

Use the *compare_app_options* command to generate reports such as:

- Application option differences when block A is loaded vs. block B
- Application option differences between different startup Tcl scripts
- Application option differences between different tool releases

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

This example generates the binary application option data files for two tool sessions and compares the files.

```
# In the first tool session
prompt> write_app_options -output app_option_SP1.data

# In the second tool session
prompt> write_app_options -output app_option_SP2.data
prompt> compare_app_options -previous_data app_option_SP1.data \\
   -current_data app_option_SP2.data
```

Feedback

This example writes the binary application option data and shows the differences in application options between design A and design B.

```
# Design A is now the current design
prompt> current_design designA
prompt> write_app_options -output designA.data

# Design B is now the current design
prompt> current_design designB
prompt> write_app_options -output designB.data

# Compare application options
prompt> compare_app_options -previous_data designA.data \\
   -current_data designB.data
```

The following example shows a sample report generated by the *compare_app_options* command.

```
prompt> compare_app_options -previous_data old.data \\
   -current_data new.data

Opened Previous File: old.data
      Total: 1176
      ------ -----
      basic: 1176

Opened Current File: new.data
      Total: 1181
      ------ -----
      basic: 1181

Summary:
-------------------------

Added App Options:
      Total: 10
      ------ -----
      basic: 10

Removed App Options:
      Total: 5
      ------ -----
      basic: 5

Difference Summary:
      Default Value   4
      Block Value     1
      Global          1
      Persistent      1

Differences:
-------------------------

compare_checksum

This utility is for comparing checksums generated by write_checksum.

Feedback

Syntax

status *compare_checksum*

```
-icc2 icc2_checksum_path
-pt pt_checksum_path
```

Data Types

```
icc2_checksum_path       string
pt_checksum_path         string
```

Arguments

`-icc2 icc2_checksum_path`

Specifies the directory that contains the IC Compiler II checksums to compare. This option is required.

`-pt pt_checksum_path`

Specifies the directory that contains the PrimeTime checksums to compare. This option is required.

Description

The *compare_checksum* compares checksums generated by write_checksum of input consistency checker.

The command would run in the background. The output of the command is redirected to

- `correlation.out`

The compare checksum reports files will be

- `DesignChecksumSummary.rpt`
- `DesignChecksumDetail.rpt`
- `LibraryChecksumSummary.rpt`
- `LibraryChecksumDetail.rpt`
- `ParasiticsChecksumSummary.rpt`
- `ParasiticsChecksumDetail.rpt`
- `ConstraintsCheckerSummary.rpt`
- `ConstraintsCheckerDetail.rpt`

By default, the *write_checksum* command generates all the checksums in the current directory.

Examples

The following example generates compare checksum reports in the current directory. The IC Compiler II checksums are in ./icc2/scenario and the PrimeTime checksums are in ./pt.

```
prompt> compare_checksum -icc2 ./icc2/scenario1 -pt ./pt
```

Feedback

See Also

- write_checksum

---

compare_collections

Compares the contents of two collections. If the same objects are in both collections, the result is "0" (like string compare). If they are different, the result is nonzero. The order of the objects can optionally be considered.

Syntax

int *compare_collections*

```
[-order_dependent]
collection1
collection2
```

Data Types

collection1	collection
collection2	collection

Arguments

`-order_dependent`

Indicates that the order of the objects is to be considered; that is, the collections are considered to be different if the objects are ordered differently.

collection1

Specifies the base collection for the comparison. The empty string (the empty collection) is a legal value for the *collection1* argument.

collection2

Specifies the collection with which to compare to *collection1*. The empty string (the empty collection) is a legal value for the *collection2* argument.

Description

The *compare_collections* command is used to compare the contents of two collections. By default, the order of the objects does not matter, so that a collection of cells u1 and u2 is the same as a collection of the cells u2 and u1. By using the *-order_dependent* option, the order of the objects is considered.

Either or both of the collections can be the empty string (the empty collection). If two empty collections are compared, the comparison succeeds (that is, *compare_collections* considers them identical), and the result is "0".

Feedback

Examples

The following example from PrimeTime shows a variety of comparisons. Note that a result of "0" from *compare_collections* indicates success. Any other result indicates failure.

```
pt_shell> compare_collections [get_cells *] [get_cells *]
0
pt_shell> set c1 [get_cells {u1 u2}]
{"u1", "u2"}
pt_shell> set c2 [get_cells {u2 u1}]
{"u2", "u1"}
pt_shell> set c3 [get_cells {u2 u4 u6}]
{"u2", "u4", "u6"}
pt_shell> compare_collections $c1 $c2
0
pt_shell> compare_collections $c1 $c2 -order_dependent
-1
pt_shell> compare_collections $c1 $c3
-1
```

The following example builds on the previous example by showing how empty collections are compared.

```
pt_shell> set c4 ""
pt_shell> compare_collections $c1 $c4
-1
pt_shell> compare_collections $c4 $c4
0
```

See Also

- collections

---

compare_design_io

Compares two versions of a design CSV files for any bump floorplan changes.

Syntax

string *compare_design_io*

```
[-golden       CSV_File_Name]
[-v2           CSV_File_Name]
[-output       CSV_File_Name]
[-show]

CSV_File_Name          String
```

Feedback

Arguments

`-golden` *CSV_FILE_Name*

The primary golden design I/O elements CSV file name to compare to.

`-v2` *CSV_FILE_Name*

The modified version of the golden design I/O elements CSV file name to compare against.

`-output` *CSV_FILE_Name*

The name used for the CSV file with the differences in the I/O elements between the two input CSV files. The default name is *bump_eco_delta*.

`-show`

Show the difference in a UserTable in the GUI. The output file is not saved to the hard disk until it is saved in the GUI. The name of the UserTable is the name in the *-output* option or the default name.

Description

This command enables you to compare two versions of a design I/O elements CSV files and either generate a difference CSV file, or view and analyze the difference in a UserTable GUI view.

Examples

The following example takes two design I/O elements CSV files and generates a difference CSV file.

```
      compare_design_io -golden myIoDesign.csv -v2 myIoDesign2.csv \\
  -output myIoDiff.csv
```

See Also

- write_design_io
- read_design_io

---

compare_floorplans

Writes a report that lists any differences in objects and their locations between the current design and floorplan information for another design written by the *write_floorplan* command.

Feedback

Syntax

int *compare_floorplans*

```
[-input dir_name]
[-verbosity minimum | low | high]
[-top_level_only]
```

Data Types

```
dir_name string
```

Arguments

`-input dir_name`

Specifies the name of the directory under which the file *floorplan_compare_data.txt* is located. The default is *./floorplan*. The command writes an error message and exits if the directory does not exist, or if the file is missing.

`-verbosity minimum | low | high`

Determines the level of comparison detail to report. The *minimum* argument prints the number of differences for each object type. The *low* argument prints up to five examples for each object type. The *high* argument prints up to 1000 differences of each type. By default, the level is minimum.

`-top_level_only`

Compares only top-level objects and skip comparison for lower-level objects.

Description

The *compare_floorplans* command creates a report containing a list of objects that are either in *floorplan_compare_data.txt* file but not in the design database, or in the design database but not in *floorplan_compare_data.txt*. The object types that are considered are macros and pins. Feedthrough pins are not considered. The command creates a file named *compare_output*, in the current directory, that creates lists of new objects that are in the existing in database but not in the file. For example:

```
set _new_macros [get_cells { macro1_name macro2_name ...}]
set _new_ports {...}
```

For objects in the *floorplan_compare_data.txt* file but not in the database, the command outputs names and locations or boundaries in the same file. The command outputs two levels, for example, pins and macros at the top level and inside blocks. The command skips the output for the third level and beyond.

Note that the *floorplan_compare_data.txt* file is generated by the *write_floorplan* command. The *compare_floorplans* command is typical used to compare different versions of the same design. For example, begin by running the *write_floorplan* command on

Feedback

one version of the design. Then, load the new version and use the *compare_floorplans* command to determine if any differences exist between the two versions.

This command returns 1 on success, 0 otherwise.

Examples

The following example writes a report based on comparing the current design with the *floorplan_compare_data.txt* file in the script directory.

```
prompt> compare_floorplans -input script
```

The following example prints more detailed information, but outputs data related to the top-level only.

```
prompt> compare_floorplans -verbosity high -top_level_only
```

See Also

- write_floorplan

---

compare_libraries

Compare the content and analysis results between two libraries.

Syntax

status *compare_libraries*

```
-ref_lib library_object
-target_lib library_object
-ref_lib_analysis analysis_name
-target_lib_analysis analysis_name
[-all | -inv_buf | -combinational | -sequential | -registers | -latch |
 -families family_name_string_list | -custom_pairs file_name]
[-attributes attribute_name_string_list]
[-lex_attr_mapping file_name]
[-ref_lib_opcond opcond_name_string | -ref_lib_ppvt ppvt_label_string]
[-target_lib_opcond opcond_name_string | -target_lib_ppvt
 string ppvt_label_string]
[-slew_point slew_value | -slew_index slew_index\
[-load_point load_value | -load_index load_index\
[-output_comparison_pairs file_name]
[-verbose]
[-show_absolute_values]
[-significant_digits digits]
[-plot]
[-plot_title plot_title_string]
```

Feedback

Data Types

library_object	library-object
analysis_name	string
family_name_string_list	list-of-strings
attribute_name_string_list	list-of-strings
file_name	string
opcond_name_string	string
ppvt_label_string	string
slew_value	float
load_value	float
slew_index	integer
load_index	integer
plot_title_string	string

Arguments

`-ref_lib` *library_object*

The reference library as the comparison baseline.

`-target_lib` *library_object*

The target library to be compared against the reference library. This is allowed be the same to the reference library for comparing the properties under different operating conditions.

`-ref_lib_analysis` *analysis_name*

The analysis name which the reference library was analyzed.

`-target_lib_analysis` *analysis_name*

The analysis name which the target library was analyzed.

`-all`

Compare all library cells.

`-inv_buf`

Compare all inverters and buffers.

`-combinational`

Compare all combinational cells.

`-sequential`

Compare all sequential cells.

`-registers`

Compare all register cells (Flip-Flops).

Feedback

`-latch`

Compare all latch cells.

`-families` *`family_name_string_list`*

Compare all library cells in the specified library cell families.

`-custom_pairs` *`file_name`*

Compare the library cell pairs as defined in the file.

`-lex_attr_mapping` *`file_name`*

The lexical attribute values mapping relationship between the reference and the target libraries.

`-attributes` *`attribute_name_string_list`*

The attributes to be compared. The allowed attributes are {area, avg_pin_cap, avgsl_rise_drive, avgsl_fall_drive, avgsl_rise_delay, avgsl_fall_delay, avgsl_rise_setup, avgsl_fall_setup, avgsl_rise_hold, avgsl_fall_hold, avgsl_rise_ckq, avgsl_fall_ckq, avgsl_rise_bht, avgsl_fall_bht, leakage, internal_power, switch_power, dynamic_power}. If this argument is not provided, by default all the attributes will be compared and reported.

`-ref_lib_opcond` *`opcond_name_string`*

The operating condition of the reference library to be compared, specified by operating condition name. It must be analyzed by *run_library_analysis*.

`-target_lib_opcond` *`opcond_name_string`*

The operating condition of the target library to be compared, specified by operating condition name. It must be analyzed by *run_library_analysis*.

`-ref_lib_ppvt` *`ppvt_label_string`*

The operating condition of the reference library to be compared, specified with the format {Process Label, Process, Voltage, Temperature}. It must be analyzed by *run_library_analysis*. If the Process Label is not defined in the library thus it is empty, use the reserved keyword (none). Examples: {Typical, 1.0, 0.85, 25}, {(none), 1.0, 0.85, 25}

`-target_lib_ppvt` *`ppvt_label_string`*

The operating condition of the target library to be compared, specified with the format {Process Label, Process, Voltage, Temperature}. It must be analyzed by *run_library_analysis*. If the Process Label is not defined in the library thus it is empty, use the reserved keyword (none). Examples: {Typical, 1.0, 0.85, 25}, {(none), 1.0, 0.85, 25}

Feedback

`-slew_point` *`slew_value`*

The input slew condition of this comparison, specified by the absolute value. This slew point must be analyzed by *run_library_analysis*.

`-slew_index` *`slew_index`*

The input slew condition of this comparison, specified by the index of the slew points given to *run_library_analysis*.

`-load_point` *`load_value`*

The output load condition of this comparison, specified by the absolute value. This output load must be analyzed by *run_library_analysis*.

`-load_index` *`load_index`*

The output load condition of this comparison, specified by the index of the output load given to *run_library_analysis*.

`-output_comparison_pairs` *`file_name`*

To write out a file listing the library cell comparison pairs. This file is written in the file format taken by the argument *-custom_pairs*.

`-verbose`

Report the results in verbose mode, with more information.

`-show_absolute_values`

In verbose mode, report the reference and the target library cells' absolute values in addition to the change percentage. Verbose mode will be automatically enabled when this option is specified.

`-significant_digits` *`digits`*

Specifies the number of digits to the right of the decimal point to report. This applies to absolute values and does not apply to the change percentage numbers. The allowed values are from 5 to 13. The default is 5.

`-plot`

Create plots on GUI for the comparison results. Use *start_gui* to initialize GUI before executing the command with this argument.

`-plot_title` *`plot_title_string`*

The title of the plots created on GUI.

Description

This command allows users to compare the analysis results and contents between two libraries. In addition, the interested operating conditions can be specified individually to

Feedback

the reference library and the target library. Users can also compare the same library under different operating conditions.

Library cells in the reference library and the target library are compared on each attributes. A report showing the comparison results will be given. Plots can be created on GUI by specifying *-plot*. Use *start_gui* to initialize GUI before executing the command with *-plot*.

Before executing this command, the user needs to run *run_library_analysis* to analyze the libraries. The reference library is the baseline for comparison; the results of target library is compared against the reference library. A change +/- % will be given for each attribute of each library cell, 0% means the results in the reference library and the target library are the same. A +/- X% change means the number in the target library is X% larger/smaller than the number in the reference library.

This command iterates each library cell from the reference library (reference library cell), and searches for a matched library cell from the target library (target library cell). These two library cells forms a matching pair {reference library cell, target library cell}. The comparisons are later performed on each matching pair.

The matching is based on library cell names. By default, the reference & target library cells' full names are used as the matching condition. This is useful when two libraries with same library cell naming are compared. For libraries with very similar but not exactly matched cell namings, the matching method can be adjusted to use lexical attributes extracted by lexical classification, instead of using the full cell name.

To use lexical attributes, the reference and target libraries must be lexical classified by *classify_lib_cell_attributes*. These lexical attributes *lexical_cell_prefix_name*, *lexical_drive1_name*, and *lexical_drive2_name* are required to be matched.

If the expected values of the same lexical attribute are different between the reference and the target libraries (e.g. HVT vs. HighVt), a mapping file can be provided via *-lex_attr_mapping* to guide the tool knowing what values should be considered as equivalent.

The lexical attribute mapping file format, three fields separated by space:

```
A_Lexical_Attribute  Value_in_Ref_Lib  Valie_in_Target_Lib

E.g.
    lexical_cell_prefix_name           ND2  nand2
    lexical_device_threshold_voltage   HVT  HighVt
    lexical_device_threshold_voltage   LVT  LowVt
```

Each line defines a mapping relationship. For the above example, when the tool checks for the lexical attributes *lexical_cell_prefix_name* of a reference and a target library cell, the value nand2 seen in the target library cell will be considered as equivalent to the value ND2 seen in the reference library cell. Same to the defined mapping relationships on *lexical_device_threshold_voltage*, the tools will consider HVT = HighVt, LVT = LowVt, between the reference and the target library cells.

Feedback

The users may manually define the interested library cell comparison pairs with *-custom_pairs*. The tool will directly compare those user-defined pairs instead of automatically searching for the matching pairs.

The file format for library cell pair definitions, two fields separated by space, library names are not required:

```
A_Cell_in_Ref_Lib   A_Cell_in_Target_Lib

E.g.
    INVD1    inv_x1
    ND2D4    nand2_x4
    DFFD1    dff_x1
```

These app options are available for controlling the matching method to be used for constructing matching pairs.

```
Matching by full library cell name:

    libra.complib.match_full_cell_name (Default: True)

Matching by lexical attributes, the above
 libra.complib.match_full_cell_name needs to be set to False.

    True means the attribute needs to be matched.
    If a lexical attribute is allowed to be different, set the
 corresponded app-option to false.

    libra.complib.match_lexical_cell_height
 (Default: True)
    libra.complib.match_lexical_cell_tile_width
 (Default: True)
    libra.complib.match_lexical_circuit_clockgate
 (Default: True)
    libra.complib.match_lexical_circuit_device_sizing_variant
 (Default: True)
    libra.complib.match_lexical_circuit_eco
 (Default: True)
    libra.complib.match_lexical_circuit_layout_density_variant
 (Default: True)
    libra.complib.match_lexical_circuit_layout_variant_1
 (Default: True)
    libra.complib.match_lexical_circuit_layout_variant_2
 (Default: True)
    libra.complib.match_lexical_circuit_multibit
 (Default: True)
    libra.complib.match_lexical_circuit_topology_variant
 (Default: True)
    libra.complib.match_lexical_device_channel_length
 (Default: True)
    libra.complib.match_lexical_device_threshold_voltage
 (Default: True)
```

Feedback

```
   libra.complib.match_lexical_device_type
(Default: True)
   libra.complib.match_lexical_electrical_delay_opt_variant
(Default: True)
   libra.complib.match_lexical_electrical_hold_opt_variant
(Default: True)
   libra.complib.match_lexical_electrical_property_variant
(Default: True)
   libra.complib.match_lexical_electrical_setup_opt_variant
(Default: True)
   libra.complib.match_lexical_electrical_slew_opt_variant
(Default: True)
   libra.complib.match_lexical_electrical_symmetry_variant
(Default: True)
   libra.complib.match_lexical_electrical_timing_arc_variant
(Default: True)
   libra.complib.match_lexical_well_substrate_bias_architecture
(Default: True)
   libra.complib.match_lexical_userdef_property_1
(Default: True)
   libra.complib.match_lexical_userdef_property_2
(Default: True)
   libra.complib.match_lexical_userdef_property_3
(Default: True)
```

Matching method configuration example 1. The library cell names are exactly matched.

```
Library cells in the reference library Lib1:

    INVD1 INVD2 NAND2D1 NAND2D2 FFD1 FFD4

Library cells in the target library Lib2:

    INVD1 INVD2 NAND2D1 NAND2D2 FFD1 FFD4

The constructed matching pairs, no additional app-option setting is
 required.

    {Lib1/INVD1   Lib2/INVD1}
    {Lib1/INVD2   Lib2/INVD2}
    {Lib1/NAND2D1 Lib2/NAND2D1}
    {Lib1/NAND2D2 Lib2/NAND2D2}
    {Lib1/FFD1    Lib2/FFD1}
    {Lib1/FFD4    Lib2/FFD4}
```

Matching method configuration example 2. The library cell names are very similar, but not exactly the same.

```
Library cells in the reference library Lib1:

    INVD1 INVD2 NAND2D1 NAND2D2 FFD1 FFD4

Library cells in the target library Lib2:
```

Feedback

```
    INVD1HVT INVD2HVT NAND2D1HVT NAND2D2HVT FFD1HVT FFD4HVT

The lexical classification must be successfully executed on both
 libraries.

    Lib1/INVD1:

        lexical_cell_prefix_name   =  INV
        lexical_drive1_name        =  D1

    Lib2/INVD1HVT:

        lexical_cell_prefix_name          =  INV
        lexical_drive1_name               =  D1
        lexical_device_threshold_voltage  =  HVT

The matching method can be configured in this way to construct proper
 matching pairs.

    set_app_options -name libra.complib.match_full_cell_name -value false
 -as_user_default
    set_app_options -name
 libra.complib.match_lexical_device_threshold_voltage -value false
 -as_user_default

    {Lib1/INVD1   Lib2/INVD1HVT}
    {Lib1/INVD2   Lib2/INVD2HVT}
    {Lib1/NAND2D1 Lib2/NAND2D1HVT}
    {Lib1/NAND2D2 Lib2/NAND2D2HVT}
    {Lib1/FFD1    Lib2/FFD1HVT}
    {Lib1/FFD4    Lib2/FFD4HVT}
```

Matching method configuration example 3. The library cells have same lexical attributes, but with different values.

```
Library cells in the reference library Lib1:

    HVT_INVD1 HVT_INVD2 HVT_NAND2D1 HVT_NAND2D2 HVT_FFD1 HVT_FFD4

Library cells in the target library Lib2:

    inv_x1_hvt inv_x2_hvt nd2_x1_hvt nd2_x2_hvt reg_x1_hvt reg_x4_hvt

The lexical classification must be successfully executed on both
 libraries.

    Lib1/HVT_NAND2D1:

        lexical_cell_prefix_name          =  NAND2
        lexical_drive1_name               =  D1
        lexical_device_threshold_voltage  =  HVT
```

Feedback

```
    Lib2/nd2_x1_hvt:

        lexical_cell_prefix_name          =  nd2
        lexical_drive1_name               =  x1
        lexical_device_threshold_voltage  =  hvt

A lexical attribute mapping file is needed.

    lexical_cell_prefix_name          INV     inv
    lexical_cell_prefix_name          NAND2   nd2
    lexical_cell_prefix_name          FF      reg
    lexical_drive1_name               D1      x1
    lexical_drive1_name               D2      x2
    lexical_drive1_name               D4      x4
    lexical_device_threshold_voltage  HVT     hvt

The matching method can be configured in this way to construct proper
 matching pairs.

    set_app_options -name libra.complib.match_full_cell_name -value false
 -as_user_default

    {Lib1/HVT_INVD1   Lib2/inv_x1_hvt}
    {Lib1/HVT_INVD2   Lib2/inv_x2_hvt}
    {Lib1/HVT_NAND2D1 Lib2/nd2_x1_hvt}
    {Lib1/HVT_NAND2D2 Lib2/nd2_x2_hvt}
    {Lib1/HVT_FFD1    Lib2/reg_x1_hvt}
    {Lib1/HVT_FFD4    Lib2/reg_x4_hvt}
```

This command iterates each matching pair and compare the interested attributes given by *-attributes*. The supported attributes are:

```
area             : Cell area
avgsl_rise_drive : Averaged drive (rise)
avgsl_fall_drive : Averaged drive (fall)
avgsl_rise_delay : Averaged delay (rise)
avgsl_fall_delay : Averaged delay (fall)
avgsl_rise_setup : Averaged setup time (rise)
avgsl_fall_setup : Averaged setup time (fall)
avgsl_rise_hold  : Averaged hold time (rise)
avgsl_fall_hold  : Averaged hold time (fall)
avgsl_rise_ckq   : Averaged clock-to-q delay (rise)
avgsl_fall_ckq   : Averaged clock-to-q delay (fall)
avgsl_rise_bht   : Averaged black hole time (setup time + clock-to-q
 delay, rise)
avgsl_fall_bht   : Averaged black hole time (setup time + clock-to-q
 delay, fall)
avg_pin_cap      : Averaged input pin capacitance
leakage          : Leakage power
internal_power   : Internal power
switch_power     : Switching power
dynamic_power    : Dynamic power (internal power + switching power)
```

Feedback

```
By default, all the attributes are compared and reported, if -attributes
 is not specified.

Note that the timing attributes are named with prefix avgsl, to better
 indicate the number is calculated
based on the specified (or the default) input slew and output load.
```

The operating conditions can be specified by an operating condition name or a PPVT label {Process Label, Process, Voltage, Temperature}, using arguments *-ref_lib_opcond*, *-target_lib_opcond*, *-ref_lib_ppvt*, or *-target_lib_ppvt*.

The specified conditions must be covered by the analysis performed on the libraries. If an operating condition is not specified, the default operating condition used in the corresponded analysis will be used for comparison.

Different operating conditions can be given to the reference and target libraries, for comparing the libraries under different operating conditions.

The operating conditions of a library can be reported by *report_lib*. Use *report_environments* to check which operating conditions are set to the analysis environment used in the corresponded analysis.

```
To specify this operating condition:

    Name                 Process   Label                Temp      Voltage

 ------------------------------------------------------------------------
---
    TYPICAL0P85V25C      1.00      typical0p85v25c      25.00     0.85

Use:

    -ref_lib_opcond TYPICAL0P85V25C
    -target_lib_opcond TYPICAL0P85V25C

    or

    -ref_lib_ppvt {typical0p85v25c, 1, 0.85, 25}
    -target_lib_ppvt {typical0p85v25c, 1, 0.85, 25}

If the process label is empty, use the keyword (none) to represent an
 empty process label.
For example, {(none), 1, 0.85, 25}
```

The interested input slew and output load can be specified using arguments *-slew_point*, *-slew_index*, *-load_point*, or *-load_index*.

By default, if input slew or output load is not specified, the first input slew or output load used in the corresponded analysis will be used for comparison.

Feedback

The input slew and output load setting of the analysis environment can be reported by *report_environments*.

```
To specify the input slew = 0,1, and output load = 0.05:

    Name       Libset       OPCond             Slew Points     Load
 Points

 ---------------------------------------------------------------------------
    env1       libsetA      TYPICAL0P85V25C    0.1, 0.2        0.01, 0.05

Use:

    -slew_point 0.1
    -load_point 0.05

    or

    -slew_index 0
    -load_index 1
```

The verbose mode can be activated by specifying *-verbose*. Under this mode, more information will be reported, for example:

```
1. Each timing arc of each library cell matching pair, with the absolute
 values and the change %.
2. Each library cell matching pair's comparison results.
```

Plots can be created on GUI, by specifying *-plot*. A plot title can be given by *-plot_title*. A live GUI session is a must for plots creation. Use *start_gui* to initialize a GUi session if it has not been initialized yet.

Some usage examples:

```
## Use the default operating condition, input slew, and output load
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2

## Compare same library, under different operating conditions
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib1] \\
                  -ref_lib_analysis alys1_TT0P8525C -target_lib_analysis
 alys1_FF0P95125C \\
                  -ref_lib_ppvt {TT, 1.0, 0.85, 25} -target_lib_ppvt {FF,
 1.0, 0.95, 125}

## Compare different libraries, under different operating conditions and
 a given slew & load condition
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1_TT0P8525C -target_lib_analysis
 alys2_FF0P95125C \\
                  -ref_lib_ppvt {TT, 1.0, 0.85, 25} -target_lib_ppvt {FF,
 1.0, 0.95, 125} \\
                  -slew_point 0.1 -load_point 0.05
```

Feedback

```
## Compare sequential cells only, on a few interested attributes
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2 \\
                  -sequential \\
                  -attributes {avgsl_rise_ckq avgsl_fall_ckq}

## Compare library cells of library cell families defined for the
 reference library
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2 \\
                  -families {Lib1_initial_INV Lib1_initial_NAND2
 Lib1_initial_FF}

## Compare custom-defined comparison pairs
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2 \\
                  -custom_pairs user_def_pairs.txt

## Use the default operating condition, input slew, and output load, but
 need lexical attribute mapping
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2 \\
                  -lex_attr_mapping lex_attr_mapping.txt

## Report in verbose mode and create plots with a given title
compare_libraries -ref_lib [get_lib Lib1] -target_lib [get_lib Lib2] \\
                  -ref_lib_analysis alys1 -target_lib_analysis alys2 \\
                  -verbose \\
                  -plot -plot_title "Title_1"
```

compare_qor_data

Generates the QoRsum web application and report for viewing or comparing QoR results.

Syntax

status *compare_qor_data*

```
-run_locations run_location_list
[-run_names run_name_list]
```

Feedback

```
[-output output_dir]
[-force]
```

Data Types

```
run_location_list     list
run_name_list         list
output_dir            string
```

Arguments

`-run_locations run_location_list`

Specifies a Tcl list of file system paths to the QoR data written by the *write_qor_data* command. These paths can be one of the following:

- The *-output* directory written by the *write_qor_data* command
- The root directory of a Fusion Platform Methodology (FPM) run
- The *-work_dir* option of an *explore_design* run in the RTL Architect tool

If this option is not specified, the *compare_qor_data* uses ./qor_data as the run location. The command generates a QoRsum report for only this run, and assumes that the default *write_qor_data -output* directory was used.

When using the Fusion Platform Methodology (FPM) flow, the QoR data for each stage is stored in many different subdirectories. There are two ways you can combine all of that data into a single run from the perspective of the QoRsum report.

The first method uses the design or build directory of the FPM run. The build directory is the root directory of the run that includes the ./scripts_global, results for the steps, tasks, and QoR data labels/stages in the entire FPM run.

The second method uses one of the step directories from the FPM run. These directories are the directories immediately below the design or build directory with names, such as 310_fc_syndp or 320_fc_synpnr. One of these directories only collects the QoR data for the tasks and QoR data labels/stages of that particular step.

When using the *explore_design* command in the RTL Architect tool, many different runs are generated in subdirectories under the *explore_design -work_dir* directory. Each of those runs use the *write_qor_data* command to capture QoR results.

Use the same work directory used by the *explore_design* and *report_explore_design_result* commands to gather the results from all runs contained within. You could also use the ./qor_data directory for each of these runs individually. By default, the work directory for an *explore_design* run is named ./work_dir/run_explore_design/design_name.

Feedback

`-run_names` *`run_name_list`*

Specifies a Tcl list of one or more names corresponding to the run data in the *-run_locations* list. The length of this list must match the length of the *-run_locations* list. Use this option to assign descriptive names for each run in the QoRsum report. By default, runs are assigned names such as Run1, Run2, Run3 and so on.

You can also use the *set_qor_data_options -run_name* option during the original run to give the QoR data a name. The name is used by the *compare_qor_data* command when creating the QoRsum report. If the *set_qor_data_options -run_name* and *compare_qor_data -run_names* commands are both used, the latter name takes precedence.

Run names have strict naming restrictions to support various file system and URL naming rules. The allowed characters are numbers (0-9), lowercase letters (a-z), uppercase letters (A-Z), dash (-), underscore (_), period (.), and plus (+).

`-output` *`output_dir`*

Specifies the output directory where the QoRsum web-based report is written. By default, the QoRsum web-based report is written to the ./compare_qor_data directory.

`-force`

Deletes the *-output* directory so the report can be recreated. By default, the QoRsum report is not written out if the *-output* directory already exists.

Description

The *compare_qor_data* command is used to generate the QoRsum web-based report. This report provides an easy-to-use interface for viewing the QoR results of a single run through Synopsys tools, or compare the results of multiple runs. Before using the *compare_qor_data* command, the QoR data must be captured at one or more stages of one or more runs of Synopsys tools using the *write_qor_data* command.

After a run through the full IC Compiler II or Fusion Compiler flow, use the *write_qor_data* command to capture the QoR data after significant flow stages, such as *compile_fusion*, *place_opt*, *clock_opt*, *routing*, and *route_opt*.

Use the *compare_qor_data* command at any time to provide a summary report of the progress of a single run or a comparison report of multiple runs. The runs do not have to be complete to use the *compare_qor_data* command. One label or stage must be captured for one run by using the *write_qor_data* command, so the *compare_qor_data* command can compile those results into the QoRsum web-based report.

You can view the QoRsum comparison report by using the *view_qor_data* command. This command initiates a localhost web server to serve the QoR data on disk to the web-based report. You can also view the report directly in a supported web browser. For

Feedback

example, open the index.html file in the output directory to view the report in Firefox. Some web browser versions have security restrictions that prevent the display of the QoRsum report data that uses the *file* protocol. The *view_qor_data* command provides a more predictable way to view the data through the *http* protocol with the localhost server. See the *view_qor_data* man page for more details.

Examples

The following example uses the *compare_qor_data* command to point to the results of a single run in the ./qor_data directory for viewing:

```
prompt> compare_qor_data -run_locations ./qor_data
```

The following example uses a different output directory and forces overwrite of any previous QoRsum report at that location:

```
prompt> compare_qor_data -run_locations ./qor_data \\
   -output ./qor_summary_report -force
```

The following example points to multiple FPM run results for comparison, and gives them meaningful names:

```
prompt> compare_qor_data -run_locations \\
   "/path/to/fpm_run1 /path/to/fpm_run2 /path/to/fpm_run3" \\
   -run_names "baseline_SP2 baseline_SP4 high_effort_timing_SP4"
```

compare_supplies

compares voltage levels or relative ON-ness between two given supplies.

Syntax

status *compare_supplies*

```
supply_list
[-on_status]
[-voltage_level]
```

Feedback

Data Types

supply_list	list
on_status	boolean
voltage_level	boolean

Arguments

supply_list

Specifies a list of 2 supplies. The first supply specified is treated as the 'reference' supply to which the second supply ('specified' supply) will be compared to. Supplies can either be supply net names or supply set handles.

-on_status

If specified, this option will return one of 4 values: "equal" if the reference supply is equal to the specified supply. "more_on" if the specified supply is more ON as compared to the reference supply. "less_on" if the specified supply is less ON as compared to the reference supply. "independent" if the specified supply may be more or less ON as compared to the reference supply depending on the PST State.

-voltage_level

If specified, this option will return one of 4 values: "equal", if both reference and specified supplies are at the same voltage and no level-shifting is needed. "higher", if reference supply is lower voltage as compared to the specified supply. "lower", if the reference supply is higher voltage as compared to the specified supply. "independent, if the reference supply is higher/lower voltage as compared to the specified supply depending on the PST State. If the two supplies specified belong to the same correlated supply group, they will be compared based on the rules for supplies in the same correlated supply group.

Description

This command is used to compare voltage levels or relative always-ON levels of two given supplies. Options -on_status and -voltage_level can be used separately or in combination. Supplies list must consist of exactly 2 supplies. If the specified supply has no states defined, we will treat it as equal to the reference supply and return equal for both on_status and voltage_level.

compile

Runs synthesis flow

Feedback

Syntax

status *compile*

```
[-no_boundary_optimization]
[-no_autoungroup]
[-checkpoint]
```

Arguments

`-no_boundary_optimization`

Disables optimization across hierarchical boundaries.

`-no_autoungroup`

Disables automatic ungrouping, preserving hierarchy.

`-checkpoint`

Writes 2 intermediate checkpoint databases.

Description

This command runs the synthesis flow. Note: This command is deprecated. It is replaced with *compile_fusion* command.

Examples

```
prompt> compile
```

See Also

- compile_fusion

---

compile_advanced_boundary_cells

Creates and places boundary cells around target objects in current design.

This command is deprecated and will be obsolete in future release. Please use *compile_targeted_boundary_cells command*.

Syntax

status *compile_advanced_boundary_cells*

```
[-target_objects {target_objects}]
[-include_touching_placement_blockages]
[-ignore_row_orientation]
[-add_placement_blockage]
[-voltage_area {objects}]
```

Feedback

Data Types

`target_objects` list

Arguments

`-target_objects {target_objects}`

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage and core area can be specified.

`-include_touching_placement_blockages`

Specifies that when boundary cells are created and placed, placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

`-ignore_row_orientation`

Specifies that when flipping between top and bottom.

`-add_placement_blockage`

Add placement blockage to meet boundary cells rules.

`-voltage_area {objects}`

Specifies the voltage areas to insert boundary cells.

Description

This command adds boundary cells around the boundaries of target objects, such as voltage areas, macros, blockages, and the core area, according to the boundary cell rules set by *set_boundary_cell_rules*.

Examples

The following example creates boundary cells around target placement blockages on both the left and the right edges of boundaries.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight
prompt> compile_advanced_boundary_cells -target_objects {PB_7 PB_8}
```

compile_boundary_cells

Creates and places boundary cells into a design. This command is used to replace the command *create_boundary_cells*.

This command is deprecated and will be obsolete in future release. Please use *compile_targeted_boundary_cells command*.

Syntax

status *compile_boundary_cells*

```
[-add_placement_blockage]
[-voltage_area {objects}]
```

Data Types

```
objects      list
```

Arguments

`-add_placement_blockage`

Add placement blockage to meet boundary cells rules.

`-voltage_area {objects}`

Specifies the voltage areas to insert boundary cells.

Description

This command adds boundary cells around the boundaries of objects, such as voltage areas, macros, blockages, and the core area, according to the boundary cell rules set by *set_boundary_cell_rules*.

Examples

The following example creates boundary cells on both the left and the right edges of boundaries.

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight
prompt> compile_boundary_cells
```

Feedback

---

compile_fusion

Runs synthesis, placement, and optimization on the current design.

Syntax

compile_fusion

```
[-list_only]
[-from startStage]
[-to endStage]
[-check_only]
```

Data Types

```
startStage   string
endStage     string
```

Arguments

`-list_only`

Prints the major stages that constitute the default flow for the *compile_fusion* command.

These stages are: *initial_map*, *logic_opto*, *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

This option cannot be used with the *-from* and *-to* options.

`-from startStage`

Specifies the starting stage for the *compile_fusion* command. Valid values are any of: *initial_map*, *logic_opto*, *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

The default behavior of *compile_fusion* without this option is to run from the first stage that is *initial_map*.

Feedback

`-to` *endStage*

Specifies the ending stage for the *compile_fusion* command. Valid values are any of: *initial_map*, *logic_opto*, *initial_place*, *initial_drc*, *initial_opto*, *final_place*, and *final_opto*.

The default behavior of *compile_fusion* without this option is to run to the last stage that is *final_opto*.

If both the *-to* and *-from* options are specified, then all stages from the *startStage* until the *endStage* are run in sequence. The *startStage* must be the same or earlier than the *endStage*, in the order shown for the *-list_only* option. If the same stage is given for both *startStage* and *endStage*, then only that specific stage is run.

`-check_only`

Checks for any discrepancy found in the library and design.

If the *-to* or *-from* option is specified, the library and design are checked to be sufficient only for those stages.

Description

This command runs during the initial part of the Fusion Compiler flow, running all of the major logical optimization, physical optimization, and placement operations from synthesis until clock tree synthesis. In a full Fusion Compiler flow, this command is followed by *clock_opt* for clock tree synthesis and post-clock optimization, placement, legalization, and global routing. This is followed by *hyper_route_opt* for full routing and post-route optimization.

The major steps of the *compile_fusion* flow are:

- initial_map: Design mapping and minimum area logic optimization
- logic_opto: Logic-based delay optimization
- initial_place: Initial coarse placement of the design
- initial_drc: Buffer tree building for high fanout nets and logical DRC fixing
- initial_opto: Physical optimization and incremental placement
- final_place: Incremental placement for timing and congestion improvement and placement legalization
- final_opto: Physical optimization for timing and power recovery and placement legalization

Feedback

Examples

The following example runs all seven stages of the *compile_fusion* flow. It starts from logic synthesis and ends up with an optimized design with legalized placement:

```
prompt> compile_fusion
```

The following example runs only the *initial_opto* stage. It performs physical optimization and incremental placement to optimize timing and congestion:

```
prompt> compile_fusion -from initial_opto -to initial_opto
```

The following example runs the last two stages of the *compile_fusion* flow, *final_place* and *final_opto*. It takes in a placed and optimized design as its input, incrementally improves the placement, and runs more physical optimization and placement legalization.

```
prompt> compile_fusion -from final_place
```

The following example runs the *compile_fusion* flow from synthesis through initial physical optimization.

```
prompt> compile_fusion -to initial_opto
```

See Also

- place_opt

---

compile_logical

Runs logical synthesis flow on the design.

Syntax

compile_logical

```
[-check_only]
[-from startStage]
[-to endStage]
```

Arguments

`-check_only`

Checks any discrepancy found in the library and design.

`-from startStage`

Specifies the starting stage for the *compile_logical* command. Valid values are any of: *initial_map*, *logic_opto*, and *initial_opto*.

The default behavior of *compile_logical* without this option is to run from the first stage that is *initial_map*.

Feedback

`-to` *endStage*

Specifies the ending stage for the *compile_fusion* command. Valid values are any of: *initial_map*, *logic_opto*, and *initial_opto*.

The default behavior of *compile_logical* without this option is to run to the last stage that is *initial_opto*.

If both the *-to* and *-from* options are specified, then all stages from the *startStage* until the *endStage* are run in sequence. The *startStage* must be the same or earlier than the *endStage*, in the order shown for the *-list_only* option. If the same stage is given for both *startStage* and *endStage*, then only that specific stage is run.

Description

By default, the command maps the generic cells to library cells and performs logic optimization.

The major steps of the *compile_fusion* flow are:

- initial_map: Design mapping and minimum area logic optimization
- logic_opto: Logic-based delay optimization
- initial_opto: Logical DRC fixing and incremental delay optimization

Examples

The following example runs logical compile flow.

```
prompt> compile_logical
```

The following example runs only the *logic_opto* stage.

```
prompt> compile_logical -from logic_opto -to logic_opto
```

The following example runs the post-compile DFT insertion flow It takes in a mapped and optimized design as its input, performs DFT insertion and ends up with an optimized design:

```
prompt> compile_logical -to logic_opto
prompt> insert_dft
prompt> compile_logical -from initial_opto -to initial_opto
```

Feedback

compile_pg

Creates a power and ground network including straps, rings, macro connections, standard cell connections and via connections based on the specified power ground strategies.

Syntax

status *compile_pg*

```
[-strategies strategy_list]
[-via_rule rule_list]
[-ignore_drc]
[-ignore_via_drc]
[-show_phantom]
[-undo]
[-tag tag_name]
[-create_ml_data]
[-use_ml_model]
```

Data Types

```
strategy_list   list
rule_list       list
tag_name        string
```

Arguments

`-strategies` *strategy_list*

Creates a power network based only on the specified list of strategies. By default, the tool creates a power ground network using all strategies which have been defined.

`-via_rule` *rule_list*

Specifies the via rule list between strategies and existing shapes. The via rule list *rule_list* contains strategy-level via rules defined by the *set_pg_strategy_via_rule* command. If no strategy via rule is specified, the default via defined in the technology file is created at all intersections between any two orthogonal shapes on different layers.

`-ignore_drc`

Creates the power network while ignoring DRCs for both wires and vias. By default, all DRCs are considered when creating the power network. This option is mutually exclusive with the *-ignore_via_drc* option.

`-ignore_via_drc`

Creates the power network while ignoring via DRCs. By default, all DRCs are considered when creating the power network. When this option is set, DRCs for wires are checked and fixed, DRCs within each stacked via are checked and

Feedback

fixed. Only DRCs between stacked vias and neighboring objects are ignored. This option is mutually exclusive with *-ignore_drc* option.

`-show_phantom`

Generates report for wires/vias that should be created but failed due to fixing DRC violation. Detailed information will be displayed in error browser. The report includes two parts, phantom wire and phantom via. Wire information and DRC violation are included in one phantom wire. Only DRC violations that cut part of wire shape while fixing will be included in phantom wire. Abutted phantom wires will be merged and reported together. Via information and DRC violation are included in one phantom via. Via information includes top/bottom wire information, via def, net name. DRC violation shows initial violation before fixing. If *-ignore_drc* or *-ignore_via_drc* is specified, phantom via will not be generated.

`-undo`

Removes the power and ground network created by the most recent *compile_pg* command.

`-tag` *`tag_name`*

Specifies a tag name to assign to all new vias and shapes created by this command. This tag name is used as contents of an user attribute tag for filtering collections at later stages (see the example in the EXAMPLES section). By default, no tags are assigned.

`-create_ml_data`

This option enables this command to create training data for training ML model for fixability prediction. When this option is set, the command only creates ML training data, not creating PG wires/vias.

`-use_ml_model`

This option enables this command to load pre-trained ML model for fixability prediction.

Description

This command creates the power network based on the specified power ground strategies.

Signal routes by default are ignored for DRC checking and correction during PG creation. Use the following app option to honor signal route DRC during PG creation.

```
prompt> set_app_options -list {plan.pgroute.honor_signal_route_drc true}
```

Feedback

Examples

The following example creates a power ground network using only the example1 and example2 strategies. The rule1 via rule is defined by the *set_pg_strategy_via_rule* command.

```
prompt> compile_pg -strategies {example1 example2}\\
                       -via_rule rule1
```

The following example compiles strategy example1 using 4 threads defined in the global host_options mt for via creation.

```
prompt> set_host_options -max_cores 4
prompt> compile_pg -strategies {example1}
```

The following example creates collections of vias and wires that are tagged with the name pg1.

```
prompt> compile_pg -tag pg1
prompt> set vias [get_vias -filter tag==pg1]
prompt> set wires [get_shapes -filter tag==pg1]
```

The following example creates ML training data in memory, output training data to files in the directory ./pg_model, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> compile_pg -create_ml_data
prompt> train_pg_ml_model
```

The following example creates ML training data in memory, output training data to files in directory pg_data_1, and train ML model based on the training data. The trained ML model is stored in the directory ./pg_model.

```
prompt> compile_pg -create_ml_data
prompt> create_pg_ml_data -output_directory pg_data_1
prompt> train_pg_ml_model -input_directory {pg_data_1}
```

The following example loads pre-trained ML model in the directory ./pg_model for fixability prediction to reduce runtime of PG via creation.

```
prompt> compile_pg -use_ml_model
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: *gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"*.

---

compile_tap_boundary_wall_cells

Creates and places tap, boundary, and wall cells in current design.

Syntax

status *compile_tap_boundary_wall_cells*

```
[-initial_insertion]
[-use_double_height_fill_wall]
[-hdr_n_tap_cells lib_cell_name]
[-ptap_optimization]
[-second_pass]
```

Data Types

```
lib_cell_name          string
```

Arguments

`-initial_insertion`

Specifies whether inserting only boundary cells and fill-wall cells.

`-use_double_height_fill_wall`

Replaces single-height fill-wall with double-height fill-wall.

`-hdr_n_tap_cells`

Specifies n-tap type HDR cells. This must be a 2X or 4X row-height cell.

Feedback

`-ptap_optimization`

Specifies whether to replace large PTap cell (2 tall-row height) with small PTap cell (2 short-row height).

`-second_pass`

Enable the process to remove redundant tap cells.

Description

This command adds tap, boundary, and wall cells in current block according to the tap, boundary, and wall cell rules set by the *set_tap_boundary_wall_cell_rules* command.

Examples

The following example creates tap, boundary, and wall cells in current block.

```
prompt> compile_targeted_boundary_cells
```

See Also

- check_legality
- remove_tap_boundary_wall_cell_rules

---

compile_targeted_boundary_cells

Creates and places boundary cells around target objects in current design.

Syntax

status *compile_targeted_boundary_cells*

```
[-target_objects target_objects]
[-include_touching_placement_blockages]
[-ignore_row_orientation]
[-target_boundary polygon]
[-all_targets]
[-insert_inside_target_boundary]
[-advanced]
```

Data Types

```
target_objects      list
polygon collection
```

Feedback

Arguments

`-target_objects {target_objects}`

Specifies the target objects to be around with boundary cells in current design. Objects including macro, voltage area, voltage area shape, placement blockage, route blockage, and core area can be specified. This is a required option if all_targets or target_boundary is not set. Note: Not all targeted objects in the floorplan can be supported and checked by the floorplan rules. User needs to check if targeted objects are legally placed and compliant with user's boundary cell rules.

`-include_touching_placement_blockages`

Specifies that when boundary cells are created and placed, placement blockages those touch specified target objects should be included. By default, no touching placement blockages are included.

`-ignore_row_orientation`

Specifies that when flipping between top and bottom.

`-target_boundary`

Specifies the region to create boundary cells around (outside). This is a required option if all_targets or target_objects is not set.

`-all_targets`

If specified, all voltage areas, placement blockages and macros are used as targets. This is a required option if target_objects or target_boundary is not set.

`-insert_inside_target_boundary`

Used with -target_boundary. Tool inserts boundary cells inside instead of outside the specified region.

`-advanced`

Enable AL-based variable-row engine for boundary cell insertion.

Description

This command adds boundary cells around the boundaries of target objects, such as voltage areas, macros, blockages, and the core area, according to the boundary cell rules set by *set_boundary_cell_rules*.

Examples

The following example creates boundary cells around target placement blockages on both the left and the right edges of boundaries.

Feedback

```
prompt> set_boundary_cell_rules -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight
prompt> compile_targeted_boundary_cells -target_objects {PB_7 PB_8}
```

See Also

- set_boundary_cell_rules

---

compute_area

Calculates the area of a geometric region.

Syntax

float *compute_area*

```
[-objects object_list]
[pos_object_list]
```

Data Types

```
object_list       collection
pos_object_list   collection
```

Arguments

`-objects object_list`

Specifies the objects to be used to define the geometric region to calculate the area of. Objects may be a heterogenous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

This is a required option if the *pos_object_list* option is not specified.

pos_object_list

Specifies the objects to be used to define the geometric region to calculate the area of. This positional option is provided for compatibility with other tools.

Description

This command calculates the area of the region specified by *objects*.

Feedback

---

compute_budget_constraints

Creates budget pin constraints based on estimate_timing (virtual in-place optimization).

Syntax

status *compute_budget_constraints*

```
[-setup_delay]
[-boundary]
[-latency_targets actual | estimated ]
[-busplans buses ]
[-modes mode_list ]
[-estimate_timing]
[-no_estimate_timing]
[-pins pin_list ]
[-input]
[-output]
[-unspecified]
[-feedthrough]
[-slack slack_value ]
[-fanin_cone]
[-fanout_cone]
[-balance true | false ]
[-ocv_percent percent ]
[-ocv_delay delay ]
[-host_options host_options_name]
[-default]
```

Data Types

```
buses         list
mode_list     list
pin_list      list
slack_value   float
percent       float
```

Feedback

```
delay         float
host_options_name  string
```

Arguments

`-setup_delay`

Calculates budget values for setup delay. See the description section for more details. You can specify this -setup_delay option in combination with the *-boundary* and/or *-latency_targets* options. If none are specified, setup and boundaries are computed, that is, the tool behaves the same way as if the user specified the -setup_delay and -boundary options.

`-boundary`

Calculates budget values for drives and loads at the block boundary. See the description section below for more details. You can specify this -boundary option in combination with the *-setup_delay* and/or *-latency_targets* options. If none are specified, setup and boundaries are computed, that is, the tool behaves the same way as if the user specified the -setup_delay and -boundary options.

`-latency_targets actual | estimated`

Calculates new clock latency targets to be used during budgeting. You can specify this -latency_targets option in combination with the *-setup_delay*, and/or *-boundary* options. If none are specified, setup and boundaries are computed, that is, the tool behaves the same way as if the user specified the -setup_delay and -boundary options. No other budget values are changed. During budget generation, you can use the clock latency targets to account for clock tree variation early in the design flow before clock tree synthesis. This option automatically sets the budget parameters for clock latency targets in your design. This is equivalent to manually using the *-early_latency*, *-late_latency* and *-crp* options with the *set_latency_budget_constraints* command. You must specify the *-latency_targets* option with the *-balance* option.

The argument to *-latency_targets* determines how the budget values are selected. The valid values are:

- *actual*: Budget values are selected to closely match the current clock latencies in your top-level design. The latencies can be either ideal or propagated, depending on whether your SDC file contains *set_propagated_clock* commands.
- *estimated*: Budget values are selected to closely match the predicted latency of your top-level clock tree. The prediction is based on the current placement of your clock tree elements (the clock trunk, Integrated Clock-Gating Cells (ICGs), clock pins). The current timing of the clock tree is not used. Estimated clock latencies are queried from the "clock trunk planning" tool; therefore, you need to make sure that you have run that first.

Feedback

`-busplans` *`buses`*

Automatically determines a fixed budget for segments along a budget path. This option is equivalent to manually setting the *-delay* option of the *set_segment_budget_constraints* command. Before passing the "buses" argument, you must first declare them by using the *create_budget_busplan* command. See the *create_budget_busplan* command man page for more details.

`-modes` *`mode_list`*

Specifies the list of modes to use to create the budget constraints. If this option is not specified, the command processes all modes with an active corner.

`-estimate_timing`

The estimate_timing option is obsoleted and scheduled to be removed in a subsequent release. Instead, use the plan.budget.estimate_timing_mode application option.

`-no_estimate_timing`

The no_estimate_timing option is obsoleted and scheduled to be removed in subsequent release. Instead, use the plan.budget.estimate_timing_mode application option.

`-pins` *`pin_list`*

Updates budget values for only the specified pins. You can further restrict the list of pins with the *-input* and *-output* options. By default, the command processes all pins of all budgeted blocks.

`-input`

Updates budget values for only input pins to blocks. You can further restrict the list of pins with the *-pins* option. By default, the command processes all pins of all budgeted blocks.

`-output`

Updates budget values for only output pins to blocks. You can further restrict the list of pins with the *-pins* option. By default, the command processes all pins of all budgeted blocks.

`-unspecified`

Updates budget values for only pins with no existing delay budget. By default, the command processes all pins of all budgeted blocks.

`-feedthrough`

Updates budget values only for paths with feedthroughs. A feedthrough path has a combinational connection that goes from the input of a block to the output of

Feedback

a block. By default, the command updates all paths, including those that start or end in the local block.

`-slack` *`slack_value`*

Updates budget values only for paths through pins where the budget slack is less than *slack_value*. Budget slack is defined as the amount by which the actual path delay is less than the budgeted path delay. If you specify *-slack 0.0*, only paths where the budget is tighter than the actual delay are rebudgeted.

`-fanin_cone`

Updates budget values only for pins that are in the timing fanin cone of the selected pins. This is useful when you want to rebudget many pins along the same path. By default, only selected pins are processed.

`-fanout_cone`

Updates budget values only for pins that are in the timing fanout cone of the selected pins. This is useful when you want to rebudget many pins along the same path. By default, only selected pins are processed.

`-balance true | false`

Sets latency targets as if there is zero skew between two blocks, even if the current timing analysis shows otherwise. You should set *-balance* to true whenever some of your clock timing is propagated (not ideal) or estimated, but you have not finished balancing your clocks across the whole chip.

During budgeting, it is possible that the clocks of your designs are not yet balanced. For example, you might have run clock tree synthesis in one of your blocks and not another. Or, you have run clock tree synthesis in each of your blocks, but have not yet balanced the blocks with each other. When you set *-balance* to true, the budgeter assumes that clocks are balanced.

If you want some clocks in your design to have a latency that is offset from other clocks, use the *-latency_offset* option of the *set_latency_budget_constraints* command to adjust the interclock balance.

You must specify the *-balance* option together with the *-latency_targets* option.

`-ocv_percent` *`percent`*

Adjusts the calculated early and late budget latencies so that they both vary by at least the specified *percent* value from the average.

When you use the *-latency_targets* option, it is possible that on-chip variation (OCV) is not considered. This happens if you are using ideal clocks and you did not supply separate early and late latencies. For example, if both the early and late latency in the design are 10, and you specify *-ocv_percent 5*, the early and late budget latency targets are set to 9.5 and 10.5, respectively.

Feedback

You must specify the *-ocv_percent* option with the *-latency_targets* option.

`-ocv_delay` *`delay`*

Adjusts the calculated early and late budget latencies so that they both vary by at least the specified *delay* value from the average.

When you use the *-latency_targets* option, it is possible that OCV is not considered. This happens if you are using ideal clocks (that is, not propagated clocks) and you did not supply separate early and late latencies. For example, if both the early and late latency in the design are 0, and you specify *-ocv_delay 0.2*, the budget latency targets are set to -0.2 and 0.2, respectively.

You must specify the *-ocv_percent* option with the *-latency_targets* option.

`-host_options` *`host_option_name`*

Specifies that the specified host option should be used for distributed processing. The host option is created with the *set_host_options* command. Note that only the part of *estimate_timing* that updates child blocks' views supports distributed processing; therefore, this option's effect depends on the design condition.

`-default`

Specifies that the default values of all the budgeting application options are used by the tool while computing the new budget constraints. When you use the *-default* option, for all the application options with names of the form *plan.budget.**, the user-specified values are ignored.

Description

This command automatically assigns new budget constraints for setup delay, boundary parasitics and drive, and/or clock latency. These parameters are controlled by using the *-setup_delay*, *-boundary*, and *-latency_targets* options. If you specify none of these options, setup and boundary are assumed. See the argument descriptions above for more information.

Note that constraints for hold delay do not depend on whether or not you run the *compute_budget_constraints* command. If you set the *plan.budget.write_hold_budgets* application option to true, hold constraints is automatically calculated and output by the *write_budgets* command.

You can use the *compute_budget_constraints* command to create setup delay constraints on your budget blocks. Running this command is equivalent to running *set_pin_budget_constraints* directly, except that the constraints are automatically generated. Constraints are generated to distribute slack of top-level paths to the various budget blocks. You can use the *report_budget* command to analyze the results.

Feedback

Path delays are automatically processed and constraints are set which are the same as those that can be manually set by the following options of the *set_pin_budget_constraints* command:

- -from_percent
- -from_delay
- -to_percent
- -to_delay
- -internal_percent
- -internal_delay

This affects *set_input_delay* and *set_output_delay* constraints in your final budget.

Block boundaries are automatically processed and constraints are set which are the same as those that can be manually set with the *-early_boundary* and *-late_boundary* options of the *set_pin_budget_constraints* command. This affects the *set_driving_cell*, *set_load* and *set_max_transition* constraints in your final budget.

By default, *compute_budget_constraints* processes all pins of all budget blocks. Blocks are assigned for budgeting by the *set_budget_options -add_blocks block_name* command. By default, all modes with an active corner are processed, unless you specify *-modes*.

When processing setup delays and boundary constraints, you can limit where *compute_budget_constraints* operates by using one or more of the *-pins*, *-input*, *-output*, *-feedthrough*, or *-slack* options. The *-fanin_cone* and *-fanout_cone* options allow *compute_budget_constraints* to also adjust budgets in the transitive fanin or output of specified pins.

Use the *set_budget_options* command to specify general options to be used when creating timing budgets. To manually set other specific budget parameters, use the *set_pin_budget_constraints*, *set_latency_budget_constraints*, and *set_boundary_budget_constraints* commands.

Use the *write_budgets* command to generate Synopsys Design Constraint (SDC) that can be applied to lower level blocks. The *report_budget* command generates information about the current budget calculation, allocation, and whether that budget is currently being met. Use the *write_script -include budget* command to save a Tcl script that includes your current settings from this command.

This command returns 1 on success, 0 otherwise.

Multiply Instantiated Blocks

Feedback

The *compute_budget_constraints* command automatically creates equal budgets for similar pins of multiply instantiated blocks (as directed by the *-same_as_mib* option of the *set_pin_budget_constraints* command). The budget represents the best compromise across the contexts of the multiple instances. However, if it appears that one or more instance pins has a constraint that is impossible to meet, those constraints might be different. You can report the pins with seemingly impossible constraints by using the *report_budget -warning_pins* command.

Examples

Automatically fill in the budget specification for any pin in any mode where no budget has yet been specified. But before you run the following command, ensure that you do not overwrite previously set boundary budgets.

```
prompt> compute_budget_constraints -unspecified -setup_delay
```

Automatically fill in the budget specification for any pin in any mode where no budget has yet been specified. Also make sure that boundary budgets are automatically created for all pins, regardless of whether or not they have delay budgets.

```
prompt> compute_budget_constraints -unspecified
prompt> compute_budget_constraints -boundary
```

Manually set internal delay budgets for all blocks, then use the *compute_budget_constraints* command to automatically fill in the unspecified feedthrough budgets. Also make sure that boundary budgets are created for all pins.

```
prompt> set_budget_options -add_blocks { core/CPU core/MMU exif }
prompt> set_pin_budget_constraints -all -internal_percent 20
prompt> compute_budget_constraints -unspecified -feedthrough
prompt> compute_budget_constraints -boundary
```

Automatically recalculate all existing budget constraints at the input of core/CPU in the current mode.

```
prompt> compute_budget_constraints -input -pins core/CPU/*
```

Find any pin in "mode2" where the budget is being met by less than 0.05 nanosecond. Assign a new budget to those pins and to pins in the fanin and fanout of those pins.

```
prompt> compute_budget_constraints -modes mode2 -slack 0.05 \\
   -fanin_cone -fanout_cone
```

Set up block clock latency targets for early in the flow. Use the current ideal clock specifications, but enforce OCV variability.

```
prompt> compute_budget_constraints -latency_targets actual \\
   -balance true -ocv_percent 5
```

Feedback

Set up block clock latency parameters for early in the flow. Use estimated latency and OCV. Use the *-balance true* option with the assumption that balancing will be done later in the flow.

```
prompt> compute_budget_constraints -latency_targets estimated \\
   -balance true
```

Set up block clock latency parameters to exactly match the circuit. The *-balance false* option assumes that the top-level clocks are already balanced.

```
prompt> compute_budget_constraints -latency_targets actual \\
   -balance false
```

See the *write_budgets* man page for more examples of the *-latency_targets* option.

compute_clock_latency

Updates the network latencies of real and virtual clocks after clock tree synthesis.

Syntax

status *compute_clock_latency*

Feedback

```
[-verbose]
```

Data Types

No data types

Arguments

`-verbose`

Displays additional columns in the update report to show reference clock, latency calculation method and the number of register clock pins used to calculate the latency.

Description

This command is used primarily to correct your block's timing constraints after clock tree synthesis. Clock tree synthesis inserts clock networks, which changes the latency on your clocks, and the apparent length of the datapaths at your block boundary. The *compute_clock_latency* command can adjust the clock latency on your I/O clocks so that the datapath length is maintained and your boundary constraints are still good. See the example below for more information.

The command calculates and updates the I/O latencies of real and virtual clock objects for all active mode and corner combinations. To calculate and update clock latencies, this command follows the directives set by *set_latency_adjustment_options* command for each mode. If no directives are given, then only the I/O latencies of real clock objects are updated. The latencies are calculated as the median of the clock network latencies at the clock sinks of the clock tree. For ideal clocks, a *set_clock_latency* command is run by the tool on the clock objects. For propagated clocks, I/O path latency is set internally on the clock objects. The I/O path latency is used in timing the input/output ports. The command updates latencies for all the active mode and corner combinations.

Note that *compute_clock_latency* is run automatically by the tool as part of integrated CTS and optimization flows. So it is important to use the *set_latency_adjustment_options* command, even if you don't intend to call *compute_clock_latency* explicitly.

Multicorner-Multimode Support

This command works on all active scenarios.

Examples

This example adjusts the latency on the specified I/O clocks. First, you must associate your I/O clocks with your internal clocks by using the *set_latency_adjustment_options* command. Then, when you run *compute_clock_latency*, the latency of the I/O clock will be set to match your internal clock. Notice that the *write_io_constraints* command can set latency adjustment options with *set_latency_adjustment_options* in the budget script.

Feedback

```
prompt> set_latency_adjustment_options \\
   -reference_clock my_internal_clock \\
   -clocks_to_update my_io_clock
prompt> synthesize_clock_trees
prompt> compute_clock_latency

- write_io_constraints

Feedback

compute_dff_connections

Traces connections in the current netlist. The results are used by the Data Flow Flylines tool in the GUI.

Syntax

```
status compute_dff_connections
[-max_reg register_count]
[-max_gate gate_count]
[-max_fanout fanout_count]
[-include_blocks list_of_designs]
[-retrace_blocks list_of_designs]
[-host_options host_option_name]
[-work_dir working_directory]
[-dont_include_abstracts]
```

Data Types

```
register_count      int
gate_count          int
fanout_count        int
list_of_designs     collection
host_option_name    string
working_directory   string
```

Arguments

`-max_reg register_count`

Specifies the maximum number of registers a path can contain and still be stored. Paths containing more than this number of registers are not stored for display. By default, this value is 3.

`-max_gate gate_count`

Specifies the maximum number of total gates a path can contain and still be stored. Gates are considered combinational cells that are not buffers or inverters. Paths containing more than this number of gates are not stored for display. By default, this value is 20.

`-max_fanout fanout_count`

Specifies the maximum fanout permitted for any net found while tracing the path. If a net with fanout greater than this limit is encountered, the path is not stored for display. By default, this value is 64.

`-include_blocks list_of_designs`

Specifies the abstract views for which to load previously saved trace data. The abstract view must be currently loaded or available in the library, and the *-max_reg*, *-max_gate*, and *-max_fanout* option values must be consistent

Feedback

with the previously saved data. If no compatible trace data file exists for the abstract view, you must also specify the *-retrace_blocks* option. By default, the commands loads all design views and abstract views for blocks returned by the *get_designs* command.

`-retrace_blocks` *`list_of_designs`*

Specifies a collection of abstract designs and physical blocks for which to retrace the netlist. *list_of_designs* is a set or subset of designs returned from the *get_designs* command. The specified designs are opened in design view and traced using the current tracer settings. The trace data is saved into a tracer data file that can be loaded by the Data Flow Flylines component in the GUI. Any design specified for this option must also be specified for the *-include_blocks* option. Note: after tracing any designs in this manner, the main design is reloaded and relinked, and all existing object collections become invalid and must be re-created.

`-host_options` *`host_option_name`*

Specifies the name of the host option to use for distributed processing. By default, this is empty and distributed processing is not used. See also *set_host_options*.

`-work_dir` *`working_directory`*

Specifies the directory in which to write the tracer files. By default, the command writes to a directory named "work_dir".

`-dont_include_abstracts`

Ignores abstracts and traces only in design views.

Description

This command invokes the Data Flow Flylines tracer. The tracer traces through the current netlist and stores paths that meet the specified constraints. These paths can then be displayed using the Data Flow Flylines GUI component. Several options are available to restrict the types of paths stored and limit the runtime required by the tracer (which might take several minutes for a larger design).

This command uses the settings specified by the *create_dff_trace_filters* command to stop tracing when any of the specified filter pins or filter nets are encountered during tracing.

If the current design contains abstract blocks, they can still be included in the tracer results. By specifying the *-include_blocks* and *-retrace_blocks* (if required) options, the specified abstract view designs can be opened in design view, either in the current session or a distributed session, depending on the current distributed processing settings. For more information, see the man pages for *set_host_options* and *run_block_script*.

Feedback

After saving tracer data files for the abstract designs, these sessions are closed and the saved tracer data files can be merged into the main tracer results. This only applies to abstract designs, and designs in design view are always automatically included in the main tracer results.

Examples

The following example traces the current design using these constraints: paths with a register depth of 2 or less, a maximum gate count of 25 or less, and a maximum fanout of 64, which is default. The Data Flow Flylines tool can be used to view the results in the GUI.

```
prompt> compute_dff_connections -max_reg 2 -max_gate 25
```

The following example traces the current design, but also forces a retrace of the ABS1 abstract block and includes the ABS1 and ABS2 abstract blocks in the main trace results.

```
prompt> set a1 [get_designs {ABS1 ABS2}]
{ABS1 ABS2}
prompt> set a2 [get_designs {ABS1}]
{ABS1}

compute_infeasible_path_overrides

checks infeasible path margins.

Syntax

status *compute_infeasible_path_overrides*

```
[-modes mode_list]
[-corners corner_list]
[-scenarios scenario_list]
[-group group_list]
[-apply_override_constraints]
[-output file_name]
[-nworst paths_per_endpoint_per_path_group]
```

Feedback

```
[-max_paths max_path_count_per_path_group]
[-verbose]
```

Data Types

```
mode_list              list
corner_list            list
scenario_list          list
group_list             list
file_name              string
```

Arguments

`-modes mode_list`

Specifies the scenarios to check infeasibility. If this option is given, all scenarios of the given modes are used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

`-corners corner_list`

Specifies the scenarios to check infeasibility. If this option is given, all scenarios of the given corners and the current mode is used. The *-scenarios* option must not be specified with this option. If both *-modes* and *-corners* are specified, all scenarios whose mode is specified by *-modes* and whose corner is specified by *-corners* are used.

`-scenarios scenario_list`

Specifies the scenarios to check infeasibility. The *-modes* or *-corners* option must not be given with this option.

`-group group_list`

Specify the list of path group names for checking infeasibility. Default is all path groups.

`-apply_override_constraints`

This option generates and applies path margins. Added path margins are all commented with SYNOPSYS_INFEASIBLE_PATH_OVERRIDE.

`-output file_name`

Specifies the name of the generated file containing timing exceptions to resolve infeasibility.

`-nworst paths_per_endpoint`

Specifies the number of paths to search per endpoint. Value is applied to each path group. The default value is 1000.

Feedback

`-max_paths` *`max_path_count`*

Specifies the number of paths to report. The default value is 10000. The max_paths value is applied to each path group.

`-verbose`

This option generate arrival time at startpoint and required time at endpoint along with infeasibility (arrival time at startpoint - required time at endpoint)

Description

This command checks timing paths infeasibility.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify a different scenario, use the *-scenarios* option or the *-corners* and *-modes* options.

Examples

this example checks infeasibility in scneario s1

```
prompt> compute_infeasible_path_overrides -scenario s1
```

This example checks infeasibility in current scenario and applies set_path_margin exceptions to resolve infeasibility.

```
prompt> compute_infeasible_path_overrides -apply_override_constraints
```

See Also

- remove_path_margin

---

compute_polygons

Performs a boolean geometric operation and returns the result as a geo_mask.

Syntax

collection *compute_polygons*

```
-operation AND | OR | XOR | NOT
-objects1 object_list
-objects2 object_list
```

Data Types

```
object_list       collection
```

Feedback

Arguments

`-operation AND | OR | XOR | NOT`

Specifies the Boolean operation to perform:

```
AND       Get the region covered by both objects1 and objects2
OR        Get the region covered by either objects1 or objects2
XOR       Get the region covered by objects1 or by objects2 but
                  not both
NOT       Get the region covered by objects1 but not by objects2
TOUCHING  Get the region covered by the poly_rects in objects1
 that abuts
                  or overlaps with one or more poly_rects
 in objects2
INTERSECT Get the region covered by the poly_rects in objects1
 that overlaps
                  with one or more poly_rects in objects2
```

This is a required option.

`-objects1 object_list`

Specifies the objects to be used to define the geometric region of the first argument of the operation. Objects can be a heterogeneous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

If voltage_areas, voltage_area_shapes, or site_arrays are included in *object_list*, please note their effective shapes are used for their area contribution. This implies you may get different results than you expect due to the stacking orders of the shapes involved. To isolate individual shapes' area contributions independent of their stacking order, you can convert them to poly_rects first (using the *create_poly_rect* command), then use the resulting poly_rects in *object_list*.

This is a required option.

`-objects2 object_list`

Specifies the objects to be used to define the geometric region of the second argument of the operation, and has the same form and functionality as the *-objects1* argument.

This is a required option.

Feedback

Description

This command performs the specified Boolean operation on *objects1* and *objects2*, and returns a collection that contains the result as a geo_mask object.

Examples

The following example returns a geo_mask with a region that is the union of two shapes.

```
prompt> compute_polygons -objects1 [get_shapes RECT_0] -operation AND \\
        -objects2 [get_shapes RECT_1]
```

The following example returns a geo_mask with the region composed of the shapes on a layer, except for the areas of shapes that lie within a rectangle.

```
prompt> compute_polygons -objects1 [get_layers M1] -operation NOT \\
        -objects2 [create_poly_rect -boundary {{0 0} {200 100}}]
```

See Also

- compute_area
- copy_to_layer
- create_geo_mask
- create_poly_rect
- split_polygons
- resize_polygons
- transform_polygons

---

connect_freeze_silicon_tie_cells

Connect target pins to tie cells in freeze silicon mode.

Syntax

status *connect_freeze_silicon_tie_cells*

```
[-cells cells]
[-max_fanout number]
[-max_wire_length distance]
[-tie_high_lib_cell lib_cell]
[-tie_low_lib_cell lib_cell]
```

Data Types

```
cells       collection
lib_cell    collection
```

Feedback

number integer
distance distance

Arguments

`-cells` *cells*

Specifies the target cells to be connected to tie cells. These cells must have pins already connected to tie-low nets or tie-high nets. This option is optional, and if this option is not specified, target cells include all cells which have pins already connected to tie nets in the design.

`-max_fanout` *number*

Specifies the maximum number of pins that can be driven by a single tie-high or tie-low cell. If you do not specify this option, the maximum fanout is 8.

`-max_wire_length` *distance*

Specifies the maximum Manhattan wire length in microns from a tie-high or tie-low cell to each driven cell pin. If you do not specify this option, the maximum wire length is 100.

`-tie_high_lib_cell` *lib_cell*

Specifies the reference cell type of tie cells to be used for tie high connections. If not specified, all types of tie high cell can be used for tie high connections If you use this option, you must also use the *-tie_low_lib_cell* option.

`-tie_low_lib_cell` *lib_cell*

Specifies the reference cell type of tie cells to be used for tie low connections. If not specified, all types of tie low cell can be used for tie low connections If you use this option, you must also use the *-tie_high_lib_cell* option.

Description

This command connect pins that are already connected to tie nets to tie cells in freeze silicon mode. If users specify the option *-cells* , only pins of these cells that are connected to tie nets will be connected to tie cells. And these pins are connected to surrounding tie cells as close as possible.

This command can work in freeze silicon mode, and spare tie cells can be used to create new tie cells in freeze silicon mode if needed.

The pins that already connected to tie nets are only connected to tie cells in the same voltage area of these pins by this command.

This command support spare tie cells and non-spare tie cells. Non-spare tie cells can only be connected to pins in the same hierarchy. But for a spare tie cell, it could be moved to another hierarchy (swap out and a new tie cell is created) and connected to pins in that hierarchy.

Feedback

Cells must be placed before the command, include tie cells and cells that need to be connected to tie cells. And cells inside sub block are also not supported.

Users can specify maximum fanout (the maximum number of pins that can be driven by a single tie cell) and maximum wire length (the maximum Manhattan wire length between a pin and its tie cell driver) constraints.

Users can specify tie high and tie low lib cells, and then only tie cells of the specified lib cells can be used for tie connections. If not specified, all tie-high and tie-low cells can be used for tie connections.

When this command succeeds, the toll will report a summary like this:

```
****************************************
Report : ECO connect_freeze_silicon_tie_cells Summary
 ...

****************************************
Total 168 pins are connected to tie cells.

Voltage Area DEFAULT_VA:
    Connect    6 pins to tie-low cells.
    Connect    4 pins to tie-high cells.

Voltage Area pd2:
    Connect  102 pins to tie-low cells.
    Connect   34 pins to tie-high cells.

Voltage Area pd3:
    Connect    6 pins to tie-low cells.
    Connect    2 pins to tie-high cells.

Voltage Area pd4:
    Connect    8 pins to tie-low cells.
    Connect    6 pins to tie-high cells.
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

In the following example, there is no option specified, and all pins that already connected to tie nets will be connected to tie cells.

```
prompt> connect_freeze_silicon_tie_cells

****************************************
Report : ECO connect_freeze_silicon_tie_cells Summary
 ...

****************************************
```

Feedback

```
Total 22 pins are connected to tie cells.

Voltage Area pd3:
    Connect    6 pins to tie-low cells.
    Connect    2 pins to tie-high cells.

Voltage Area pd4:
    Connect    8 pins to tie-low cells.
    Connect    6 pins to tie-high cells.
1
```

In the following example, only pins of the specified cells are connected to tie cells if they are already connected to tie nets.

```
prompt> connect_freeze_silicon_tie_cells -cells {alu/EcoCell*}
```

In the following example, the options *-max_fanout* and *-max_wire_length* are specified, and the command will follow these constrains when connect pins to tie cells.

```
prompt> connect_freeze_silicon_tie_cells -max_fanout 5 -max_wire_length
 20
```

In the following example, the options *-tie_high_lib_cell* and *-tie_low_lib_cell* are specified, and the command will only use tie cells of the specified lib cells for tie connections.

```
prompt> connect_freeze_silicon_tie_cells -tie_high_lib_cell
 tcbn90ghvt/TIEHHVT \\
    -tie_low_lib_cell tcbn90ghvt/TIELHVT
```

---

connect_logic_net

Connects a logic net to logic ports.

Syntax

status *connect_logic_net*

```
net_name
[-ports port_list]
[-reconnect]
```

Data Types

```
net_name   string
port_list  list
```

Feedback

Arguments

net_name

Specifies the net name.

-ports *port_list*

Specifies the logic ports connected to the net. The ports must be on the interface of the active scope or on the design elements that are located in the active scope and its descendants.

-reconnect

Allows a port that is already connected to a net to be disconnected from the existing net and connected to the newly specified net.

Description

The connect_logic_net command connects a logic (non-PG) net to the specified logic ports. The net is propagated through implicitly created ports and nets throughout the logic hierarchy in the descendant subtree of the active UPF scope as required to support connections created by connect_logic_net. A unique global driver needs to be present among the logic net and logic ports if there exists a logic port not in the same hierarchy as any segment of the given net in the active UPF scope. This command will not support multiple driver nets. That is, it will not implement connection if there are multiple drivers specified, or the net has multiple drivers.

On the path from a specified logic port to the logic net:

-

no internal port can be created on a power domain boundary when establishing a new connection;

-

there cannot be a different net already connected to the logic port.

The *-reconnect* option disconnects any existing net from the specified port and connects the newly specified net to all the ports present in the port_list.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

See Also

- connect_net
- create_logic_port
- create_logic_net

Feedback

connect_net

Connects a net or scalar nets of net_bus to port, pins and scalar ports of port_bus.

Syntax

int *connect_net*

```
[-design design]
-net net
-port_name port_name
net
terms
```

Data Types

```
design     string
net        list
port_name  string
terms      list
```

Arguments

`-design design`

Specifies the design in which to connect the nets. If no design is specified, the nets are connected in the current design.

`-net net`

Specifies the net or net_bus to connect. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified, then terms must contain the same width port_bus or length of the scalar port array list should be same as bus width of the net_bus.

net

Specifies the net or net_bus to connect. It can be a name or collection. The net can be a scalar (single-bit) net or net_bus and must exist in the current design. If net_bus is specified, then terms must contain the same width port_bus or length of the scalar port array list should be same as bus width of the net_bus. This positional argument is provided for compatibility with other tools.

`-port_name port_name`

Specifies the base name to use as the name of new ports that are created on subdesigns to make the connection.

terms

Specifies a list of ports, port_bus and pins to which the net is to be connected. The ports and pins must exist in the current design. If a specified port, scalar

Feedback

port of port_bus or pin is already connected, the command issues an error message.

Description

This command connects a net or scalar net of the net_bus to the specified ports, port_bus and pins, possibly across several levels of hierarchy. port_bus connections across hierarchies is not supported. A net can be connected to many ports and pins, however you cannot connect a port or pin to more than one net. Ports and nets are created as needed to cross hierarchy.

If a port or pin cannot be connected, the port or pin is skipped. The remaining ports and pins in the *terms* are connected.

The number of connected ports and pins are returned.

To disconnect objects on a net, use the *disconnect_net* command. To display ports and pins on a net, use the *all_connected* command.

Examples

The following example connects a net named *NET0*. The *all_connected* command returns the objects connected to *NET0*.

```
prompt> connect_net -net NET0 [get_ports { A1 A2 } ]
prompt> connect_net -net NET0 [get_pins U1/A]
prompt> all_connected NET0
{"A1", "A2", "U1/A"}
```

The following example connects a net_bus named *N[7:0]* to port_bus named *P[7:0]* so that N[7] is connected to P[7], N[6] is connected to P[6] ..,N[0] to P[0].

```
prompt> connect_net -net N P
8
# The nets can be explicitly mentioned as follows
prompt> connect_net -net [get_net_buses N] [get_port_buses P]
8
prompt> all_connected N[1]
{"P[1]"}
```

- disconnect_net

---

connect_pg_net

Connects power, ground, and tie-off pins to the power and ground nets. The command supports both an automatic mode and a manual mode. The default is automatic mode.

Feedback

In automatic mode, the tool derives the power and ground nets from the power intent of the design. Automatic mode requires committed UPF descriptions and logic libraries with power and ground pins. In manual mode, you specify the power and ground nets.

Syntax

status *connect_pg_net*

```
[-automatic]
[-pg]
[-tie]
[-all_blocks]
[-block block_list]
[-design design]
[-net net]
[port_pin_list]
[-create_nets_only]
[-reconnect true|false]
[-report_connection_summary true|false]
[-verbose]
```

Data Types

block_list	list
design	collection
net	list
port_pin_list	list

Arguments

`-automatic`

Specifies automatic mode. This option cannot be used with *-net* or *port_pin_list* options.

`-pg`

Specifies that only leaf power and ground pins are connected. If *-pg* and *-tie* options are not specified, both PG and tie-off pins are connected in automatic mode. This option cannot be used with *-create_nets_only*, *-net* or *port_pin_list* options.

`-tie`

Specifies that only tie-off pins are connected. If *-pg* and *-tie* are not specified, both PG and tie-off pins are connected in automatic mode. This option cannot be used with *-create_nets_only*, *-net* or *port_pin_list* options.

`-all_blocks`

Traverses all physical blocks during auto PG connection. This option cannot be used with *-block*, *-net* or *port_pin_list* options.

Feedback

`-block` *`block_list`*

Traverses the current design, as well as the physical blocks specified in *block_list* during auto PG connection. Blocks in *block_list* that are not in current design are ignored. This option cannot be used with *-all_blocks*, *-net* or *port_pin_list* options.

`-design` *`design`*

Specifies the design in which to connect power and ground nets. If no design is specified, the power and ground nets are connected in the current design.

`-net` *`net`*

Specifies the PG net to connect. The *net* argument can be a name or collection. The net must be a scalar (single-bit) PG net and must exist in the current design.

`port_pin_list`

Specifies a list of ports and pins to which the net is to be connected. The ports and pins must exist in the current design.

By default, if a specified port or pin is already connected, the command disconnects the existing connection and makes a new connection. The behavior of reconnection can be specified by *-reconnect* command option.

`-create_nets_only`

Creates topmost PG nets automatically based on power constraints, even when the design contains unmapped cells.

`-reconnect true|false`

Specifies whether to allow reconnection in manual mode when a specified port/pin already has an existing net connection. By default, reconnection is allowed.

`-report_connection_summary true|false`

Specifies whether to report summary of PG connection changes. By default, pg connection summary is reported.

`-verbose`

Prints the details of the changes to the power, ground, and tie-off connections.

Description

The *connect_pg_net* command creates the power and ground network for your design by connecting the power, ground, and tie-off pins to the power and ground nets in your design.

The command supports two modes: automatic mode and manual mode.

Feedback

In automatic mode, the tool derives the power and ground nets from the power intent of the design. UPF must be committed before running *connect_pg_net* in automatic mode. In addition, automatic mode requires logic libraries with power and ground pins. In automatic mode, the tool creates the power and ground nets if they do not already exist. The tool reports PG net and PG pin connections status at the end.

For non UPF designs, automatic mode derives power and ground nets based on the primary supply nets of default power domain. The system default values of the application options (mv.pg.default_power_supply_net_name, mv.pg.default_power_supply_port_name, mv.pg.default_ground_supply_net_name and mv.pg.default_ground_supply_port_name) are used to specify the primary supply names of the default power domain if no PG nets from Verilog or DEF exist in the non UPF design. If the application options are not explicitly set and one power net and one ground net is specified as PG nets in Verilog or DEF, automatic mode automatically chooses them as primary supply names of the design. If there is more than one power or ground nets, the application option has to be explicitly set to specify the primary supply names, even if it is the same as the application option's system default.

In manual mode, use *-net* option to specify the power and ground nets. Using *-net* option invokes the tool in manual mode. You can use manual mode for single-voltage or multivoltage designs.

Examples

The following example uses the *connect_pg_net* command in automatic mode to connect all unconnected power and ground pins based on the power domain connections.

```
prompt> connect_pg_net -automatic

****************************************
Report : Power/Ground Connection Summary

---

connect_pg_via_ladders

Connect via ladders to closest PG straps.

Syntax

status *connect_pg_via_ladders*

```
[-nets pg_nets]
[-cells instances]
[-pins pins]
[-target_layer string]
[-target_shapes shapes]
[-ignore_drc]
[-tag string]
[-via_masters via_masters]
[-shape_use shape_use]
[-number_of_targets integer]
[-max_extension distance]
```

Data Types

```
pg_nets           string or list of string
instances         collection
shape_use         string
pins              collection
shapes            collection
via_masters       string or list of string
distance          float
```

Feedback

Arguments

`-nets` *`pg_nets`*

Specifies the power ground nets to be connected. -nets must be used together with -cells. -nets is exclusive with -pins.

`-cells` *`instances`*

Specifies the instances to be connected. Tool only makes connection of instances having via ladders created for corresponding pins. -cells must be used together with -nets. -cells is exclusive with -pins.

`-pins` *`pins`*

Specified the pins to be connected. Tool only makes connection of pins with which via ladders associated. -pins is exclusive with -cells and -pins.

`-target_layer string`

Specifies the target layer on which power straps should be connected.

`-target_shapes` *`shapes`*

Specifies a collection of shapes which the via ladders should be connected to.

`-ignore_drc`

Specifies if drc should be checked for the connection.

`-tag string`

Specifies the tag info for created PG shapes/vias.

`-shape_use` *`shape_use`*

Specified the shape use of created PG shapes/vias. By default it is stripe

`-via_masters` *`via_masters`*

Specifies the via masters to be used for via ladder connection. If not specified, default contact code will be used.

`-number_of_targets integer`

Specifies the number of straps to which the via ladder should connect. If not specified, only one connection will be made for each via ladder.

`-max_extension distance`

Specifies the maximum extension of the via ladder to make connection. If not specified, the range is not limited. If max extension is specified, the command will try all the targets within the range, in the order of distance, until the number of connections specified by -number_of_targets is met. If max extension is not specified, the command only tries the number of targets specified by -number_of_targets, no matter if a connection can be made successfully or not.

Feedback

Description

This command tries to connect top level shape of via ladders to existing PG mesh. It will only use straight connections. As a result, there might be via ladders left open.

Examples

The following example make via ladders of secondary pg pins vdd_ron to PG straps on M5.

```
prompt> connect_pg_via_ladders -nets vdd_ron -cells $cell_collection
 -target_layer M5
```

See Also

- compile_pg
- route_group

---

connect_pins

Connects a set of pins together across hierarchy.

Syntax

```
int connect_pins
[-design design]
-incremental
-non_incremental
-driver pin
-port_name port_name
loads
```

Data TYpes

```
design       collection
pin          collection
port_name    string
loads        list
```

Arguments

`-design design`

Specifies the design in which to find the objects. If no design is specified, the nets are connected in the current design.

`-incremental`

Make the operation incremental. The driver pin must be connected to a net otherwise the option does not have any effect. Any existing loads on the net connected to the driver pin are preserved. Please note that connect_pins

Feedback

behavior defaults to -incremental usage, therefore explicit use of -incremental is not required.

`-driver` *pin*

Specifies the driving pin of the network. It can be a name or collection. The pin must exist in the current design.

`-port_name` *port_name*

Specifies the base name to use as the name of new ports that are created on subdesigns to make the connection.

loads

Specifies a list of ports and pins to which the driving pin is to be connected. The ports and pins must exist in the current design.

`-non_incremental`

Make the operation non-incremental. If a specified load port or pin is already connected to something else, it will be disconnected and then connected to the driving pin.

Description

This command connects a set of pins together, possibly across several levels of hierarchy. Ports and nets are created as needed to cross hierarchy. Existing nets and ports may be reused to complete a connection.

The number of connected load ports and pins are returned.

To disconnect objects on a net, use the *disconnect_net* command. To display ports and pins on a net, use the *all_connected* command.

Examples

The following example connects a the driving pin u20/ZN to a number of input pins across several levels of hierarchy. The *getPins* command then returns the list of pins connected across the hierarchy.

```
prompt> connect_pins -driver u20/ZN {u21/I u1/u22/I u2/u23/I u4/u2/u24/I
 u2/u2/u2/u25/I}}
5
prompt> get_pins -leaf -of_objects [get_nets -of [get_pins u20/ZN]]
u1/u22/I u2/u2/u2/u25/I u2/u23/I u20/ZN u21/I u4/u2/u24/I
```

- get_pins

connect_power_switch

Connects the pins of the coarse-grain power switch cells in the design.

Syntax

int *connect_power_switch*

```
-source object
-port_name port_name
-mode hfn | daisy | fishbone | clustering | shortest | vertical |
 horizontal
[-ack_out object]
[-ack_port_name port_name]
[-direction <horizontal | vertical>*]
[-start_point <lower_left | upper_left | lower_right | upper_right | top
 | bottom | left | right>*]
[-ring_direction clockwise | counter_clockwise]
[-lib_pin library_pin_names]
[-voltage_area voltage_areas]
[-object_list objects]
[-keep_order]
[-width width]
[-fine_grained_lib_pins library_pin_pairs]
[-connect_sleep_and_ack_in_shared_domains]
[-max_distance_to_va_boundary distance]
```

Data Types

```
object              string
port_name           string
library_pin_names   list
voltage_areas       list
objects             collection
width               float
library_pin_pairs   list
distance            positive integer
```

Arguments

`-source object`

Specifies the pin or port from which to connect. The direction of the pin or port cannot be inout. In clustering mode, this option supports a collection of pins and ports.

Feedback

`-port_name` *`port_name`*

Specifies the base name to use as names of switch ports when a new port is created on the subdesigns to make the connection. It is a required option.

`-mode hfn | daisy | fishbone | clustering | shortest | vertical | horizontal`

Specifies whether the switch connections of coarse-grain switch cells are to be made in high fanout, daisy, fishbone, clustering, shortest, vertical, or horizontal style. It is a required option.

`-ack_out` *`object`*

Specifies the pin or port or net that is to be used as acknowledge-out connection. It is optional and is only allowed with *-mode daisy* or *-mode fishbone*. For situations where a pin and net have the same name, pin takes precedence over net.

`-ack_port_name` *`port_name`*

Specifies the base name to use as names of acknowledge ports when a new port is created. This is required with the *-ack_out* option in *-mode daisy* or *-mode fishbone*.

`-direction <horizontal | vertical>*`

Specifies the direction for the daisy and fishbone connections. Requires *-mode daisy* or *-mode fishbone*. It is used only when the tool tries to infer the daisy chain direction based on the instantiated coarse-grain switch cell locations. This option can also be used to specify the direction of connections for branches connected to the main trunk in *-mode fishbone*.

If *-mode daisy* and multiple *-object_list* are specified, *-direction* can take a list of values, one for each object list, to specify the connection direction for coarse-grain power switch cells in each object list. If there are more *-object_list* than the number of values listed in *-direction*, the last value in *-direction* will be used as the connection direction for the rest of the object lists.

`-start_point lower_left | upper_left | lower_right | upper_right | top | bottom | left | right`

Specifies the starting point for connections. Requires *-mode daisy*, *-mode fishbone*, *-mode vertical* or *-mode horizontal*. This is not a required option.

In daisy or fishbone mode, this option can only be used with *-direction* and allowable values are 'lower_left', 'upper_left', 'lower_right' and 'upper_right'. It is used to infer the startpoint for daisy or fishbone connections, and this is helpful in connecting the source pin to the nearest starting coarse-grain switch cell. For fishbone connections, this option determines the starting point for the trunk of fishbone connections.

Feedback

If *-mode daisy* and multiple *-object_list* are specified, *-start_point* can take a list of values, one for each object list, to specify the starting position for coarse-grain power switch cells in each object list. If there are more *-object_list* than the number of values listed in *-start_point*, the last value in *-start_point* will be used as the starting point for the rest of the object lists.

In vertical or horizontal mode, power switch cells are connected vertically or horizontally in column-by-column basis. This option specifies the side of core area that the connection of each column should start from. In vertical mode, the allowable values are ‘top’ and ‘bottom’. In horizontal mode, the allowable values are ‘left’ and ‘right’. When it is not specified, by default, the connection of each column starts from the side of core area that is closest to the source pin.

`-ring_direction clockwise | counter_clockwise`

Specifies the direction for Ring style switch placement. Now this option can support coarse-grain switch cells inserted using *create_power_switch_ring* or by other non-SNPS tool. When this option is specified with *-direction*, the *-direction* will be ignored. And this option supports *daisy* mode only.

`-lib_pin` *`library_pin_names`*

Specifies the list of library input and output pins that should be used in all the connections modes. This is a required option for coarse-grain switch cells that have multiple switch and acknowledge pins. The command issues an error message if a coarse-grain switch cell with multiple input or output is used but does not have its library pins specified in this option. This option requires that the specified library pins are valid switch or acknowledge library pins of coarse-grain power switch cells.

`-voltage_area` *`voltage_areas`*

Specifies the voltage areas. The command tries to collect the coarse-grain switch cells in the specified voltage area and connect them. This command supports both single shape and disjoint voltage areas.

`-object_list` *`objects`*

Specifies the list of coarse-grain switch cells on which to perform the connections. If *-mode daisy* or *-mode fishbone* is specified, the tool will automatically sort the object list to do the connections.

If *-mode daisy* is specified, multiple *-object_list* are allowed. In this setting, the relative order of coarse-grain power switch cells in different *-object_list* will be maintained while power switch cells in the same *-object_list* will be sorted. For example, if sw1 is in the first *-object_list* and sw2 is in the second *-object_list*, sw1 will always appear before sw2 in the final power switch chain.

Feedback

`-keep_order`

Specifies whether to keep the order of coarse-grain power switch cells you specify with -object_list option. It only works for *-mode daisy*. You cannot specify -keep_order for *-mode hfn* or *-mode fishbone*. Without -keep_order option, tool will sort power switch cells automatically.

`-width` *`width`*

Specifies the width of columns in vertical or horizontal mode. When it is not specified, the column width by default is the largest cell width of power switch cells that are being connected by the command.

`-fine_grained_lib_pins` *`library_pin_pairs`*

Specifies the list of sleep and ack library pin pairs of fine-grained macro cells with existing connections. This option can only be used with *-connect_sleep_and_ack_in_shared_domains*.

`-connect_sleep_and_ack_in_shared_domains`

When this command option is specified, the tool will connect the sleep input and ack output of other shared power domains if they are unconnected. The ack output specified in the '-ack_port' command option will be connected to and drive the control inputs and ack outputs of other shared power domains in daisy-chain fashion.

`-max_distance_to_va_boundary` *`distance`*

Specifies the maximum distance from voltage area boundary for coarse-grain power switch cells to be considered to be at voltage area boundary. This option is valid for *-mode shortest* only. If this option is not specified, the distance to boundary of voltage area are not considered.

Description

The *connect_power_switch* command connects control and ack_out pins of coarse-grain power switch cells that are instantiated and placed in the design. Connection modes and ordering for the coarse-grain switch cells are specified by options. The command can identify the coarse-grain switch cells in the design based on Liberty syntax and can connect them in either high-fanout, daisy-chain, fishbone, clustering, shortest, vertical, or horizontal style.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

- create_power_switch_ring

---

connect_supply_net

Connects the supply net to the specified supply ports and pins.

Syntax

status *connect_supply_net*

```
supply_net_name
-ports list
-vct vct_name
```

Data Types

```
supply_net_name       string
list                  list
vct_name              string
```

Arguments

supply_net_name

Specifies the name of the supply net to connect. If a supply net with the specified name does not exist in the current scope, the supply net cannot be connected. This is a required option and must be specified.

Feedback

`-ports` *list*

Specifies which supply ports and pins to connect to the supply net. The name is a hierarchical name.

`-vct` *vct_name*

Specifies the value conversion table (VCT) to be used in this connection. A value conversion table (VCT) defining how values are mapped from UPF to an HDL model or from the HDL model to UPF.

The tool supports the following 14 predefined VCT names: UPF2VHDL_SL, UPF_GNDZERO2VHDL_SL, UPF2SV_LOGIC, UPF_GNDZERO2SV_LOGIC, VHDL_TIED_HI, SV_TIED_HI, VHDL_TIED_LO, SV_TIED_LO, VHDL_SL2UPF, VHDL_SL2UPF_GNDZERO, SV_LOGIC2UPF, SV_LOGIC2UPF_GNDZERO, SV_LOGIC2UPF_MD, and SV_LOGIC2UPF_GNDZERO_MD.

The tool also support user defined vcts created by *create_hdl2upf_vct* and *create_upf2hdl_vct*.

Description

The *connect_supply_net* command connects a supply net to any supply port or pin. The command overrides (has higher precedence than) any auto-connection semantics that might otherwise apply. If a design element is not connected explicitly to any supply net using the *connect_supply_net* command, it will share the primary power or ground supply net with the power domain that it belongs to.

The supply net must be created in the same power domain as the supply port, before they can be connected. The instance that contains the pin must also be in the extent of the same power_domain. If the specified supply net or port or pin is not in the extent of same power domain, this command fails.

This command returns 1 on success, returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example connects a supply net VSS with supply port VSS:

```
prompt> create_power_domain PD1 -elements INST_1
PD1
prompt> create_supply_net VSS -domain PD1
VSS
prompt> create_supply_port VSS -domain PD1
VSS
prompt> connect_supply_net VSS -ports VSS
1
```

Feedback

- create_hdl2upf_vct

---

connect_topology_nodes

Daisy chain connect selected or specified topology nodes in the current design.

Syntax

collection *connect_topology_nodes*

```
[-direction down | left | right | down]
[object_list]
```

Data Types

```
object_list   collection or selection
```

Arguments

```
-direction down | left | right | down
```

Specifies the direction of daisy chain connection.

The direction values are:

```
down connects nodes from top to bottom
left connects nodes from right to left
right connects nodes from left to right
up connects nodes from bottom to top
```

Description

The *connect_topology_nodes* command creates the topology edges to connect selected or specified topology nodes in given direction.

Note, if some nodes were already connected they will be omitted from operation.

Examples

The following example connects selected topology nodes in direction from left to right.

Feedback

```
prompt> connect_topology_nodes -direction right
```

The alternative syntax uses collection to specify objects.

```
prompt> connect_topology_connect [get_selection] -direction right
```

---

convert_aocv_pocv

Converts AOCV derating factor tables to POCV coefficient tables.

Syntax

status *convert_aocv_pocv*

```
[-depth depth_row]
[-corners corner_list]
```

Data Types

```
depth_row        integer
corner_list      list
```

Arguments

`-depth` *depth_row*

Specifies to use the *depth_row* entry in the AOCV table to do the conversion. By default, the first entry of the depth row in the AOCV table is used.

`-corners` *corner_list*

Indicates the list of corners for which the AOCV derate factors are to be converted and the converted POCV coefficients are to be applied. If this option is not provided, the corner associated with the current scenario is used.

Description

This command converts AOCV tables annotated on design objects (previously loaded by *read_ocvm* command) to POCV tables and applies the converted POCV tables onto the same design object.

The AOCV to POCV conversion is based on the following equation.

Feedback

```
POCV_coefficient_late = (AOCV_derate - 1) / 3
POCV_coefficient_early = (1 - AOCV_derate) / 3
```

In the above equation, AOCV_derate refers to the *depth_row* entry in the AOCV table. If the AOCV table has distance information, the worst-case distance is used.

One advantage of using this command is reducing the pessimism in AOCV GBA analysis.

To report the converted POCV tables, use *report_ocvm* command. To remove the converted POCV tables, use *remove_ocvm* command.

Multicorner-Multimode Support

By default, this command works on the current corner. To specify a different corner, use the *-corners* option.

Examples

The following example converts the AOCV tables for corner1.

```
prompt> convert_aocv_pocv -corners corner1
```

See Also

- read_ocvm
- report_ocvm
- remove_ocvm

---

convert_bump_region_to_freeform

Converts a structured bump_region into a freeform bump_region.

Syntax

collection *convert_bump_region_to_freeform*

```
-region region
[-freeform_pattern_name name]
```

Data Types

```
region              collection
name                string
```

Arguments

`-region region`

Specifies the bump_region to convert to freeform. The argument value must be a collection containing a single structured bump_region. A bump_region

Feedback

is structured if it references a bump_region_pattern with *type* attribute value "structured". Equivalently, a bump_region is structured if its *is_freeform* attribute value is "true".

This is a required argument.

`-freeform_pattern_name` *name*

Specifies the name of the new bump_region_pattern that will be created. This command creates a new freeform bump_region_pattern for the bump_region, to replace its current structured bump_region_pattern on conversion. This specifies what the name of the new bump_region_pattern should be. The name should be unique compared to the names of other bump_region_patterns in the block.

This is an optional argument. If unspecified, a unique name will be automatically generated.

Description

The *convert_bump_region_to_freeform* command converts an existing structured bump_region into freeform. A bump_region is structured if it references a structured bump_region_pattern. In structured bump_regions, its pseudo_bumps are implicitly generated based on the pitch and stagger specified in the bump_region_pattern, and pseudo_bump offsets are the offsets from the default pattern-based location of the bump. In freeform bump_regions, pseudo_bumps are explicitly created and removed by the user, and pseudo_bump offsets are from the lower-left origin of the bump_region.

This command will convert a structured bump_region into freeform, resulting in the same geometry and pseudo_bump layout, as though the user had instantiated pseudo_bumps in the same locations as the original structured state. However, the pseudo_bumps' offsets will be with respect to the lower-left origin of the bump_region, and the user will then be able to destroy one or more of the pseudo_bumps, or create new ones.

Since a bump_region is structured or freeform based on the bump_region_pattern it references, converting the bump_region from structured to freeform requires changing its referenced bump_region_pattern to a freeform one. This command will create a new freeform bump_region_pattern with the same non-layout attributes such as pseudo_bump shape and radius, and will set it as the referenced pattern of the converted bump_region.

Examples

The following example converts a bump_region named "BUMP_REGION0" from structured to freeform, with new freeform bump_region_pattern named "myFFpattern":

```
prompt> set r [get_bump_regions BUMP_REGION0]
{BUMP_REGION0}
prompt> get_attribute $r is_freeform
false
prompt> get_attribute $r pattern
{BUMP_REGION_PATTERN0}
```

Feedback

```
prompt> convert_bump_region_to_freeform -region $r -freeform_pattern_name
 "myFFpattern"
{BUMP_REGION0}
prompt> get_attribute $r is_freeform
true
prompt> get_attribute $r pattern
{myFFpattern}
```

See Also

---

convert_bump_terminals

Converts bump terminals from the net-based to the terminal-based bump connection model.

Syntax

collection *convert_bump_terminals*

```
[-check_only]
[-verbose]
```

Arguments

`-check_only`

Checks the ports and reports the ports that need to be converted, but does not modify any data.

`-verbose`

Prints additional messages indicating the ports that have been converted.

Description

This command converts each port, which currently has automatically created terminals following the net-based bump model, to have terminals following the terminal-based bump model.

Feedback

The conversion is based on the existing netlist connectivity and only applies to ports that are connected directly to a bump cell within the same physical hierarchy. If the top port is connected to a subblock and the subblock contains the bump cell, this command will convert the subblock's port but not the top port. The top port will continue to use the existing net-based bump model. The subblock's port will use the new terminal-based bump model, since it is directly connected to a bump pin.

For each port needing conversion, this command disconnects the corresponding bump pins from the net. However the port remains connected to the net.

Examples

The following example reports the ports that need conversion.

```
prompt> convert_bump_terminals -check_only
```

The following example converts all ports that need conversion and prints verbose messages.

```
prompt> convert_bump_terminals -verbose
```

See Also

- create_terminal

---

convert_shape_patterns_to_shapes

Converts shape_patterns to shapes in the current design.

Syntax

collection *convert_shape_patterns_to_shapes*

```
[-verbose]
[-force]
shape_pattern_list
```

Data Types

shape_pattern_list	collection

Arguments

`-verbose`

Display additional debugging information.

Feedback

`-force`

Ignore the locked status of objects. If this option is not provided and any of the affected objects has locked status, the command will generate a Tcl error and exit.

`shape_pattern_list`

Specifies a list of shape_patterns to convert and replace with shapes. The list can contain shape_pattern collections specified with the *get_shape_patterns* command.

Description

This command creates new shapes to replace the specified shape_patterns and returns a collection containing the new shapes.

Upon success the specified shape_patterns would be removed and their replacement shapes created by this command are returned.

Examples

The following example converts a shape_pattern to shapes.

```
prompt> convert_shape_patterns_to_shapes [get_shape_patterns
 RECT_PATTERN_31_0]
{RECT_31_1829 RECT_31_1830 RECT_31_1831 RECT_31_1832}
```

See Also

- create_shape
- get_shape_patterns
- get_shapes
- remove_shape_patterns
- remove_shapes

---

convert_shapes_to_shape_pattern

Converts shapes to shape patterns in the current design.

Syntax

collection *convert_shapes_to_shape_pattern*

```
[-base_shape     shape]
[-m_displacement delta]
[-n_displacement delta]
[-verbose]
```

Feedback

```
[-force]
[-shapes shapes]
[-region geometry]
[-layers layers]
[shape_list]
```

Data Types

```
base_shape    collection
delta         distance:direction | {x-distance:x-direction
                                    y-distance:y-direction}
distance      float
direction     string
shapes        collection
geometry      collection
layers        collection
shape_list    collection
```

Arguments

`-base_shape`

Specifies the shape in the input list that should be used as the base_shape at the first (0,0) position.

`-m_displacement`

Specifies the uniform offset in first dimension.

`-n_displacement`

Specifies the uniform offset in second dimension.

`-verbose`

Display additional debugging information.

`-force`

Ignores the locked status of objects. If this option is not provided and any of the affected objects has locked status, command will generate a Tcl error and exit.

`-shapes` *shapes*

Specifies a list of shapes to convert and replace with shape patterns. Shapes of use type PG augmentation are not allowed to be specified as input. The list can contain shape collections specified with the *get_shapes* command. The option "*shapes*" is mutually exclusive with "*region*", "*layers*" and "*shape_list*".

`-region` *geometry*

Specifies a list of regions to get shapes and convert and replace them with shape patterns. Shapes of use type PG augmentation are skipped. The option "*region*" is mutually exclusive with "*shapes*", "*layers*" and "*shape_list*".

Feedback

`-layers` *layers*

Specifies a list of layers to get shapes and convert and replace them with shape patterns. Shapes of use type PG augmentation are skipped. The option "*layers*" is mutually exclusive with "*shapes*", "*region*" and "*shape_list*".

shape_list

Specifies a list of shapes to convert and replace with shape patterns. Shapes of use type PG augmentation are not allowed to be specified as input. The list can contain shape collections specified with the *get_shapes* command. The option "*shape_list*" is mutually exclusive with "*shapes*", "*region*" and "*layers*".

Description

This command creates new shape patterns to replace the specified shapes and returns a collection containing the new shape patterns.

If the optional option *shape_list* is specified, all input shapes must have the same shape_type, owner net and uniform spacing. In case the order of shapes in input collection is different from the expected positional order of the shapes in the converted shape_pattern, the base_shape must be specified to guide the conversion. In case of non-uniform spacing between the input shapes caused by the absence of shape at any position, the user must provide the expected uniform spacing in both dimensions to guide the conversion. The tool would error violation of these requirements and abort the conversion.

The option "*shapes*" and "*layers*" and "*region*" are mutually exclusive with "*shape_list*" and useful for auto detection of via matrixes.

Examples

The following example converts all shapes to shape patterns.

```
prompt> convert_shapes_to_shape_pattern -shapes [get_shapes]
{RECT_PATTERN_31_0 RECT_PATTERN_31_1}
```

The following example converts specified shapes to a shape pattern.

```
prompt> convert_shapes_to_shape_pattern [get_shapes \\
                -filter {shape_type==rect && layer_name==M1}]
{RECT_PATTERN_31_0}
```

The following example converts shapes to a shape_pattern where the last shape in the input collection is used as the base_shape and the uniform displacements are specified to guide the conversion to shape_pattern with unoccupied (hole) positions.

```
prompt> convert_shapes_to_shape_pattern \\
                -base_shape [index_collection [get_shapes] end] \\
                -m_displacement {50:north} \\
                -n_displacement {20:east} \\
```

Feedback

```
                [get_shapes -filter {shape_type==rect &&
 layer_name==M1}]
{RECT_PATTERN_31_0}
```

---

convert_via_matrixes_to_vias

Converts via matrixes to vias in the current design.

Syntax

collection *convert_via_matrixes_to_vias*

```
[-verbose]
[-force]
via_matrix_list
```

Data Types

```
via_matrix_list     collection
```

Arguments

`-verbose`

Display additional debugging information.

`-force`

Ignore the locked status of objects. If this option is not provided and any of the affected objects has locked status, the command will generate a Tcl error and exit.

via_matrix_list

Specifies a list of via matrixes to convert and replace with vias. The list can contain via matrix collections specified with the *get_via_matrixes* command.

Description

This command creates new vias to replace the specified via matrixes and returns a collection containing the new vias.

Feedback

Upon success the specified via matrixes would be removed and their replacement vias created by this command are returned.

Examples

The following example converts a via matrix to vias.

```
prompt> convert_via_matrixes_to_vias [get_via_matrixes VIA_MATRIX_0]
{VIA_S_0 VIA_S_1 VIA_S_2 VIA_S_3 VIA_S_4 VIA_S_5}
```

See Also

- create_via
- get_via_matrixes
- get_vias
- remove_via_matrixes
- remove_vias

---

convert_vias_to_via_matrix

Converts vias to via matrixes in the current design.

Syntax

collection *convert_vias_to_via_matrix*

```
[-verbose]
[-force]
[-vias vias]
[-region geometry]
[-via_defs via_defs]
via_list
```

Data Types

```
via_list     collection
vias         collection
geometry     collection
via_defs     collection
```

Arguments

`-verbose`

Display additional debugging information.

Feedback

`-force`

Ignores the locked status of objects. If this option is not provided and any of the affected objects has locked status, command will generate a Tcl error and exit.

`via_list`

Specifies a list of vias to convert and replace with a via matrix. Vias of use type PG augmentation are not allowed to be specified as input. The list can contain via collections specified with the *get_vias* command. The option "*via_list*" is mutually exclusive with "*vias*", "*region*" and "*via_defs*".

`-vias` *`vias`*

Specifies a list of vias to convert and replace with via matrixes. Vias of use type PG augmentation are not allowed to be specified as input. The list can contain via collections specified with the *get_vias* command. The option "*vias*" is mutually exclusive with "*via_list*", "*region*" and "*via_defs*".

`-region` *`geometry`*

Specifies a list of regions to get vias and convert and replace them with via matrixes. Vias of use type PG augmentation are skipped. The option "*region*" is mutually exclusive with "*via_list*", "*vias*" and "*via_defs*".

`-via_defs` *`via_defs`*

Specifies a list of via_defs to get vias and convert and replace them with via matrixes. Vias of use type PG augmentation are skipped. The option "*via_defs*" is mutually exclusive with "*via_list*", "*vias*" and "*region*"

Description

This command creates new via matrixes to replace the specified vias and returns a collection containing the new via matrixes. If the optional option *via_list* is specified, the specified vias must be of the same via_def and via_type because the base via of the via matrix can be one of a simple, simple array, or custom via. If the specified vias don't have matching attributes for conversion to base via representation of a via matrix, the command would fail retaining the specified vias.

Upon success the specified vias would be removed and their replacement via matrix created by this command is returned. The option "*vias*" and "*via_defs*" and "*region*" are mutually exclusive with "*via_list*" and useful for auto detection of via matrixes.

Examples

The following example converts vias to a via matrix with a base simple via.

```
prompt> convert_vias_to_via_matrix [get_vias -filter {via_def_name==VIA23
 && via_type==simple_via}]
{VIA_MATRIX_0}
```

Feedback

The following example converts all vias to via matrixes.

```
prompt> convert_vias_to_via_matrix -vias [get_vias]
{VIA_MATRIX_0 VIA_MATRIX_1}
```

See Also

- create_via_matrix
- get_via_matrixes
- get_vias
- remove_via_matrixes
- remove_vias

---

copy_block

Copies a block to a new block in the same or a different library and view

Syntax

collection *copy_block*

```
[-force]
[-from_block  source_block]
-to_block   destination_block
```

Data Types

```
source_block       string
destination_block  string
```

Arguments

`-force`

Forces overwrite of the block specified by -to_block *block_name*. This option is used when the destination is open and modified but not yet saved.

`-from_block` *source_block*

Specifies the source block name with optional library, label, and view specifications. The *source_block* specification is as follows:

```
[libName:]blockName[/labelName][.viewName]
```

or a collection of one block. If the library specification is not present, the current library is used. If label specification is not present, then the default label is used. If the view specification is not present, the design view is used. By default, the *current_block* is used as the source.

Feedback

`-to_block` *`destination_block`*

Specifies the destination block name with optional library and view specifications. The *destination_block* specification is as follows:

```
[libName:]blockName[/labelName][.viewName]
```

If the library, block, or view specifications are not present, the values from the source block are used. This option is required.

Description

This command copies a source block to a destination with the same or different library and block. The destination block will have a mode attribute with a value of "a" and the destination block can be further modified without any change in open mode. If you try to copy a block over itself, the command issues an error message. The command also fails if the destination block is open and has been modified but not saved and the *-force* option is omitted. The command also fails if you specify an illegal name for the source or destination library, block, or view. If successful, the destination block is returned.

If the provided destination library is not present, the tool will create the destination on disk by cloning the source library. Once the copy is done, both the destination library and block will be present on disk for this kind of scenario.

This command returns the block if successful, or O if not. If an illegal name is given for the source or destination block names, a Tcl error is raised.

When no view is explicitly specified for both source and destination then all available views of source block are copied into destination block and the design view of destination block is returned.

A given source block view can't be copied into a different destination block view, like a design view can't be copied to an abstract view. An error is issued while trying to do such operation.

The copied destination block is by default available in memory only. This behavior can be controlled using app option *design.on_disk_operation* where setting the app option to true means copied destination block will be saved to disk.

The copied destination block doesn't become the current block. It needs to be explicitly set.

Examples

This example copies block *Top* in library *lib* to block *Top2* in same library for subsequent block exploration. The destination library and view are taken from the original block.

```
prompt> copy_block -from_block lib:Top -to_block Top2
{"lib:Top2.design"}
prompt> current_block lib:Top2
```

Feedback

If library *lib* is already open and is current library then using *-from_block Top* and *current_block Top2* in above example is sufficient.

This example copies a block *Top* in current library into a different existing library MyOtherDesigns for subsequent block exploration.

```
prompt> copy_block -from_block Top -to_block MyOtherDesigns:Top
{"MyOtherDesigns:Top.design"}
prompt> current_block MyOtherDesigns:Top
```

This example copies a block *Top* in current library into a different existing library MyOtherDesigns with a different name *Top2* and saves it to disk.

```
prompt> set_app_options -name design.on_disk_operation -value true
prompt> copy_block -from_block Top -to_block MyOtherDesigns:Top2
Information: Saving block 'MyOtherDesigns:Top2.design'
{"MyOtherDesigns:Top2.design"}
```

---

copy_busplan

Copy specified parts of busplan.

Syntax

int *copy_busplan*

```
[-from_start element]
[-from_end elements]
[-to_start element]
[-to_end elements]
[-from bus]
```

Feedback

Data Types

element	bus elements
elements	collection of bus elements
bus	bus

Arguments

`-from_start` *element*

Specify the starting bus element to copy from. This is mutually exclusive with -from.

`-from_end` *elements*

Specify the ending bus elements to copy from. This is mutually exclusive with -from.

`-to_start` *element*

Specify the starting bus element to copy to. This is mutually exclusive with -from.

`-to_end` *elements*

Specify the ending bus elements to copy to. This is mutually exclusive with -from.

`-from` *bus*

Specify the busplan to copy from. This will automatically determine the parts of the bus going through MIBs. It will determine the other MIB instances and the buses going through the other MIB instances. It will then copy the MIB section from the given bus to the other buses.

Note that all the buses must all be MIB port compliant. This means that all the buses must use the same ports in the MIB. For example suppose there are 2 MIBS, B1 and B2, and if there is feedthrough bus element corresponding to the ports B1/data[0..10] and there is a feedthrough bus element corresponding to the ports B2/data[0..10]. Then in this case these 2 MIB bus port sets are MIB port compliant. On the other hand if the feedthrough bus element is different, eg, corresponding to the ports B2/data[0..9] then that is not MIB port compliant.

Description

Copy busplan virtual pins, virtual registers, and location information. There are 2 mechanisms. First, it can be used to copy sub-sections of buses. Using the 4 options, "-from_start *element*", "-from_end *elements*", "-to_start *element*", "-to_end *elements*" a from sub-section and to sub-section can be defined. Then copy will copy from the from sub-section to the to sub-section.

A second mechanism is using option "-from *bus*" and this is used to ensure busplans inside MIBs are the same.

Feedback

Examples

This example shows copying a section of bus bus1 to another bus, bus2. The section of bus1 to copy is starting from bus element bus1:group2 and going to bus1:group3. This section will be copied to the section of bus2 starting from bus element bus2:group3 and going to bus2:group4.

```
prompt> copy_busplan -from_start [filter_collection \\
   [get_attribute [get_busplan bus1] elements] name==group2] \\
   -from_end [filter_collection \\
      [get_attribute [get_busplan bus1] elements] name==group3] \\
   -to_start [filter_collection \\
      [get_attribute [get_busplan bus2] elements] name==group3] \\
   -to_end [filter_collection \\
      [get_attribute [get_busplan bus2] elements] name==group4]
1
```

- set_net_estimation_rule

---

copy_collection

Duplicates the contents of a collection, resulting in a new collection. The base collection remains unchanged.

Syntax

collection *copy_collection*

collection1

Data Types

collection1 collection

Arguments

collection1

Specifies the collection to be copied. If an empty string is used for the *collection1* argument, the command returns the empty string (a copy of the empty collection is an empty collection).

Feedback

Description

This command is no longer needed and is provided only to make old scripts work without modification.

Examples

The following example from PrimeTime shows the result of copying a collection. Functionally, it is not much different that having multiple references to the same collection, except it is slower.

```
pt_shell> set c1 [get_cells "U1*"]
{"U1", "U10", "U11", "U12"}
pt_shell> set c2 [copy_collection $c1]
{"U1", "U10", "U11", "U12"}
pt_shell> unset c1
pt_shell> query_objects $c2
{"U1", "U10", "U11", "U12"}
```

See Also

- collections

---

copy_floorplan

Copies the floorplan data from the design view of source design label to the design view of the target design label in the same or a different library.

Syntax

collection *copy_floorplan*

```
[-to_block top_block]
-from_block from_top_block
[-objects objects]
[-include include_list]
[-exclude exclude_list]
[-hierarchical]
[-force]
[-verbose]
```

Data Types

top_block	string
from_top_block	string
objects	collection
include_list	list
exclude_list	list

Feedback

Arguments

`-force`

Forces copying of those floorplan objects of source block to the destination block even if they already exist. To check existing floorplan objects, names are matched. In the default mode, matching objects are not copied.

`-from_block` *`from_top_block`*

Specifies the source design label name with optional library, block and label specifications. The *from_top_block* specification is as follows:

```
[libName:]blockName[/labelName]
```

If the library specification is not present, the current library is used. If label specification is not present, then the default label is used. This is a required option.

`-to_block` *`top_block`*

Specifies the destination design label name with optional library and label specifications. The *top_block* specification is as follows:

```
[libName:]blockName[/labelName]
```

If the library, block, or label specifications are not present, the values from the source block are used. By default, the *current_block* is used as the destination.

`-include` *`include_list`*

Specifies the types of floorplan data to copied to the output design view. This option cannot be specified together with the *-exclude* or *-objects* options. If this option is not specified, all types are included by default.

The supported types are:

- blockages
- bounds
- cells
- corridors
- die_area
- edit_groups
- io_guides
- macros
- module_boundaries

Feedback

- pin_guides
- pins
- route_guides
- rows
- tracks
- vias
- scan_chains
- routing_directions
- voltage_areas
- fills
- pg_metal_fills
- routing_rules
- pg_regions
- port
- supernet
- bundle
- topology_plan
- net_estimation_rule

Specify *-include macros* to output only macro cells and skip standard cells. Specify *-include cells* to output all cells.

`-exclude` *`exclude_list`*

Specifies the types of data to exclude from the output. This option cannot be specified with the *-include* option or *-objects* options. If this option is specified, the command writes all types, except the types specified in *exclude_list*. The allowed data types are the same as for the *-include* option.

`-objects` *`objects`*

Specifies the floorplan objects to be copied to the destination design view. Supported object types are:

- "block"
- "design"

Feedback

- "routing_blockage"
- "shaping_blockage"
- "placement_blockage"
- "bound"
- "cell"
- "routing_corridor"
- "core_area"
- "edit_group"
- "fill_cell"
- "io_guide"
- "via"

- "site_row"
- "site_array"
- "track"
- "voltage_area"
- "routing_rule"
- "port"
- "supernet"
- "bundle"
- "topology_plan"

`-verbose`

This option enables display of verbose messages.

Feedback

`-hierarchical`

This option enables copying of the floorplan objects hierarchically. This option is mutually exclusive with "*-objects*".

Description

This command copies the floorplan data from the design view of source design label to the design view of the target design label with the same or different library and block. The command fails if the destination library is not open or is opened in read-only mode. The command also fails if you specify an illegal name for the source or destination design label or if the design view is not available for a particular design label. If successful, the destination block is returned.

This command returns the block if successful, or O if not. If an illegal name is given for the source or destination block names, a Tcl error is raised.

The operation happens only between design views. If the destination design is not specified, the current block is used as the destination design if the view is design view.

The command only copies the floorplan objects which exist in the source but not in the destination. To find whether a particular floorplan object exists, the name is matched. If the name of a particular floorplan object already exists, the object is skipped and is not copied. This can be overriden by specifying the *-force* option.

Examples

This example copies floorplan data of design view of design label *Top* to design view of block *Top2*. Only the floorplan objects not present in Top2 are copied.

```
prompt> copy_floorplan -from_block lib:Top/place_opt -to_block
 lib:Top2/place_opt
{"lib:Top2.design"}
```

This example copies a block Top into a new library MyOtherDesigns. Only the floorplan objects not present in Top2 are copied MyOtherDesigns:TOP\place_opt.

```
prompt> copy_floorplan -from_block lib:Top/place_opt -to_block
 MyOtherDesigns:TOP\place_opt

{"MyOtherDesigns:Top.design"}
```

- save_block

---

copy_lib

Copies one or more design libraries from one location to another.

Syntax

collection *copy_lib*

```
[-force]
[-merge | -no_designs]
[-from_lib source_name]
-to_lib destination_name
```

Data Types

```
source_name         collection
destination_name    string
```

Arguments

`-force`

Overwrites the destination library when the library is modified but not yet saved. If this option is not specified, the command stops and issues an error message if the library is modified but not yet saved.

`-merge`

Merges the source library into the destination library. This option is used for incremental update. Normally, the destination library is (re)initialized before the copy begins. This option can be used only if both the source and destination libraries are design libraries. Note that lib-cell libraries cannot be merged, and library attributes, technology, and parasitic_tech data are not merged. If the destination library does not already contain technology or parasitic_tech data, the command copies the technology or tech_parasitic data from the source library to the destination library. Only libraries with compatible technology can be merged, and the command performs a technology compatibility test if both the source and destination libraries contain technology sections. The *-merge* option fails if the source and destination technologies are incompatible.

`-no_designs`

Copies the source library to the destination library, without copying the designs in the source library. This option is mutually exclusive with the *-merge* option. The command copies the library attributes, ref_lib list, view_switch list,

Feedback

technology, and parasitic_tech from the source library without copying any of the designs. This option is useful when splitting a source library that contains subblocks into a separate destination libraries that each contain a subblock.

`-from_lib` *`source_name`*

Specifies the source library. You can specify either a list of library names or a collection of libraries. If you specify a list or collection of multiple libraries, the designs in each library are copied to the destination library. If there are duplicate designs in the source libraries, the design from the first library in the list that contains the duplicate is copied to the destination library. If the *-no_designs* option is used, the *-from_lib* option must contain a single library. If this option is not specified, the command uses the current library. Use the *current_lib* command to determine the current library.

`-to_lib` *`destination_name`*

Specifies the destination library name.. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after he last '/' becomes the name of the library. It will be an error if the a library, file, or directory of the same name already exists on disk.

Description

This command copies one or more source libraries into a destination library. If technology data and a ref_lib list exists, they are copied as well. Note that the command fails if there are conflicts in technology data among the source libraries or between the source and destination libraries when the *-merge* option is used. When there are conflicts in design data, the data from the first library in the source list is used (or from the destination library if the *-merge* option is used and a conflict exists). Note that conflicts are resolved on the design level, not down to the view level. For example, if a source library has topLib1:Mid.timing and another source library has topLib2:Mid.design, only the first design is copied. The destination target is reinitialized (deleted) before the copy unless the *-merge* option is used. When the source and destination libraries contain a reference library list, the source reference list is appended to the target library and the duplicate entries are removed.

The command returns the library if successful, or 0 otherwise. If an illegal name is given, a Tcl error is raised.

Note that when overriding an existing library (without the *-merge* option), there is no automatic rebinding to the new design or technology data in the library. All original designs in the library are removed, and designs from other libraries that used to bind to those removed designs become unbound. Any other libraries or designs that used to bind to the technology data of the overridden library are also be unbound and are saved without a technology section.

Feedback

It is also an error to copy (or merge) from (or into) lib-cell library. It is also an error to copy over a library that is opened for read-only, or to copy over a library that has unsaved and modified data without using the *-force* option.

Examples

The following example copies library lib1 into the library design_lib.

```
prompt> copy_lib -from_lib "lib1" -to_lib design_lib
{"design_lib"}
```

The following example copies the designs from lib1 and lib2 into the library top_lib.

```
prompt> copy_lib -from_lib "lib1 lib2" -to_lib top_lib
{"top_lib"}
```

The following example merges the designs from lib1 and lib2 into the library mid_lib, without reinitializing mid_lib

```
prompt> copy_lib -merge -from_lib "lib1 lib2" -to_lib mid_lib
{"mid_lib"}
```

The following example copies the technology and ref_lib list from lib1 to lib2 without copying the designs.

```
prompt> copy_lib -no_designs -from_lib "lib1" -to_lib lib2
{"lib2"}
```

copy_module

Copies a module in a design

Feedback

Syntax

collection *copy_module*

```
[-design design]
-from module
-to to_module]
[-force]
```

Data Types

```
design     string or collection
module     string or collection
to_module  string
```

Arguments

`-design design`

Specifies the design in which to copy the module. If not specified, then module is copied in the current design.

`-from module`

Specifies source module to be copied, as a string or collection. If specified as a string then it is searched in current design.

`-to to_module`

Specifies destination module name.

`-force`

Forces overwrite of the module specified by *-to* only if it is not the top module of its design and is not instantiated anywhere.

Description

This command copies a specified module to a destination design provided it doesn't already exist. If it already exists in destination then *-force* can be used to overwrite the module provided it is not instantiated anywhere and is not the top module.

A module is hierarchically copied over to the destination. Thus this command can result in copying over many modules into destination. If the module is copied over to a different library then it is checked that reference library of destination library is a subset of reference library of source library. Otherwise the command will fail.

---

copy_objects

Copies specified objects and creates multiple copies if specified.

Syntax

status *copy_objects*

```
[-delta {x y}]
[-from {x y}]
[-to {x y}]
[-to_objects object_list]
[-x_offset x_offset]
[-y_offset y_offset]
[-rotate_by angle]
[-group]
[-x_times x_times]
[-y_times y_times]
[-x_pitch x_pitch]
[-y_pitch y_pitch]
[-x_pitch_type gap | delta]
[-y_pitch_type gap | delta]
[-net net]
[-plan topology_plan]
[-trace_connectivity]
[-simple]
[-keep_non_signal_nets]
[object_list]
```

Data Types

```
x             float
y             float
object_list   collection or selection
x_offset      float
y_offset      float
angle         string
x_times       integer
y_times       integer
x_pitch       float
y_pitch       float
net           collection
topology_plan collection
```

Feedback

Arguments

`object_list`

Specifies a collection or selection set that contains objects to copy. If this option is not specified, the global selection set is used.

`-delta {x y}`

Specifies the distance in the x- and y-directions which to copy the objects from their current location. This option is mutually exclusive with the *-to* option.

`-from {x y}`

Specifies the reference point on the object, or the collection of objects to be copied, for the *-to* or *-to_objects* option. By default, the command uses the lower-left corner of the bounding box of the given object, or collection of objects, as the reference point, when this option specified with the *-to* option. By default, the command uses the most left-bottom origin of the given objects, or collection of objects, as the reference point, when this option specified with the *-to_objects* option.

`-to {x y}`

Specifies the new x- and y-location of the reference point for the object or objects. This option is mutually exclusive with the *-delta*.

`-to_objects {object_list}`

Specifies a collection or selection set of target objects. The origins of these objects are used as the target locations for the copies. If an object does not have a defined origin, the center of its bounding box is used. When using *-to_objects*, the reference point for the copied objects can be specified with *-from*.

`-x_offset {x_offset}`

Specifies an additional offset in the x-direction to be applied to each target location calculated by *-to_objects*.

`-y_offset {y_offset}`

Specifies an additional offset in the y-direction to be applied to each target location calculated by *-to_objects*.

`-rotate_by angle`

Specifies the rotation angle of the objects.

The valid values are:

```
0,      90,     180,    270,     CW90,
CW180,  CW270,  CCW90,  CCW180,  CCW270,
```

Feedback

```
FLIPX,  FLIPY   R0,     R90,     R180,
R270,   MX,     MXR90,  MY,      MYR90
```

The rotation value definitions are:

```
CW90   : 90 degrees clockwise
CW180  : 180 degrees
CCW180 : 180 degrees
CW270  : 270 degrees clockwise
CCW90  : 90 degrees counterclockwise
CCW270 : 270 degrees counterclockwise
FLIPX  : reflect about the x-axis
FLIPY  : reflect about the y-axis
```

The following values are synonymous:

```
0,   R0
90,  CCW90,  R90
180, CCW180, R180
270, CCW270, R270
FLIPX, MY
FLIPY, MX
```

`-group`

Specifies that the objects should rotate around a common pivot point. If omitted, the rotation is performed around the object centers. The pivot point could be specified by *-to* option. In case *-delta* option is used, the common center would become the pivot point.

`-x_times` *x_times*

Specifies the number of copies in x-direction.

`-y_times` *y_times*

Specifies the number of copies in y-direction.

`-x_pitch` *x_pitch*

Specifies the delta or gap in x-direction.

`-y_pitch` *y_pitch*

Specifies the delta or gap in y-direction.

`-x_pitch_type gap | delta`

Specifies the x pitch as delta or gap. Legal values are gap or delta.

`-y_pitch_type gap | delta`

Specifies the y pitch as delta or gap Legal values are gap or delta.

Feedback

`-net` *net*

Specifies the net for the copied object.

`-plan` *topology_plan*

Specifies the topology plan for the copied object.

`-trace_connectivity`

Trace the electrical connectivity of metal routes, vias, bumps and TSVs to connect nets to objects. Only newly created objects can be connected by using this option.

`-simple`

Disable snapping and editing constraints. By default, objects are snapped according to global snap settings. Snap settings can be accessed using *get_snap_setting*.

`-keep_non_signal_nets`

Keep the non-signal nets of the copied objects.

Description

This command copies one or more objects and returns a collection of the copies if input *object_list* is a collection of objects. Otherwise, the command adds copies in specified selection set and returns the status.

You can place the copies at a specific location or specify a delta from the location of the original object, or use the origins of target objects specified by *-to_objects*. If *-to_objects* is used, the origins of the target objects are calculated (using the object's origin if available, otherwise the center of its bounding box). You can also specify additional offsets using *-x_offset* and *-y_offset* to shift the target locations.

You can create multiple copies of each specified object, and you can specify the pitch between adjacent copies of the same object.

All the attributes of an original object are applied to its copies if possible.

Examples

The following example copies the selected object and places the copy 100 database units to the right and 200 database units above the original object:

```
prompt> copy_objects -from {0 0} -to {100 200}
```

The following example creates 8 copies of the selected object placed in a 2 by 4 grid with delta (100,100) and no space between the objects.

```
prompt> copy_objects -from {0 0} -to {100 100} -x_times 2 -y_times 4
```

Feedback

The following example uses an alternative syntax to specify the objects.

```
prompt> copy_objects [get_selection] -from {0 0} -to {100 100} -x_times 2
 -y_times 4
```

The following example copy objects to the origins of a set of target objects, using the most left-bottom origin of the copied objects as the reference point:

```
prompt> set target_objects [get_shapes {RECT_16_589 RECT_16_588}]
prompt> copy_objects -to_objects $target_objects
```

The following example copy objects to the origins of a set of target shapes, with an additional offset of 10 units in x and 20 units in y:

```
prompt> set target_objects [get_shapes {RECT_16_589 RECT_16_588}]
prompt> copy_objects [get_selection] -to_objects $target_objects
 -x_offset 10 -y_offset 20
```

The following example copy objects to the origins of a selected target shapes, using the {0 0 } as the reference point for the copied objects :

```
prompt> set objects [get_shapes {RECT_16_589 RECT_16_588}]
prompt> copy_objects $objects -from {0 0} -to_objects [get_selection]
```

---

copy_relative_placement

Copies the relative placement of macros.

Syntax

collection *copy_relative_placement*

Feedback

```
-from edit_group
[-to edit_group_list]
[-to_cells cell_list]
```

Data Types

```
edit_group      string
edit_group_list list
cell_list       list
```

Arguments

`-from edit_group`

Specifies the edit group from which to copy the relative placement.

`-to edit_group_list`

Specifies a list of edit groups; relative placement will be copied to each edit group in the list.

`-to_cells cell_list`

Specifies a list of cells to which to copy the relative placement. The tool creates an edit group for these cells.

Description

This command copies macro relative locations from one edit group to another edit groups or a collection of macros. At least one of *-to* and *-to_cells* must be provided. Use this command to arrange the corresponding macros from similar modules in the same way. The command returns the collection of edit groups passed as *-to* argument and/or the edit group created for *-to_cells* argument.

Examples

The following example copies relative placement from edit group E1 to edit groups E2 and E3.

```
prompt> copy_relative_placement -from [get_edit_groups E1] -to
 [get_edit_groups {E2 E3}]
```

The following example copies relative placement from edit group E to the selected macros.

```
prompt> copy_relative_placement -from [get_edit_groups E] -to_cells
 [get_selection]
```

- create_edit_group

Feedback

copy_to_layer

Creates shapes on a layer corresponding to a geometric region.

Syntax

collection *copy_to_layer*

```
-layer layer
-geo_masks geo_masks
[-shape_use use]
[-net net]
```

Data Types

```
layer          collection
geo_masks      collection
use            string
net            collection
```

Arguments

`-layer layer`

Specifies the layer on which the shapes should be created. There must be exactly one layer in this input collection.

This is a required option.

`-geo_masks geo_masks`

Specifies the objects that define the geometric region to be mapped to shapes on the specified layer. If the value of the *-shape_use* option is set to detail_route, one shape is created on the layer for each contiguous poly-rectangular region contained in the collection of geo_masks. If the value of the *-shape_use* option is set to stripe, then one shape is created on the layer for each rectangle in the rectangular decomposition (fracture) of the collection of geo_masks.

This is a required option.

`-shape_use use`

Specifies the usage of the shapes created by the command.

Valid values are

- *detail_route* (the default)

  Shapes are used for detail routed signal nets. They are of type rectangle or polygon.

- *stripe*

Feedback

Shapes that belong to a power strap. They are of type path.

- *pg_augmentation*

  Shapes for PG augmentation. They are of type path.

- *user_route*

  User-routed shapes. They are of type path.

- *lib_cell_pin_connect*

  Lib_cell pin connect shapes. They are of type path.

`-net` *net*

Specifies the net that owns the resulting shapes.

Description

This command creates shapes on the specified layer corresponding to a specified geometric region.

When the *-shape_use* option is set to detail_route or is unspecified, then a shape is created for each contiguous poly-rectangular region described by the *-geo_masks* option. For each such region, if it is rectangular and manhattan-angled then a rectangle is created, otherwise a polygon is created.

When the *-shape_use* option is set to stripe, pg_augmentation, or user_route, then a path shape is created for each rectangle in the rectangular decomposition (fracture) of the poly-rectangular region described by *-geo_masks* option. The orientation of the paths must match the routing direction of the specified layer, or is horizontal if the routing direction is unknown.

The new shapes created are returned as a collection.

Examples

The following example creates a rectangle on a layer:

```
prompt> set pr [create_poly_rect -boundary {{0 0} {200 100}}]

{{{0.0000 0.0000} {200.0000 100.0000}}}

prompt> set new_shapes [copy_to_layer -layer [get_layers M1] \\
   -geo_masks [create_geo_mask -objects $pr]]

{RECT_10_0}
```

Feedback

- split_polygons
- get_shapes
- transform_polygons

---

copy_useful_skew

Copies useful skew to newly added scenarios for consistent timing reports.

Syntax

status *copy_useful_skew*

```
[-no_user_bp]
```

Arguments

`-no_user_bp`

Ignore user-defined delay balance points when copying.

Description

When a pin has CTS balance point offsets defined in only a subset of the active scenarios, the command copies the offset to the scenarios where the offset is missing. To do so, the average value of the offset, scaled to the CTS reference corner, is computed across all scenarios where a balance point offset is defined, and that value is scaled back in each active scenario using the scaling factor of the scenario corner. The command also ensures that corresponding set_clock_latency constraints are set on all pins and scenarios where a new offset value is computed. Flow commands such as place_opt or compile_fusion run this command under the hood in order to ensure that previously defined offsets are available across all active scenarios. Use this command after enabling new scenarios when you want to generate timing or QoR reports using commands which do not call copy_useful_skew under-the-hood, like report_timing.

Feedback

See Also

- place_opt
- compile_fusion
- report_timing

---

cputime

Retrieves the overall user time associated with the current process.

Syntax

float *get_cputime*

```
[-all]
[-format]

string format
```

Arguments

`all`

If specified then it gives cpu time for this process and it's children.

`format`

This argument takes a *printf* style formatting string for a floating point number.

Description

The *get_cputime* command returns the accumulated user time, in seconds, for the current process. If the *format* string is omitted, an integer number of seconds is returned. If the format string is specified, a floating point number is returned. The number includes fractions of a second elapsed and is formatted in accordance with given specifier. Refer to the Unix man page for *printf* for a detailed description of how to format a floating point argument.

```
prompt> get_cputime "%g"
3.74
```

Feedback

create_3d_mirror_bumps

Copies and places bumps and bump clusters or bond pads from the source die to the target die.

Syntax

status *create_3d_mirror_bumps*

```
-from source_chip_name
-to target_chip_name
[-ref_cell lib_cell]
[-prefix prefix_name]
[-bumps bump_list]
[-cluster_bump_mapping pattern_cell_pair_list]
[-bond_pad]
[-bond_pad_list bond_pad_list]
[-pins pin_list]
[-bump_region]
[-bump_region_list bump_region_list]
[-pseudo_bump_list pseudo_bump_list]
[-to_bump_region bump_region_list]
[-force]
[-strip_away_prefix prefix_name]
[-bond_pad_def bond_pad_def_name]
[-bump_cluster_list edit_group_list]
[-no_snap]
[-skip_physical_check]
[-use_port_names]
[-top_nets net_list]
[-group_to_one]
[-offset offset]
[-naming_style format_list]
[-propagate_user_attributes]
[-boundary boundary_spec]
[-bump_mapping_file file_name]
```

Data Types

source_chip_name	string
target_chip_name	string
lib_cell	string
prefix_name	string
bump_list	list
pattern_cell_pair_list	list
pin_list	list
bond_pad_list	list
bump_region_list	list
pseudo_bump_list	list
bond_pad_def_name	string
edit_group_list	collection
net_list	collection

Feedback

```
offset                  float_pair
format_list             string
boundary_spec           float
file_name               string
```

Arguments

`-from` *source_chip_name*

Specifies the source chip or sub-block in chip as a master die. This option is required.

`-to` *target_chip_name*

Specifies the target chip or sub-block in chip as a slave die. This option is required.

`-ref_cell` *lib_cell*

Specifies the library cell or design_block. The cmd will search the ref_cell from target die's library and reference libraries, if there are multiple lib_cell or design_block in different reference libraries have the same name, please specify full design name to ease the ambiguity. This option is required for bump and cannot be specified with the *-bond_pad* option.

`-prefix` *prefix_name*

Specifies the prefix of the target mirrored objects.

`-bumps` *bump_list*

Specifies the bump list in source chip to be mirrored. By default, all bumps are mirrored.

`-cluster_bump_mapping` *pattern_cell_pair_list*

Specifies the bump cluster pattern cells in source chip and target chip. The pattern cell pair list is specified as {{source_pattern_cell target_pattern_cell} {} ...}. This option cannot be specified with the *-bond_pad* option.

`-bond_pad`

Mirrors bond pads from source chip to target chip.

`-pins` *pin_list*

If source chip is a hard macro, this option can be used to specify the pin list in the source chip to be mirrored. By default, all pins will be mirrored if the source chip is a hard macro.

`-bond_pad_list` *bond_pad_list*

Specifies the bond pad list in source chip to be mirrored. By default, all bond pads are mirrored.

Feedback

`-bump_region`

Mirrors bump regions from source chip to target chip. This option is required for pseudo bumps and cannot be specified with the *-bond_pad* option.

`-bump_region_list` *`bump_region_list`*

Specifies the bump region list in source chip to be mirrored. By default, all bump regions are mirrored. This option must be specified with the *-bump_region* option.

`-pseudo_bump_list` *`pseudo_bump_list`*

Specifies the pseudo bump list in source chip to be mirrored. The tool will create a freeform bump region to coverr these mirroed pseudo bumps. This option cannot be specified with the *-bump_region* option.

`-to_bump_region` *`bump_region_list`*

Specifies the target bump region in target chip to be mirrored the specifed pseudo bumps. This specified bump region must be freeform type. This option must be specified with the *-pseudo_bump_list* option.

`-force`

Specifies whether to mirror the objects if there are overlaps.

`-strip_away_prefix` *`prefix_name`*

Strip away the prefix of source bump name. The design already has source bumps prefixed with ${strip_prefix}, and the tool would like to remove the prefix from destination bump without changing name of source bump. If the name of target bump is empty after striping away prefix, the command will use "SYNOPSYS" as default.

`-bond_pad_def` *`bond_pad_def_name`*

Specifies the name of bond pad def, the bond pad def will be used to create bond pad, this option must be used with “-bond_pad”.

`-bump_cluster_list edit_group_list`

Specified the bump clusters from source chip to target chip.

`-no_snap`

Prevent snapping to grid when mirroring.

`-skip_physical_check`

Skip checking the bump face when mirroring the bump cells from one die to another die. When this option is specified, the command doesn't require the source die and target die are vertical neighboring, and mirrors the source bumps/bond_pads/pseudo_bumps that faced to target die if "-bumps/-

Feedback

bond_pad_list/-bump_region_list" is not specified. If "-bumps/-bond_pad_list/-bump_region_list" is specified with this option, the command mirriors all the specified objects without checking their bump face.

`-use_port_names`

Rename the mirrored bump name using its connected port if it is existed.

`-top_nets` *`net_list`*

Choose the source bumps/bond_pads that connect to the specified top nets to mirror.

`-group_to_one`

These bumps that connect to one top net will be mirrored to one bump, the location of target bump is the center of group of source bumps. It must be used with "-top_nets" option.

`-offset` *`offset`*

Specifies the offset value from center of from_object to center of to_object.

`-naming_style` *`format_list`*

Specifies the name style, including source_die_io_port and io_port: Values: connect_die_port, io_port, source_die_io_port. Connect_die_port: the target mirror bump will be named with the port name which connect t o source bump, it’s same with the behavior of option “-use_port_name”. Io_port: the target mirror bump will be named with "IOportName". Source_die_io_port: the target mirror bump will be named with "sourceDieName_IOportName".

`-propagate_user_attributes`

Propagate user attributes from source bumps to mirrored bumps.

`-boundary` *`boundary_spec`*

Specifies the boundary, these bumps that are fully covered with the specified boundary of source chip will be mirrored.

`-bump_mapping_file` *`file_name`*

Specifies the bump mapping CSV filename. Mirror bumps per the specification of “Source Bump Name”, “Target Bump Name”, “Target Bump Reference” in input mapping file. If the csv file has header, it allows users to change the data order; if the scv file doesn't have file herader, data order is fixed as "Source Bump Name,Source Bump Reference,Source Port Name,Source Net Name,Target Bump Name,Target Bump Reference,Target Port Name,Target Net Name". This option cannot be specified with the *-ref_cell*, *-bumps*, *-bond_pad*, *-bond_pad_list*, *-bond_pad_def*, *-pins*, *-bump_cluster_list*, *-cluster_bump_mapping*, *-prefix*, *-naming_style*, *-top_nets*, *-bump_region*, *-pseudo_bump_list*, *-boundary* options.

Feedback

Description

This command copies and places bumps and bump clusters or bond pads from the source die to the target die when the dies are stacked vertically. Hierarchy bumps are supported.

Examples

The following example copies bump cells from chip "Logic" to chip "Interposer" with the library cell "UBUMP", using the prefix "synopsys".

```
prompt> create_3d_mirror_bumps -from Logic -to Interposer \\
   -ref_cell UBUMP -prefix synopsys
```

The following example copies bump cluster which has pattern cell "BUMP8" from chip "Logic" to chip "Interposer" with pattern cell "BUMP4".

```
prompt> create_3d_mirror_bumps -from Logic -to Interposer \\
   -cluster_bump_mapping {{BUMP8 BUMP4}}
```

See Also

- set_cell_location

---

create_3d_virtual_blocks

Creates virtual interface blocks.

Syntax

collection *create_3d_virtual_blocks*

```
[-design design]
[-blocks { { die1[:num_layers] die2[:num_layers] }... }]
[-layers num_layers]
[-in_netlist]
[-die_separation separation_value]
```

Data Types

design	collection
die1	string
num_layers	integer
die2	string
separation_value	float

Arguments

`-design` *design*

Specifies the design in which to create the virtual interface blocks. If no design is specified, the virtual interface blocks are created in the current design.

Feedback

`-blocks { { die1[:num_layers] die2[:num_layers] }... }`

Specifies the die cells between which to create the virtual interface block. One or more pairs of die cell names can be specified. The number of routing layers to copy from each die can be specified after each name, which overrides the value specified by the *-layers* option.

`-layers num_layers`

Specifies the number of routing layers to copy from each die. If not specified, three layers are copied from each die. This can be overridden on a per-die basis in the *-blocks* specification.

`-in_netlist`

Connects the virtual interface blocks to the top netlist between the dies. If not specified, the virtual interface blocks are not connected to the top netlist.

`-die_separation separation_value`

Specifies the die separation distance used for micro bumps in the virtual interface blocks.

Description

This command creates virtual interface blocks between the specified dies or interposer cells. If no dies or interposer cells are specified, this command creates virtual interface blocks between all die and interposers in design which have their z-offset values set.

Examples

The following example creates virtual interface blocks between all dies and interpose in the design based on their z-offset values. The virtual interface blocks are connected to the top netlist.

```
prompt> create_3d_virtual_blocks -in_netlist
```

The following example creates a virtual interface block between two dies containing four routing layers from each die.

```
prompt> create_3d_virtual_blocks -blocks {die1 die2} -layers 4
```

The following example creates a virtual interface block between two dies containing two routing layers from the first die and three routing layers from the second die.

```
prompt> create_3d_virtual_blocks -blocks {die1:2 die2:3}
```

See Also

- remove_3d_virtual_blocks

Feedback

create_abstract

Creates abstract view of designs.

Syntax

```
status create_abstract
[-placement]
[-estimate_timing]
[-timing_level none | boundary | compact | full_interface]
[-host_options host_option_name]
[-work_dir path]
[-blocks block_designs]
[-all_blocks]
[-force_recreate]
[-read_only]
[-include_objects {include_objects_collection}]
[-target_use implementation | planning]
[-preserve_block_instances true | false]
```

Data Types

```
block_designs  list
include_objects_collection  collection of ports, pins and nets
```

Arguments

`-placement`

Creates the abstract view with no timing information. When this option is specified, the tool will not trace timing paths to the ports of the design. Instead, the tool examines the logical hierarchy of the design, and creates an abstract view with the necessary netlist data for top-level global placement. If the design has timing constraints loaded, constrained objects in the interface logic will be included in the placement abstract. A placement abstract is always editable. So this option overrides *-read_only*. By default, the generated abstract view contains timing information.

`-estimate_timing`

Run the *estimate_timing* command on interface logic and incorporate the estimated timing result in the abstract view.

`-timing_level none | boundary | compact | full_interface`

Specifies the amount of timing detail to include in the abstract. Abstracts with less detail require less memory and CPU.

Feedback

You can select one of three timing levels:

- *none* : The abstract excludes timing information at the top level. This is the default abstract type when *-placement* is specified.

  Use this abstract for pure physical operations (all design planning steps prior to *estimate_timing*, doing some purely physical operations at top-level).

  The value 'none' is deprecated and will be removed in a future release.

- *boundary* : The abstract includes minimal netlist ensuring connectivity of block ports to the first level of logic. Pure feedthrough, clock combinational feedthrough and internal clock path driving output port are retained

  Use this abstract for better transition fixing of the top level segment of boundary nets when abstract is linked to top.

- *compact* : The abstract includes timing information for all critical setup and hold paths at the boundary of the original design. When the abstract is instantiated at the top level, you can use the abstract to show the best and worst timing through any input port or output port of the abstracted design. These abstracts have a very high level of compression when compared to the full design, and have significant runtime and memory benefits. This is the default when *-placement* is not specified.

  When you build a "compact" timing abstract, it is necessary to evaluate timing paths in the design that is being abstracted. Because of this, you should have the following SDC constraints defined in your block, prior to creating the "compact" abstract:

  - All clocks and all generated clocks

  - All set_case_analysis and set_disable_timing

  - All exception constraints (*set_false_path*, *set_multicycle_path*) that affect timing paths that enter or leave the block.

  Use this abstract for all top-level implementation flows.

- *full_interface* : The abstract includes timing information for almost all paths at the boundary of the original design. Because all boundary paths are represented, it is not necessary to prepare a full SDC file for the original design before creating the abstract. However, you should have the following SDC constraints defined in your block before creating the "full_interface" abstract:

  - All clocks and all generated clocks

  "Full_interface" abstracts contain nearly all of the boundary logic in the original design; some boundary logic is filtered out to reduce the abstract

Feedback

size. In particular, logic connected only to high-fanout networks is filtered. Usually, the filtered logic includes clock networks, scan enable, and reset. For these signals, only the essential part of the logic is kept. You can control the filtering of high-fanout networks by setting the "abstract.high_fanout_limit" app option.

Use this abstract when your block SDC is not ready.

`-host_options host_option_name`

Specifies that the given host option should be used for distributed processing. If not specified, the tool will look for the global host option and use the global host option if it has distributed processing settings.

When *-blocks* or *-all_blocks* is specified, the tool might need to create abstract view for more than one block. Some of the blocks can run at the same time, depending on the hierarchy nesting.

`-work_dir` *`path`*

Specifies the directory to put all generated scripts and log files. This option is only used when *-blocks* or *-all_blocks* is specified. When *-blocks* or *-all_blocks* is specified, the tool need to create abstract view for one or more child blocks of the current block. Scripts and log files are generated for abstract view creation at the child blocks' level. The tool puts all the scripts and log files under a directory on disk.

If this option is not specified, the *work_dir* setting for the specified host option would be used. If no *-host_options* is specified, the *work_dir* of the global host option would be used. If there is no global host option and no *-host_options* is specified, the default is *./work_dir*.

`-blocks` *`block_designs`*

Specifies the list of child block designs to create abstract view. The parent design will switch to use the abstract view as reference for the instantiations of the corresponding designs, if they are not referencing to abstract view already. This option is mutually exclusive with *-all_blocks*. If no *-blocks* or *-all_blocks* is specified, the abstract view for the current design is created.

In a multi-level physical hierarchy design, only one level of physical hierarchy can be abstract view.

`-all_blocks`

Specifies that abstract view is to be created for all the child blocks in the current design, given that the block is the lowest in the physical hierarchy tree that is allowed to have abstract view. The parent design will switch to use the abstract view as reference for instantiations of the corresponding designs, if they are not referencing to abstract view already. This option is mutually exclusive with

Feedback

-blocks. If the *-blocks* or *-all_blocks* option is not specified, the command creates an abstract view for the current design.

In a multi-level physical hierarchy design, the tool will create abstract for the lowest level of block.

`-force_recreate`

This option only works with *-blocks* or *-all_blocks*. Without *-blocks* and *-all_blocks*, the command will always re-create the abstract view of the current block.

When *-blocks* or *-all_blocks* is specified, the tool would first search the physical hierarchy tree looking for the blocks to create abstract view. After the tool finds a certain block that should create abstract view for, it checks whether the block already has an abstract view and whether this abstract view is of the same type the user wants to create now. By default, the tool would not attempt to re-create the abstract view if the existing one is of the same type.

If the *-force_recreate* option is specified, the tool would do the proper view merge, delete the existing abstract view, and create a new abstract view, even if the existing one is of the correct type. This can be useful when the user wants to make sure that the blocks use the up-to-date abstract views.

`-read_only`

Specifies that the abstract view being created is read-only. By default, when an abstract view is created, the design view of the block is locked and becomes read-only. By specifying this option, you are asking the tool to make the abstract view read-only and keep the editability of the design view.

This option has no effect when *-placement* is specified. The two options are mutually exclusive.

`-include_objects {`*`include_objects_collection`*`}`

Specifies that some objects need to be retained in the abstract. These objects can be ports, leaf pins, hierarchical pins or nets. Specifying a pin (leaf or hierarchical) will cause the cell of the pin to be included in the abstract. Specifying a net *n* will cause the pins on the same flat net as *n* that are also specified in the *include_objects_collection* to be connected in the abstract. At least one leaf-level driver and one leaf-level load on the flat net containing *n* need to be specified for the connection to occur.

This option can be used for both timing and placement abstracts. This option cannot be used together with options *-blocks*, *-all_blocks* and *-estimate_timing*.

Feedback

`-target_use implementation | planning`

Specifies the stage in which the created abstract is targeted to be used. Based on the target stage, tool will apply appropriate internal settings.

You can select one of the two stages:

- *implementation* : The abstract is targeted to be used in top-level implementation.

  Abstract creation is allowed in any level of physical hierarchy.

- *planning* : The abstract is targeted to be used in design planning.

  Abstract creation by default is allowed only on blocks which does not have any descendant block that can be abstract view. This can be overridden by setting the *abstract.allow_all_level_abstract* application option to true.

`-preserve_block_instances true | false`

This option is relevant to designs with nested physical hierarchies. This option determines whether lower levels of physical hierarchies are preserved or whether the hierarchy is made part of the current hierarchy. If this option is set to false, tool will create a flattened abstract. The default value of the option is true.

Description

This command creates an abstract view of the current block. If the block already has an abstract view, this command removes the existing abstract and generates a new abstract view. All leaf cells of the block needs to be mapped prior to abstract creation.

This command also saves the current block to disk.

Abstract view contains all the information that is needed for design planning. For top-level implementation, in addition to abstract, create a frame view using the *create_frame* command.

By default, the abstract view is editable and the design view is locked and becomes read-only. You can open and modify the design view, but *save_block* or *save_lib* would not be able to save the modified design view to disk. If you want to save the modified design view, you have a choice. You can either call *remove_abstract* to remove the abstract view and release the write lock on the design view, or call *create_abstract* to remove the old abstract view, save the modified design view to disk and create a new abstract view.

Design Flow for Abstracts

By default, an editable abstract view is created. At the same time, the design view of the block is locked and becomes read-only.

Feedback

After the abstract view of the block is created, you can change the instantiation of the block in a parent block to reference to the abstract view using the *change_abstract* command.

If the abstract view is editable and instantiated in a parent block, you can make changes to it in the parent block context. Changes in the abstract view are brought back into the full netlist design view through merge. Merge happens automatically when the design view is loaded. You can also call merge explicitly using the command *merge_abstract*.

The merge operation requires that the full netlist design view remain unchanged between the time that the abstract is created with the *create_abstract* command and the abstract is merged back to the design view.

Resuming Editing of the Full Netlist

When an editable abstract view is created. At the same time, the design view of the block is locked and becomes read-only. The read-only design view can still be opened and modified in memory. But if you want to commit the in-memory modifications to disk, you won't be able to do it with *save_block* or *save_lib* command. There are three ways to save the in-memory modification of an abstract-locked design view to disk:

1. You can save it to another design using *save_block -as xxx*.
2. If you no longer need to use the abstract view, you can call *remove_abstract* to delete the abstract view and release the lock on the design view. Then, you will be able to use *save_block* or *save_lib* to save the design view.
3. If you want to get an updated abstract view according to the latest design view in-memory, you can call *create_abstract* command. The *create_abstract* command will delete the existing abstract view, release the lock on the design view, save the design view to disk, create the new abstract view, and lock the design view again if no *-read_only* is specified.

Summary for timing abstract creation

When a timing abstract is created, the tool by default retains

- Data and clock paths needed for analysis and optimization at top-level

  In addition, some cells in the interface logic are retained because they are used in timing constraints or exceptions. The log will contain a summary reporting how many cells were kept because of exceptions. The summary also reports how many pins in

Feedback

the design were affected by each type of exception or constraint. Specifically, the report includes:

- *User size only* : Number of pins on cells that are size only (set by the command set_size_only)
- *Exception* : Number of pins referred to by timing exceptions like set_false_path, set_multicycle_path, set_max_delay etc.
- *Clock* : Number of pins that are a clock source, a generated clock source or a master pin for a generated clock.
- *Clock Gating* : Number of pins that belong to clock gating cells.
- *Constraint* : Number of pins referred to in constraints like set_input_delay, set_output_delay, set_max_time_borrow etc.
- *Case analysis* : Number of pins with case analysis values (defined with set_case_analysis command).
- *Cell mode* : Number of pins that have cell mode constraints (defined with set_cell_mode command).
- *Disable timing* : Number of pins that have disable timing exception (defined using the set_disable_timing command).
- *CTS exception* : Number of pins that have CTS exceptions on them, for example set_clock_balance_points.
- *PVT* : Number of pins that have PVT exceptions, like set_operating_conditions, set_voltage, set_temperature etc.
- *Latency* : Number of pins that have a clock latency set (this affects only pins that are not on sequential cells).
- *Clock sense* : Number of pins that have a set_clock_sense set.

Multi-mode and multi-corner support

During create_abstract, the tool

- identifies and retains the timing level based interface logic across all active modes
- Retains interface logic pins with constraints across all modes (active and inactive)
- Retains parasitics for all corners (active and inactive)

  Ensure that all the scenarios used at top-level are defined and active while creating abstract.

Feedback

Multivoltage support

During create_abstract, the tool

- stores the UPF relevant to the retained interface logic. This is promoted to the top-level during linking.

Multi-level physical hierarchy design

- Creating abstract for using in Design Planning Flow

  In a multi-level physical hierarchy design, only one level of physical hierarchy can be an abstract view. By default, it's the lowest level of blocks.

- Creating abstract for Top-level Place and Route

  Nested abstracts are supported for top-level place and route. Set the abstract.allow_all_level_abstract application option.

Creating abstracts with power annotation

- Set the abstract.annotate_power application option to create abstracts with power information. This enables you to perform power analysis of the complete design while at top-level

Creating abstracts for Signal EM Analysis

- Set the abstract.enable_signal_em_analysis application option to true before running *create_abstract*. This enables you to signal EM analysis inside abstracts while at top-level

Examples

The following example creates an abstract view, with timing information, for the current design.

```
prompt> create_abstract
```

The following example creates an abstract view that is suitable for top-level global placement.

```
prompt> create_abstract -placement
```

The following example creates an abstract view that is suitable for top-level optimization.

```
prompt> create_abstract
```

The following example runs *estimate_timing* on the interface logic of the current design, then creates an abstract view that includes the result of the estimated (virtually optimized) timing.

```
prompt> create_abstract -estimate_timing
```

Feedback

The following example calls *create_abstract* from the top level, finds all the child blocks that are abstract view or can be an abstract view, and create the up-to-date abstract view including merging any changes from existing abstract view to the design view, also change the instantiations in parent blocks to reference to the block's abstract view.

```
prompt> create_abstract -all_blocks -force_recreate
```

In the following example we assume that the design contains a net n1 that connects a driver D1 to loads L1, L2, L3, L4. Using the sequence of commands shown, will ensure that the abstract contains the cells of the pins D1 and L3 and that D1 and L3 are connected by a net in the abstract.

```
prompt> set c_pins [get_pins {D1 L3}]
prompt> set c_nets [get_nets {n1}]
prompt> set cAll [add_to_collection $c_pins $c_nets]
prompt> create_abstract -include_objects $cAl
```

The following example creates a flattened abstract if a block has nested blocks in it. If the block does not have any nested blocks, it simply creates abstract for the block.

```
prompt> create_abstract -preserve_block_instances false
```

Feedback

create_abut_rules

Creates spacing rules or keepout margins for cells in a design.

Syntax

status *create_abut_rules*

```
[-soft_keepout]
[-hard_keepout]
[-keepout_width width]
[-number_of_references number]
[-use_lib]
[-output] filename
```

Data Types

```
width float
number int
filename string
```

Arguments

`-soft_keepout`

Uses soft keepout margins instead of spacing rules.

`-hard_keepout`

Uses hard keepout margins instead of spacing rules.

`-keepout_width width`

Specifies the soft keepout margin width to use, in microns. This option should only be used if the *-soft_keepout* or *-hard_keepout* option is used. The default value is the site width.

`-number_of_references number`

Specifies the number of top pin_density values, from which to obtain references to apply spacing rules or keepout margins. The default is 6.

`-use_lib`

Specifies that library reference cells are used as a source for top pin_density lib cells, instead of reference cells found in the design.

`-output filename`

Specifies the output command filename.

Feedback

Description

The *create_abut_rules* command helps to improve routability of a design by spacing cells further apart with the use of keepout_margins or by flipping cells. Before running this command, run the *check_routes* command to ensure that the DRC error information is up-to-date.

The command *create_abut_rules* creates either spacing rules (default) or soft/hard keepout margins on reference cells with the top six (default) largest pin_density values. These reference cells are found in the design. If the *-use_lib* option is specified, then the libraries are used to derive the reference cells. An output file is written out.

Examples

The following example runs the *create_abut_rules* command using the top 4 pin density values to derive reference cells found in the design to apply spacing rules to.

```
prompt> create_abut_rules -number_of_references 4 -output abut_4.tcl
```

The following example creates a soft keepout margin of width 2 microns using the libraries as reference cells to apply soft keepout margins to.

```
prompt> create_abut_rules -number_of_references 5 -output soft_abut_5.tcl
 \\
   -soft_keepout -keepout_width 2
```

---

create_alignment_marker_cell

Given a 3D-IC design, create appropriate alignment marker cells on the required host dies according to the alignment marker rules.

Syntax

status *create_alignment_marker_cell*

```
[-rules rule_list]
[-host_dies host_die_list]
[-adjacent_dies adjacent_die_list]
```

Feedback

Data Types

rule_list	list
host_die_list	list
adjacent_die_list	list

Arguments

`-rules`

Specify a list of alignment marker rules to create alignment marker cells. By default, all rules within the current block will be considered.

`-host_dies`

Specify the host dies for alignment marker rules to create alignment marker cells. By default, all dies in the current design will be considered.

`-adjacent_dies`

Specify the adjacent dies for the alignment marker rules. By default, all dies in the current design will be considered. For each host die, the command will identify the suitable adjacent dies from the adjacent_die_list to create the cells.

Description

The *create_alignment_marker_cell* command creates new alignment marker cells in the current design. If the created cells exceed the boundary of the host die or overlap with another cell with the same reference, the creation will fail.

Prerequisites

`create_alignment_marker_rule`

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

Assuming the current design includes an interposer, Die1, and Die2, where only Die1 is an adjacent die of the interposer.

When we create an alignment marker rule and the reference object of this rule is host die:

```
prompt> create_alignment_marker_rule -name AMR1 -reference_die HOST
 -type CORNER -reference_object DIE_BOUNDARY -x_offset 500 -y_offset 800
 -lib_cell AM_L -reference_corner bottom_left
```

The following examples will create the same alignment marker cell on the interposer.

```
prompt> create_alignment_marker_cell -rules {AMR1} -host_dies
 {interposer}
```

Feedback

```
prompt> create_alignment_marker_cell -host_dies {interposer}
```

When we create an alignment marker rule and the reference object of this rule is adjacent die:

```
prompt> create_alignment_marker_rule -name AMR2 -reference_die ADJACENT
 -type CORNER -reference_object DIE_BOUNDARY -x_offset 500 -y_offset 800
 -lib_cell AM_L -reference_corner bottom_left
```

The following examples will create the same alignment marker cell on interposer reference to the adjacent die.

```
prompt> create_alignment_marker_cell -rules {AMR2}

prompt> create_alignment_marker_cell -rules {AMR2} -host_dies
 {interposer}

prompt> create_alignment_marker_cell -rules {AMR2} -host_dies
 {interposer} -adjacent_dies {Die1}

prompt> create_alignment_marker_cell -rules {AMR2} -host_dies
 {interposer} -adjacent_dies {Die1 Die2}

prompt> create_alignment_marker_cell -rules {AMR2} -adjacent_dies {Die1}

prompt> create_alignment_marker_cell -rules {AMR2} -adjacent_dies {Die1
 Die2}
```

corner_n_lib_cell_pair_list              list
```

Arguments

`-name rule_name`

Specifies the name of the alignment marker rule to be created. Empty rule name and already used name cannot be provided.

Feedback

`-type` *`rule_type`*

Specifies the type of the alignment marker rule to be created. Rule type enumeration values can be one of from none, step, corner, projection, blockage, inside_symmetry or outside_symmetry. Default rule type is none.

`-design` *`design`*

Specifies the design in which to create the alignment marker rule. If no design is specified, the alignment marker rule is created in the current design. This is an optional option.

`-lib_cell` *`lib_cell`*

Specifies lib_cell designs. The lib_cell library should be reference library of alignment_marker_rule design's library or its reference libraries. Only one lib_cell design is allowed for rule_type none, step, corner, projection, inside_symmetry or outside_symmetry. More than one lib_cell design can be provided with rule_type blockage.

`-reference_die` *`reference_die`*

The reference chiplet object to define the alignment marker location. Die type enumeration values can be one of from host, adjacent, or projection. Default value for this option is host. This option must be provided when creating rule of type default or step or corner.

`-projection_map` *`ref_marker_n_host_marker_pair_list`*

Specifies list of pair of reference_marker and host_marker strings. This option must be provided only when creating rule of type "projection". Command options -lib_cell, reference_object, -reference_object_name, -reference_layer, -reference_corner, -orientation, -x_offset, -y_offset, -x_step, -y_step, -x_num, -y_num, -reference_die_orientation, -quadrant, -x_spacing, -y_spacing, -x_enclosure, and -y_enclosure are mutually exclusive with -projection_map.

`-reference_object` *`object_enum`*

Specifies reference shape object in reference chiplet to define the alignment marker location. Reference object enumeration values can be any of from die_boundary, seal_ring, scribe_line, stitching_zone, layer_shape or custom. Default value for this option is die_boundary.

`-reference_object_name` *`object_name`*

Optionally specifies reference object name for alignment marker rule.

`-reference_layer` *`layer`*

Optionally specifies reference layer for reference object shape type layer. This option must be provided if -reference_object is of type layer_shape only.

Feedback

`-reference_corner` *`reference_corner`*

Specifies reference corner of the reference shape. It's value can be any one from top_left, top_right, bottom_left or bottom_right. Default value for this option is bottom_left. This option is mandatory when creating rule of type step or corner.

`-orientation` *`orientation`*

Specifies orientation of the alignment marker cell. It's values can be any one from R0, R90, R180, R270, MX, MXR90, MY, or MYR90. Default value for this option is R0. This option is mandatory when creating rule of type step or corner.

`-x_offset` *`distance_pair_list`*

Specifies preshrink horizontal offset from ref_corner to lower left corner of alignment marker cell placement after orient. This option can be provided only when creating rule of type step or corner. This option is mutually exclusive with *-quadrant*, *-x_spacing*, *-y_spacing*, *-x_enclosure*, and *-y_enclosure* options. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-y_offset` *`distance_pair_list`*

Specifies preshrink vertical from ref_corner to lower left corner of alignment marker cell placement after orient. This option can be provided only when creating rule of type step or corner. This option is mutually exclusive with *-quadrant*, *-x_spacing*, *-y_spacing*, *-x_enclosure*, and *-y_enclosure* options. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-x_step` *`dist_value`*

Optionally specifies preshrink x step value. Default value for this option is 0. This option can be provided only when creating step rule.

`-y_step` *`dist_value`*

Optionally specifies preshrink y step value. Default value for this option is 0. This option can be provided only when creating step rule.

`-x_num` *`value`*

Optionally specifies preshrink x num value. Default value for this option is 0. This option can be provided only when creating step rule.

`-y_num` *`value`*

Optionally specifies preshrink y num value. Default value for this option is 0. This option can be provided only when creating step rule.

Feedback

`-reference_die_orientation` *`orientation`*

Specifies the reference die's orientation. Its values can be any one from R0, R90, R180, R270, MX, MXR90, MY, or MYR90. Default value for this option is invalid. This option must be specified with *-reference_die* option.

`-quadrant` *`quadrant`*

Specifies the quadrant with respect to the die corner where the alignment marker cell will be placed. Quadrant enumeration values can be any of from top_left, top_right, bottom_left or bottom_right. This option must be specified with *-x_spacing* and *-y_spacing* options if rule type is not *outside_symmetry*. This option is mutually exclusive with *-x_offset*, *-y_offset*, *-x_enclosure*, and *-y_enclosure* options.

`-x_spacing` *`distance_pair_list`*

Specifies the horizontal distance from alignment marker cell boundary to alignment marker cell boundary to vertical edge of reference die boundary in pre-blow up die dimension. This option must be specified with *-quadrant* option. This option is mandatory for rule type *outside_symmetry*. This option is mutually exclusive with *-x_offset*, *-y_offset*, *-x_enclosure*, and *-y_enclosure* options. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-y_spacing` *`distance_pair_list`*

Specifies the vertical distance from alignment marker cell boundary to alignment marker cell boundary to horizontal edge of reference die boundary in pre-blow up die dimension. This option must be specified with *-quadrant* option. This option is mandatory for rule type *outside_symmetry*. This option is mutually exclusive with *-x_offset*, *-y_offset*, *-x_enclosure*, and *-y_enclosure* options. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-x_enclosure` *`distance_pair_list`*

Specifies the horizontal distance from alignment marker cell boundary to the vertical edge of reference die across reference corner in pre-blow up die dimension. This option is mandatory for rule type *inside_symmetry*. This option is mutually exclusive with *-x_offset*, *-y_offset*, *-quadrant*, *-x_spacing*,and *-y_spacing* options. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-y_enclosure` *`distance_pair_list`*

Specifies the vertical distance from alignment marker cell boundary to the horizontal edge of reference die across reference corner in pre-blow up die dimension. This option is mandatory for rule type *inside_symmetry*. This option is mutually exclusive with *-x_offset*, *-y_offset*, *-quadrant*, *-x_spacing*,and

Feedback

-y_spacing options. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition.

`-reference_cells` *`lib_cell_list`*

Specifies the reference cells whose instances are considered for rule of type blockage. The keepout will be applied around these instances depending on the margin attribute of the rule. The reference cells library should be reference library of alignment_marker_rule design's library or its reference libraries. This option can be provided only when creating rule of type *blockage*.

`-boundary` *`geometry`*

Specifies the list of points which represent the blockage area. This will create a placement blockage of type alignment marker. The blockage boundary should not exceed the block's boundary. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  `{{llx lly} {urx ury}}`

- Specify a rectilinear boundary by using the following syntax to specify the boundary of the polygon:

  `{{x1 y1} {x2 y2} ... {xn yn}}`

  This option can be provided only when creating rule of type *blockage* and mutually exclusive with *-reference_cells* or *-margin*.

`-target_object` *`object_enum`*

Specifies the shape object in target chiplet to define the alignment marker location. Object enumeration values can be any of from die_boundary, seal_ring, scribe_line, stitching_zone, layer_shape or custom. This option can be provided only when creating rule of type *projection*. This option must be specified with *-target_x_enclosure* and *-target_y_enclosure* options.

`-target_x_enclosure` *`distance_pair_list`*

Specifies the horizontal distance from alignment marker boundary to the vertical edge of target die across reference corner in pre-blow up die dimension. This option can be provided only when creating rule of type *projection*. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition. This option must be specified with *-target_object* and *-target_y_enclosure* options.

Feedback

`-target_y_enclosure` *`distance_pair_list`*

Specifies the vertical distance from alignment marker boundary to the horizontal edge of target die across reference corner in pre-blow up die dimension. This option can be provided only when creating rule of type *projection*. Only non-negative float values are allowed for this option. Please refer to *DESCRIPTION* section for distance_pair_list definition. This option must be specified with *-target_object* and *-target_x_enclosure* options.

`-target_object_name` *`object_name`*

Specifies target object name for alignment marker rule. This option must be provided if target_object is of type *custom* only. This option can be provided only when creating rule of type *projection*.

`-target_layer` *`layer`*

Specifies target layer for target object shape type layer. This option must be provided if target_object is of type layer_shape only. This option can be provided only when creating rule of type *projection*.

`-orientation_map` *`corner_n_orient_pair_list`*

Specifies the orientations of the alignment marker cells used at each corner of the die. This option can be provided only when creating rule of type *projection*. The corner_n_orient_pair_list will be list of pairs containing pair whose first element is corner_type (valid values : top_left, top_right, bottom_left or bottom_right) and second element is orientation (valid values : R0, R90, R180, R270, MX, MXR90, MY, or MYR90). Size of corner_n_orient_pair_list must be either 2 or 4. The size of *orientation_map* should be equal to size of *lib_cell_map*. If the size of map is 2 opposite corners should be specified i.e. *bottom_left* with *top_right* or *bottom_right* with *top_left*. Specified corners of *orientation_map* should be match the specified corners of *lib_cell_map*.

`-lib_cell_map` *`corner_n_lib_cell_pair_list`*

Specifies the list of lib_cells of alignment marker cells used at each corner of the die. This option can be provided only when creating rule of type *projection*. The corner_n_lib_cell_pair_list will be list of pairs containing pair whose first element is corner_type (valid values : top_left, top_right, bottom_left or bottom_right) and second element is a valid lib_cell name. Size of corner_n_lib_cell_pair_list must be either 2 or 4. The size of *orientation_map* should be equal to size of *lib_cell_map*. Specified corners of *lib_cell_map* should be match the specified corners of *orientation_map*.

`-margin` *`margin_spec`*

Specifies the padding margin to maintain outside of the design boundary i.e. reference cells. This setting is used for physical designs. This option can be provided only when creating rule of type *blockage* and can be provided only

Feedback

with *-reference_cells*. This will create keepout margin of type alignment marker around the reference cells.

Description

This command creates a new alignment_marker_rule with the given name based on the options specified, and returns the created object. This rule can be used to create and place alignment marker cells or to check the validity of the design with additional information provided by the user such as the die, bounding region, and cell naming conventions.

The *distance_pair_list* can either be a single float value or a list of float pairs.

A single value of *x_offset* can be specified as follows: *-x_offset distance_value*, which means that x_offset must be exactly equal to that value.

Ranges of values can be specified via a list of float pairs using standard interval notation. For example , { (a b) [c d] [e f) (g h] } means that valid values of the command option are: a < x < b, c <= x <= d, e <= x < f, and g < x <= h. In other words, any value that falls within these ranges is valid. In the ranges, minimum value should be less than or equal to maximum values. And two ranges should not intersect each other.

Examples

The following example creates an alignment marker rule object of step type.

```
prompt> create_alignment_marker_rule -name AMR1 \\
                                          -type step -reference_die
 ADJACENT \\
                                          -reference_object DIE_BOUNDARY \\
                                          -x_num 4 -y_num 6 -x_step 30
 -y_step 40 \\
                                          -x_offset { [10 20] (30 40]}
 -y_offset 20 \\
                                          -lib_cell tcbn90glvt/AN2LVTD0 \\
                                          -orientation R0 -reference_corner
 top_left
```

The following rule creates an alignment marker rule object with reference_object of type projection.

```
prompt>  create_alignment_marker_rule -name AMR2 \\
                                           -type projection -reference_die
 PROJECTION \\
                                           -projection_map {{"ref1"
 "host1"} {"ref2" "host2"}}
```

The following rule creates an alignment marker rule object with reference_object of type layer_shape.

Feedback

```
prompt>  create_alignment_marker_rule -name AMR3 \\
                -reference_die ADJACENT \\
                -reference_object LAYER_SHAPE \\
                -x_num 4 -y_num 6 -x_step 30 -y_step 40 \\
                -x_offset 10 -y_offset 20 \\
                -lib_cell tcbn90glvt/AN2LVTD0 \\
                -orientation R0 -reference_corner top_left \\
                -reference_layer M2
```

The following example creates an alignment marker rule object of default type and reference_object of type custom.

```
prompt> create_alignment_marker_rule -name AMR4 \\
                                        -type none -reference_die
 ADJACENT \\
                                        -reference_object custom \\
                                        -reference_object_name STZONE \\
                                        -x_num 4 -y_num 6 -x_step 30
 -y_step 40 \\
                                        -x_offset 10 -y_offset 20 \\
                                        -lib_cell tcbn90glvt/AN2LVTD0 \\
                                        -orientation R0 -reference_corner
 top_left
```

The following example creates an alignment marker rule object of corner type, quadrant, x_spacing and y_spacing in specified design 'design1'.

```
prompt> create_alignment_marker_rule -name AMR_spacing -type corner \\
                      -design design1 \\
                      -reference_die HOST -lib_cell libCell
 -reference_object CUSTOM \\
                      -reference_corner bottom_left -orientation R0 \\
                      -reference_die_orientation R0 -quadrant top_right
 \\
                      -x_spacing {(12 24) [ 36 480e-1 ]  [6e+1 72) ( 78
 82] } \\
                      -y_spacing { [98 98] [84 96] }
```

The following example creates an alignment marker rule object of blockage type. This will also create the placement blockage of type alignment marker.

```
prompt> create_alignment_marker_rule -name AMR_blockage -type blockage \\
                      -boundary {{0 0} {100 200} {200 100}} \\
                      -lib_cell {libCell1 libCell2}
```

The following example creates an alignment marker rule object of blockage type. This will also create the keepout margin of type alignment marker around reference cells.

```
prompt> create_alignment_marker_rule -name AMR_blockage -type blockage \\
                      -margin {1 2 1 2} \\
```

Feedback

```
                    -reference_cells {libCell1 libCell2} \\
                    -lib_cell {libCell3 libCell4}
```

The following example creates an alignment marker rule object of projection type, target_object, target_layer, target_x_enclosure and target_y_enclosure.

```
prompt> create_alignment_marker_rule -name AMR_target -type projection \\
                    -target_object layer_shape -target_layer M1
 -target_x_enclosure { [1 3] } -target_y_enclosure 9 \\
                    -projection_map {{"libCell3" "libCell4"}}
```

The following example creates an alignment marker rule object of outside_symmetry type, lib_cell_map, and orientation_map.

```
prompt> create_alignment_marker_rule -name AMR_outside -type
 outside_symmetry -reference_die HOST \\
                    -reference_object DIE_BOUNDARY -x_spacing 10
 -y_spacing 20 \\
                    -lib_cell_map { {top_left libCell5} {bottom_right
 libCell6} } \\
                    -orientation_map { {top_left R90} {bottom_right
 R270} }
```

---

create_always_statement

Creates 1 RTL always statement.

Syntax

collection *create_always_statement*

```
rtl_statement
-sensitivity_list sensitivity_list
[-name name]
[-type type]
[-module module | -cell cell]
[-scope scope]
```

Data Types

```
rtl_statement       collection
sensitivity_list    collection
name                string
```

Feedback

type	string
module	collection
cell	collection
scope	collection

Arguments

`rtl_statement`

Specifies only 1 RTL statement used for the always statement. This can be a begin statement, which contains various statements. This is a required argument. The following RTL statements are supported:

- rtl_assignment • rtl_begin_end • rtl_case • rtl_for • rtl_foreach • rtl_if_else • rtl_repeat • rtl_package • rtl_parameter • rtl_variable • rtl_expression • rtl_while

`-sensitivity_list` *sensitivity_list*

Specifies the RTL statement of type expression used for the always statement.

`-name` *name*

Specifies the name used for the always statement.

`-type` *type*

Specifies the type of the always block. The default type is standard. The available values are standard, flip-flop, latch, or combinational.

`-module` *module*

Specifies the module to create the always statement in. This option is mutually exclusive with the *-cell* option.

`-cell` *cell*

Specifies the cell to create the always statement in. This option is mutually exclusive with the *-module* option.

`-scope` *scope*

Adds the newly created always statement in the scope provided by the RTL statement.

Description

This command creates an RTL always statement. The always statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the always statement is created in the current instance.

Feedback

Examples

The following example creates 1 always statement in the current instance with the begin end statement named *one* and sensitivity list named *two*.

```
prompt > create_always_statement [get_statements -filter "type ==
 begin_end" one] \\
   -sensitivity_list [get_statements -filter "type == expression" two] \\
   {"RTL_ALWAYS_1"}
```

The following example creates 1 always statement named *two_always* in the current instance with the begin end statement named *one* and sensitivity list named *two*.

```
prompt > create_always_statement [get_statements -filter "type ==
 begin_end" one] \\
   -name two_always -sensitivity_list [get_statements -filter "type ==
 expression" two] \\
   {"two_always"}
```

- remove_statements

---

create_anchor

Creates an anchor in the current block.

Syntax

collection *create_anchor*

```
-dependent_object object
[-name name]
[-type location | location_x_y]
[-anchor_object object]
[-anchor_x_object object]
[-anchor_y_object object]
[-dependent_object_position center | bbox_center | bbox_ll | bbox_ul |
 bbox_ur | bbox_lr]
[-anchor_object_position center | bbox_center | bbox_ll | bbox_ul |
 bbox_ur | bbox_lr]
[-anchor_x_object_position center | bbox_center | bbox_ll | bbox_ul |
 bbox_ur | bbox_lr]
[-anchor_y_object_position center | bbox_center | bbox_ll | bbox_ul |
 bbox_ur | bbox_lr]
[-offset distance_list]
[-anchor_orientation]
```

Feedback

Data Types

object	collection
name	string
distance_list	float

Arguments

`-dependent_object` *object*

Specifies the dependent (anchored) object. The object must be in the same block as the anchor being created. Note that if the dependent object gets subsequently removed, this anchor also be automatically removed.

An object might be the dependent object of no more than one anchor. It is an error to specify an object that is already the dependent object of an existing anchor. Also, the dependent object might not belong to an edit group.

This is a required argument.

`-name` *name*

Specifies the name of the anchor. If unspecified, the command generates a name automatically using the prefix "ANCHOR" with a system-generated number appended.

`-type location | location_x_y`

Specifies the type of the anchor. If type is "location", then the dependent_object's location is anchored to a single object, specified by the *-anchor_object* argument. If type is "location_x_y", then the dependent_object is anchored to two objects, specified by the *-anchor_x_object* and *-anchor_y_object* arguments. If unspecified, the type defaults to "location".

`-anchor_object` *object*

Specifies the anchor object, to which the dependent object specified by the *-dependent_object* argument is anchored. This argument might only be specified if the anchor type is "location".

When the anchor object is set, the dependent (anchored) object's location is shifted (translated)such that the points defined by the *-dependent_object_position* option on the dependent object and *-anchor_object_position* option on the anchor object are separated by the distance specified by the *-offset* attribute. As the location of the anchor object changes, so does the dependent object's location to maintain the specified offset.

If the *-offset* argument is not specified, then the offset is automatically computed based on the current locations of the dependent and anchor objects, such that the dependent object is not be shifted by this command.

Feedback

The value of this argument must be a collection of a single object. Many object classes that have physical extent, such as cells, shapes, vias, terminals, voltage_areas, edit_groups, and so on might be specified as the anchor object.

`-anchor_x_object` *`object`*

Specifies the anchor x object, to which the x-coordinate of the dependent object specified by the *-dependent_object* argument is anchored. This argument might only be specified if the anchor type is *location_x_y*.

When the anchor x object is set, the dependent (anchored) object's location's x-coordinate is adjusted such that the points defined by *-dependent_object_position* on the dependent object and *-anchor_x_object_position* on the anchor x object are separated by the distance specified by the x component of the *-offset* attribute. As the location of the anchor x object changes, so does the dependent object's x-coordinate to maintain the specified offset.

If the *-offset* argument is not specified, then the offset is automatically computed based on the current locations of the dependent and anchor objects, such that the dependent object is not be shifted by this command.

The value of this argument must be a collection of a single object. Many object classes that have physical extent, such as cells, shapes, vias, terminals, voltage_areas, edit_groups, and so on might be specified as the anchor x object.

`-anchor_y_object` *`object`*

Specifies the anchor y object, to which the y-coordinate of the dependent object specified by the *-dependent_object* argument is anchored. This argument might only be specified if the anchor type is *location_x_y*.

When the anchor y object is set, the dependent (anchored) object's location's y-coordinate is adjusted such that the points defined by *-dependent_object_position* on the dependent object and *-anchor_y_object_position* on the anchor y object are separated by the distance specified by the y component of the *-offset* attribute. As the location of the anchor y object changes, so does the dependent object's y-coordinate to maintain the specified offset.

If the *-offset* argument is not specified, then the offset is automatically computed based on the current locations of the dependent and anchor objects, such that the dependent object is not be shifted by this command.

The value of this argument must be a collection of a single object. Many object classes that have physical extent, such as cells, shapes, vias, terminals, voltage_areas, edit_groups, and so on might be specified as the anchor y object.

Feedback

`-dependent_object_position center | bbox_center | bbox_ll | bbox_ul | bbox_ur | bbox_lr`

Specifies a reference point with respect to the dependent (anchored) object's unrotated geometric shape. This reference point is used as the destination point of the *-offset* between the dependent object and the anchor objects. That is, this reference point is constrained to always equal the reference point defined by the *-anchor_object_position* attribute when the anchor type is *location*, or by the *-anchor_x_object_position* and *anchor_y_object_position* attributes when the anchor type is *location_x_y*, offset by the anchor's *-offset* attribute value. The tool moves the dependent object to meet this constraint when necessary.

The reference point is selected as follows according to the option value, where the "shape" is the unrotated geometric shape of the dependent (anchored) object:

Position Table:

```
"center":      The center of the largest rectangle contained
 within the
               unrotated object shape,
"bbox_center": The center of the unrotated shape's bounding box,
"bbox_ll":     The lower-left corner of the unrotated shape's
 bounding box,
"bbox_ul":     The upper-left corner of the unrotated shape's
 bounding box,
"bbox_ur":     The upper-right corner of the unrotated shape's
 bounding box,
"bbox_lr":     The lower-right corner of the unrotated shape's
 bounding box.
```

If unspecified, the default is *center*. The above positions are on the unrotated shapes, such that if the position is "bbox_ll" for example, and the object has orientation R90, then the position point appear s at the lower-right of the object's (rotated) bounding box.

Note:: For cells, if the cell's boundary is set, then the boundary is used in lieu of the bounding box when computing the reference point.

`-anchor_object_position center | bbox_center | bbox_ll | bbox_ul | bbox_ur | bbox_lr`

Specifies a reference point with respect to the anchor object's unrotated geometric shape. This reference point is used as the sourcepoint of the *-offset* between the dependent (anchored) object and the anchor object. That is, the reference point defined by *-dependent_object_position* is constrained to always equal this reference point offset by the anchor's *-offset* attribute value. The tool moves the dependent object to meet this constraint when necessary.

Feedback

The reference point is selected according to the *Position Table* described in the *-dependent_object_position* argument description, where the "shape" is the geometric shape of the anchor object.

If unspecified, the default is *center*. This argument might only be specified if the anchor type is location.

`-anchor_x_object_position center| bbox_center| bbox_ll| bbox_ul | bbox_ur | bbox_lr`

Specifies a reference point with respect to the anchor x object's unrotated geometric shape. This reference point's x-coordinate is used as the source x-coordinate of the *-offset* between the dependent (anchored) object's x-coordinate and the anchor x object. That is, the x-coordinate of the reference point defined by *-dependent_object_position* is constrained to always equal this reference x-coordinate offset by the anchor's *-offset* attribute value's x component. The tool moves the dependent object to meet this constraint when necessary.

The reference point is selected according to the *Position Table* described in the *-dependent_object_position* argument description, where the "shape" is the geometric shape of the anchor x object.

If unspecified, the default is *center*. This argument might only be specified if the anchor type is location_x_y.

`-anchor_y_object_position center| bbox_center| bbox_ll | bbox_ul | bbox_ur | bbox_lr`

Specifies a reference point with respect to the anchor y object's unrotated geometric shape. This reference point's y-coordinate is used as the source y-coordinate of the *-offset* between the dependent (anchored) object's y-coordinate and the anchor y object. That is, the y-coordinate of the reference point defined by *-dependent_object_position* is constrained to always equal this reference y-coordinate offset by the anchor's *-offset* attribute value's y component. The tool moves the dependent object to meet this constraint when necessary.

The reference point is selected according to the *Position Table* described in the *-dependent_object_position* argument description, where the "shape" is the geometric shape of the anchor y object.

If unspecified, the default is *center*. This argument might only be specified if the anchor type is location_x_y.

`-offset` *`distance_list`*

Specifies the offset to be maintained between the reference points defined by the *-dependent_object_position* and the *-anchor_object_position* attribute values when the anchor type is location, or the *-dependent_object_position*,

Feedback

-anchor_x_object_position, and *-anchor_y_object_position* attribute values when the anchor type is location_x_y. See the descriptions of the *-dependent_object_position*, *-anchor_object_position*, *-anchor_x_object_position*, and *-anchor_x_object_position* arguments for a description of how these reference points are computed. The offset between the reference points is constrained to be the value of this option. The tool moves the dependent object to meet this constraint when necessary.

If unspecified, the default is "{0 0}" (no offset).

`-anchor_orientation`

Specifies whether to also lock the dependent object's relative orientation to that of the anchor object when the anchor type is location, or to the anchor x object when the anchor type is location_x_y. That is, the dependent object keeps its current orientation when this command completes, but rotates by the same amount the anchor object subsequently rotates.

This argument has no effect unless the dependent object's object class has a settable "orientation" attribute.

When unspecified, there is no orientation locking of the dependent object.

Description

The *create_anchor* command creates a new anchor, an object that constrains one physical object's location to the location of another physical object. The object with the constrained location is referred to as the "dependent" or "anchored" object. The object that constrains the dependent object's location is called the "anchor object". Note that "anchor object" is distinct from the object created by this command, which has the object_class "anchor". The use case of an anchor is when you want to lock one object's location to that of another object, and have that object automatically be moved by the tool whenever the other object is moved.

Anchor has two types: "location" and "location_x_y". When type is location, anchor constrains a dependent object's location to a single anchor object as described previously. When type is "location_x_y", anchor constrains a dependent object to two different anchor objects, where one anchor object's x-coordinate constrains the dependent object's x-coordinate, and the other anchor object's y-coordinate constrains the dependent object's y-coordinate.

Whereas the dependent object must be in the same block as the anchor, the anchor object might be either in the same block or in a lower level of physical hierarchy.

Anchor must always have a dependent object, and if the dependent object is removed, then the anchor is also removed automatically. A dependent object might also be the anchor object of another anchor, forming chains of anchorage, however dependency cycles result in an error. An object might only be a dependent object of one anchor at a time, and might not be a member of an edit group.

Feedback

Examples

The following example anchors cell A to cell B:

```
prompt> create_anchor -dependent_object [get_cells A] -anchor_object
 [get_cells B]
{ANCHOR0}
```

The following example anchors cell A to the lower-left of edit_group mid/EG0:

```
prompt> create_anchor -dependent_object [get_cells A] \\
   -anchor_object [get_edit_groups mid/EG0] -anchor_object_position
 bbox_ll
{ANCHOR0}
```

The following example anchors the lower-left of voltage_area VA0's bounding box to the upper-right of cell mid/B's bounding box:

```
prompt> create_anchor -dependent_object [get_voltage_areas VA0] \\
   -dependent_object_position bbox_ll -anchor_object [get_cells mid/B] \\
   -anchor_object_position bbox_ur
{ANCHOR0}
```

The following example anchors the lower-left of cell A's bounding box to be 4 microns to the left of the upper-right of cell mid/B's bounding box:

```
prompt> create_anchor -dependent_object [get_cells A] \\
   -dependent_object_position bbox_ll -anchor_object [get_cells mid/B] \\
   -anchor_object_position bbox_ur -offset {-4 0}
{ANCHOR0}
```

The following example anchors bump_region BR0 to be 3 microns to right of cell B's center horizontally, and 4 microns above terminal TM_0's center vertically:

```
prompt> create_anchor -type location_x_y \\
   -dependent_object [get_bump_regions BR0] -anchor_x_object [get_cells
 B] \\
   -anchor_y_object [get_terminals TM_0] -offset {3 4}
{ANCHOR0}
```

create_annotation_shape

Creates an annotation_shape object of shape types circle, line, polygon, and rect in the current design.

Feedback

Syntax

```
collection create_annotation_shape
-type circle | line | polygon | rect
-annotation_points annotation_points
[-name annotation_name]
[-category  category_name]
[-width  width]
[-start_endcap endcap_type]
[-end_endcap endcap_type]
[-line_arrow]
[-color color]
[-fill fill]
[-pen_style pen_style]
[-pen_width pen_width]
[-label label]
[-horizontal_alignment left | center | right]
[-vertical_alignment bottom | middle | top]
[-orientation orientation]
[-bold_text]
[-elide_text left | middle | right]
[-wrap_text]
[-design design]
```

Data Types

```
annotation_points  list of location descriptors
annotation_name    string
category_name      string
width              float
endcap_type        string
color              string
fill               string
pen_style          string
pen_width          string
label              string
orientation        string
design             string
```

Arguments

`-type circle | line | polygon | rect`

Specifies the type of annotation shape to create.

This is a required option.

Feedback

`-annotation_points` *annotation_points*

Specifies the points for the specified annotation type. The points are specified by a tool command language (Tcl) list in which each list element is one of the following:

- {<coord_x> <coord_y>} a fixed, absolute {x y} point
- {<anchor_collection>} a point that follows an anchor object
- {<anchor_collection> <position> <offset_x> <offset_y>} a point that follows an anchor object at the specified position and offset
- {<offset_x><+/-> <offset_y><+/->} a point that follows the location of the previous point in the list, at the specified offset

The first format describes a simple fixed point at an absolute coordinate.

The second format specifies that the point follow the center of the anchor object, where "center" is the center of the largest box that can be contained within the anchor object's boundary.

The third format specifies that the point follow the anchor object at the specified offset w.r.t. the specified position. The offset x & y values can either be absolute distances or percentage values (which are appended with '%'). The valid position values are as follows:

- center: The center of the largest box within the anchor object
- bbox_center: The center of the bbox of the anchor object
- bbox_ll: The lower-left corner of the bbox of the anchor object
- bbox_ul: The upper-left corner of the bbox of the anchor object
- bbox_lr: The lower-right corner of the bbox of the anchor object
- bbox_ur: The upper-left corner of the bbox of the anchor object

The fourth format is a relative positioning feature that specifies the point follow the previous point at the specified offset, where '+' is appended to the offset to specify a positive relative offset, and '-' is appended to specify a negative relative offset. This relative positioning feature is not available to the first point in the annotation_points list, but is available to any remaining point in the list.

This is a required option.

`-name` *annotation_name*

Specifies the name of the annotation_shape. The name may not contain the special character '/'. If unspecified, the command will generate a name

Feedback

automatically using the prefix "ANNOTATION_SHAPE" with a system-generated number appended.

`-category` *`category_name`*

Specifies the name of the category the annotation_shape object. The category maybe used for grouping of annotation shapes into separate sets. If unspecified, the category will not be assigned for the annotation_shape.

`-width` *`width`*

Specifies the width of line annotation shape. The value must be non-negative.

If you use this option with other annotation shape types, the tool issues an error.

`-start_endcap` *`endcap_type`*

Specifies the type of the start endcap of a line annotation shape.

The valid values are

- *flush* (the default)

  Creates an endcap with square ends and no extension.

- *full_width*

  Creates an endcap with square ends that is extended by the path width.

- *half_width*

  Creates an endcap with square ends that is extended by half the path width.

- *octagon*

  Creates an endcap with octagonal ends.

- *round*

  Creates an endcap with round ends.

  This option is valid only for line annotation shapes; the tool issues an error if you use it for other shape types.

`-end_endcap` *`endcap`*

Specifies the type of the end endcap of a line annotation shape.

The valid values are

- *flush* (the default)

  Creates an endcap with square ends and no extension.

- *full_width*

Feedback

Creates an endcap with square ends that is extended by the path width.

- *half_width*

  Creates an endcap with square ends that is extended by half the path width.

- *octagon*

  Creates an endcap with octagonal ends.

- *round*

  Creates an endcap with round ends.

  This option is valid only for line annotation shapes; the tool issues an error if you use it for other shape types.

`-line_arrow`

Specifies if to show arrow for annotation_shapes of type line.

`-color` *color*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes may be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette. The default color is white.

`-fill` *pattern*

Specifies the annotation fill pattern. The supported values for this option are: BDiagPattern, CrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, DiagCrossPattern, FDiagPattern, HorPattern, NoBrush, SolidPattern, VerPattern. The default fill pattern is NoBrush.

`-pen_style` *pen_style*

Specifies the pen style. The supported values for this option are: CustomDashLine, DashDotDotLine, DashDotLine, DashLine, DotLine, NoPen, SolidLine, The default pen style is SolidLine.

`-pen_width` *pen_width*

Specifies the pen width. The default pen width is 1.

Feedback

`-label` *label*

Specifies the label text.

`-horizontal_alignment left | center | right`

Specifies the horizonal alignment of the label text inside bounding box of annotation shape. This option is not applicable for annotation_shapes of type line. The default value is center.

`-vertical_alignment bottom | middle | top`

Specifies the vertical alignment of the label text inside bounding box of annotation shape. This option is not applicable for annotation_shapes of type line. The default value is middle.

`-orientation` *orientation*

Specifies the orientation of a text label.

Valid values are

- *MX* (mirror around the X-axis)
- *MXR90* (mirror around the X-axis and rotate 90 degrees)
- *MY* (mirror around the Y-axis)
- *MYR90* (mirror around the Y-axis and rotate 90 degrees)
- *R0* (no rotation, which is the default)
- *R90* (rotate 90 degrees)
- *R180* (rotate 180 degrees)
- *R270* (rotate 270 degrees)

`-bold_text`

Specifies to use bold text for the label.

`-elide_text left | middle | right`

Specifies how to elide text with an ellipsis if the text string is too long. If this option is omitted then text is truncated.

This option is mutually exclusive with the *-wrap_text* option.

`-wrap_text`

Specifies to wrap long text lines for the label. If this option is omitted then text is truncated.

This option is mutually exclusive with the *-elide_text* option.

Feedback

`-design` *design*

Specifies the design in which to create the annotation_shapes. If no design is specified, the annotation_shapes are created in the current design.

Description

This command creates a new circle, line, polygon, or rect annotaion_shape and returns a collection that contains the new annotation_shape.

Examples

The following example creates a green annotation_shape of type rect.

```
prompt> create_annotation_shape -type rect -color green \\
   -annotation_points {{200 200} {777 777}}
```

The following example creates a red annotation_shape of type line with width 2.

```
prompt> create_annotation_shape -type line -color red -pen_width 2 \\
   -annotation_points {{123 456} {789 12} {200 200}}
```

The following example creates an orange annotation_shape of type polygon and the text label Anno1.

```
prompt> create_annotation_shape -type polygon \\
   -annotation_points {{800 700} {850 700} {900 650} {900 600} {800 600}}
 \\
   -color orange -label "Anno1"
```

The following example creates a white annotation_shape of type circle with center in the middle of cell 'I_CLOCK_GEN/I_PLL_PC' and radius 50.

```
prompt> create_annotation_shape -type circle \\
   -annotation_points [list [get_cells I_CLOCK_GEN/I_PLL_PCI] {50+ 0+}]
```

Feedback

create_annotation_symbol

Creates an annotation_shape object of type symbol or fit_symbol in the current design.

Syntax

```
collection create_annotation_symbol
-type custom | diamond | square | triangle | x
-origin annotation_point
[-name annotation_name]
[-category category_name]
[-fit_symbol]
[-width width]
[-height height]
[-size size]
[-color color]
[-fill fill]
[-pen_style pen_style]
[-pen_width pen_width]
[-orientation orientation]
[-file file_path]
[-design design]
```

Data Types

```
annotation_point   location descriptor
annotation_name    string
category_name      string
width              float
height              float
size               integer
color              string
fill               string
pen_style          string
pen_width          integer
orientation        string
file_path          string
design             string
```

Arguments

`-type custom | diamond | square | triangle | x`

Specifies the type of annotation_shape of symbol. There are four built-in symbols: diamond, square, triangle, and x (cross). For the custom symbol, specify the input file in SVG format by using the -file option.

This is a required option.

Feedback

`-origin` *`annotation_point`*

Specifies the annotation text origin point. The point is specified by a tool command language (Tcl) list of the following format:

- {<coord_x> <coord_y>} a fixed, absolute {x y} point
- {<anchor_collection>} a point that follows an anchor object
- {<anchor_collection> <position> <offset_x> <offset_y>} a point that follows an anchor object at the specified position and offset
- {<offset_x><+/-> <offset_y><+/->} a point that follows the location of the previous point in the list, at the specified offset

The first format describes a simple fixed point at an absolute coordinate.

The second format specifies that the point follow the center of the anchor object, where "center" is the center of the largest box that can be contained within the boundary of an anchor object.

The third format specifies that the point follow the anchor object at the specified offset with respect to the specified position. The x and y offset values can either be absolute distances or percentage values (which are appended with '%'). The valid position values are as follows:

- center: The center of the largest box within the anchor object
- bbox_center: The center of the bounding box of the anchor object
- bbox_ll: The lower-left corner of the bounding box of the anchor object
- bbox_ul: The upper-left corner of the bounding box of the anchor object
- bbox_lr: The lower-right corner of the bounding box of the anchor object
- bbox_ur: The upper-left corner of the bounding box of the anchor object

This is a required option.

`-name` *`annotation_name`*

Specifies the name of the annotation_shape. The name might not contain the special character '/'. If unspecified, the command generates a name automatically using the prefix "ANNOTATION_SHAPE" with a system-generated number appended.

`-category` *`category_name`*

Specifies the name of the category the annotation_shape object. The category maybe used for grouping of annotation shapes into separate sets. If unspecified, the category will not be assigned for the annotation_shape.

Feedback

`-fit_symbol`

Creates the rectangle based fit_symbol annotation shape.

`-width` *`width`*

Specifies the width of a fit_symbol annotation_shape object. The value must be more than 0.

If you use this option without "-fit_symbol", the tool issues an error.

`-height` *`height`*

Specifies the height of a fit_symbol annotation_shape object. The value must be more than 0.

If you use this option without "-fit_symbol", the tool issues an error.

`-size` *`font_size`*

Specifies the size of symbol in pixels. The default size of a symbol is 16. The range is from 3 to 100.

`-color` *`color`*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes might be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette.

`-fill` *`pattern`*

Specifies the annotation fill pattern. The supported values for this option are: BDiagPattern, CrossPattern, Dense1Pattern, Dense2Pattern, Dense3Pattern, Dense4Pattern, Dense5Pattern, Dense6Pattern, Dense7Pattern, DiagCrossPattern, FDiagPattern, HorPattern, NoBrush, SolidPattern, and VerPattern. The default fill pattern is NoBrush.

`-pen_style` *`pen_style`*

Specifies the annotation pen style. The supported values for this option are: CustomDashLine, DashDotDotLine, DashDotLine, DashLine, DotLine, NoPen, and SolidLine. The default pen style is SolidLine.

`-pen_width` *`pen_width`*

Specifies the annotation pen width. The default pen width is 1 pixel.

Feedback

`-orientation` *orientation*

Specifies the orientation of an annotation symbol.

Valid values are

- *MX* (mirror around the X-axis)
- *MXR90* (mirror around the X-axis and rotate 90 degrees)
- *MY* (mirror around the Y-axis)
- *MYR90* (mirror around the Y-axis and rotate 90 degrees)
- *R0* (no rotation, which is the default)
- *R90* (rotate 90 degrees)
- *R180* (rotate 180 degrees)
- *R270* (rotate 270 degrees)

`-file` *file_path*

Specifies the location of symbol file in SVG format. Only <path> elements should be used to draw symbol shapes. All <path> commands with exception of 'elliptical Arc' are supported.

The custom symbol files can be placed in a annotation symbol directory and accessed by file name only. Annotation symbol directory can be set with application option: set_app_options -name gui.annotation_symbol_dir -value <dir>.

The SVG files are parsed once and cached to make rendering fast.

The color, pen style, and fill are set from the corresponding options. Any SVG editor maybe used for creating and editing symbols.

This is a required option for symbol type "custom".

`-design` *design*

Specifies the design in which to create the annotation_shapes of type symbol. If no design is specified, the annotation_shapes are created in the current design.

Description

This command creates new annotaion_shape of type symbol and returns a collection that contains the new annotation_shape. The annotation symbol is zoom-independent and its size does not alter when you change the zoom level for viewed physical design in the block window.

Feedback

Examples

The following example creates a red diamond annotation_shape symbol with CrossPattern fill.

```
prompt> create_annotation_symbol -type diamond -origin {430.490 629.800}
 \\
  -name annoDiamond -size 15 -color red -fill CrossPattern \\
  -pen_style SolidLine -pen_width 2
```

The following example creates a green square annotation_shape symbol with SolidPatterm fill.

```
prompt> create_annotation_symbol -type square -origin {534.440 629.800}
 \\
  -name annoSquare -size 15 -color green -fill SolidPattern \\
  -pen_style DotLine -pen_width 1
```

The following example creates a blue triangle annotation_shape symbol in the center of cell 'I_CLOCK_GEN/I_PLL_PC' with Dense7Pattern fill.

```
prompt> create_annotation_symbol -type triangle \\
  -origin [list [get_cells I_CLOCK_GEN/I_PLL_PCI]] -name annoTriangle
 -size 15 \\
  -color blue -fill Dense7Pattern -pen_style SolidLine -pen_width 1
```

---

create_annotation_text

Creates an annotation_shape object of type text in the current design.

Syntax

```
collection create_annotation_text
-text text_string
-origin annotation_point
```

Feedback

```
[-name annotation_name]
[-category  category_name]
[-font_size font_size]
[-color color]
[-horizontal_alignment left | center | right]
[-vertical_alignment bottom | middle | top]
[-orientation orientation]
[-bold_text]
[-design design]
```

Data Types

```
text_string         string
annotation_point    location descriptor
annotation_name     string
category_name       string
font_size           integer
color               string
orientation         string
design              string
```

Arguments

`-text`

Specifies the annotation text string.

This is a required option.

`-origin annotation_point`

Specifies the annotation text origin point. The point is specified by a tool command language (Tcl) list of the following format:

- {<coord_x> <coord_y>} a fixed, absolute {x y} point
- {<anchor_collection>} a point that follows an anchor object
- {<anchor_collection> <position> <offset_x> <offset_y>} a point that follows an anchor object at the specified position and offset

The first format describes a simple fixed point at an absolute coordinate.

The second format specifies that the point follow the center of the anchor object, where "center" is the center of the largest box that can be contained within the boundary of an anchor object.

The third format specifies that the point follow the anchor object at the specified offset with respect to the specified position. The x and y offset values can either

Feedback

be absolute distances or percentage values (which are appended with '%'). The valid position values are as follows:

- center: The center of the largest box within the anchor object
- bbox_center: The center of the bounding box of the anchor object
- bbox_ll: The lower-left corner of the bounding box of the anchor object
- bbox_ul: The upper-left corner of the bounding box of the anchor object
- bbox_lr: The lower-right corner of the bounding box of the anchor object
- bbox_ur: The upper-left corner of the bounding box of the anchor object

This is a required option.

`-name` *`annotation_name`*

Specifies the name of the annotation_shape. The name might not contain the special character '/'. If unspecified, the command generates a name automatically using the prefix "ANNOTATION_SHAPE" with a system-generated number appended.

`-category` *`category_name`*

Specifies the name of the category the annotation_shape object. The category maybe used for grouping of annotation shapes into separate sets. If unspecified, the category will not be assigned for the annotation_shape.

`-font_size` *`font_size`*

Specifies the size of an application font in points. There are approximately 72 (72.272) points in one inch. The default font size is 10. The range is from 1 to 100.

`-color` *`color`*

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white. Annotations use colors from the qt color palette by default. Colors from other color palettes might be used by specifying a color name qualified with a palette name. For example, "red:highlight" specifies the red color from the highlight palette. Available palettes are qt, highlight, highcontrast, and style. Use gui_get_color_value command to report on color names and values available in a palette.

`-horizontal_alignment left | center | right`

Specifies the horizontal alignment of the text with respect to the origin point. The default is center.

Feedback

`-vertical_alignment bottom | middle | top`

Specifies the vertical alignment of the text with respect to the origin point. The default is middle.

`-orientation` *orientation*

Specifies the orientation of an annotation text.

Valid values are

- *MX* (mirror around the X-axis)
- *MXR90* (mirror around the X-axis and rotate 90 degrees)
- *MY* (mirror around the Y-axis)
- *MYR90* (mirror around the Y-axis and rotate 90 degrees)
- *R0* (no rotation, which is the default)
- *R90* (rotate 90 degrees)
- *R180* (rotate 180 degrees)
- *R270* (rotate 270 degrees)

`-bold_text`

Specifies to use bold font for the text.

`-design` *design*

Specifies the design in which to create the annotation_shapes of type text. If no design is specified, the annotation_shapes are created in the current design.

Description

This command creates new annotaion_shape of type text and returns a collection that contains the new annotation_shape. The annotation text is zoom-independent and its size does not alter when you change the zoom level for viewed physical design in the block window. You can use new line character \\n for multiline texts.

Examples

The following example creates an annotation_shape of type text with text string "Text1", font size 12 points, oriented horizontally.

```
prompt> create_annotation_text -text Text1 -origin {969.370 1204.625} \\
  -name annoText1 -font_size 12 -color red \\
  -horizontal_alignment center -vertical_alignment middle
```

The following example creates an annotation_shape of type text with text string "Text2", font size 12 points, oriented vertically.

Feedback

```
prompt> create_annotation_text -text Text2 -origin {969.370 1204.625} \\
  -name annoText2 -font_size 12 -color green \\
  -horizontal_alignment center -vertical_alignment middle -orientation
 vertical
```

The following example creates an annotation_shape of type text with 2-line text string "Text3\\nText4", font size 14.

```
prompt> create_annotation_text -text "Text3\\nText4" -origin {1000.370
 1204.625} \\
  -name annoText3 -font_size 14 -color red
```

The following example creates an annotation_shape of type text with text string "Text5" with origin offset 25% along x and y directions from the center of anchor object. Default font size is 10.

```
prompt> set object [get_cells I_ORCA_TOP/I_PCI_CORE]
  create_annotation_text -text "Text5" -origin [list $object bbox_center
 25% 25%] -color yellow
```

---

create_assignment_statement

Creates 1 RTL assignment statement.

Syntax

collection *create_assignment_statement*

```
-lvalue lvalue
-rvalue rvalue
[-blocking]
[-module module | -cell cell]
[-scope scope]
```

Feedback

Data Types

```
lvalue      collection
rvalue      collection
module      collection
cell        collection
scope       collection
```

Arguments

`-lvalue` *lvalue*

Specifies the statement type variable used as the variable for the assignment statement. This is a required argument. The *lvalue* can a net, port, busNet, busPort, literal, or expression.

`-rvalue` *rvalue*

Specifies the rtl_statement of type expression to be used to assign to the variable. This is a required argument. The *rvalue* can a net, port, busNet, busPort, literal, or expression.

`-blocking`

Creates a blocking assignment.

`-module` *module*

Specifies the module to create the assignment statement in. This option is mutually exclusive with the *-cell* option.

`-cell` *cell*

Specifies the cell to create the assignment statement in. This option is mutually exclusive with the *-module* option.

`-scope` *scope*

Adds the newly created assignment statement in the scope provided by the RTL statement.

Description

This command creates an RTL assignment statement. The assignment statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the assignment statement is created in the current instance.

Examples

The following example creates 1 assignment statement in the top most module, assigning the *rtl_expression_10* expression to the *left* variable.

```
prompt > create_assignment_statement -lvalue [get_statements -filter
 "type == variable" left] \\
```

Feedback

```
-rvalue [get_statements -filter "type == expression" expression_10] \\
{"RTL_ASSIGNMENT_40"}
```

See Also

- get_statements
- remove_statements

---

create_backend_tcd_cells

Inserts back-end testkey critical dimension cells (TCDs) into the design.

Syntax

status *create_backend_tcd_cells*

```
-lib_cells layer_lib_cells
-window_size {width height}
[-tcd_spacing {dist_layer1_layer2}]
[-other_cell_spacing {dist_layer}]
[-icovl_spacing {dist_layer}]
[-stack_with_macro layer_list]
[-stack_with_frontend layer_list]
[-stack_with_backend {layer_list}]
[-avoid_route_guide {layer_list}]
[-density {density_layer}]
[-orientation {orient_layer}]
[-check_only]
[-include_small_windows]
[-bbox {{x1 y1} {x2 y2}}]
[-snap_to_fin_grid]
[-place_at_window_center]
[-combined_tcd_cells]
```

Data Types

```
layer_lib_cells     string
width               float
height              float
layer_libcells      string
dist_layer1_layer2  string
dist_layer          string
layer_list          list
density_layer       string
orient_layer        string
```

Feedback

Arguments

`-lib_cells` *`layer_lib_cells`*

Specifies the metal layer and corresponding back-end TCD library cells. For example, { {M1 cell1 cell2} {M2 cell3 cell4} } specifies back-end TCD library cells cell1 and cell2 are for layer M1; library cells cell3 and cell4 are for layer M2.

`-window_size` *`{width height}`*

Specifies width and height of insertion window size.

`-tcd_spacing` *`{ dist_layer1_layer2}`*

Specifies the minimum distance between two layers of back-end TCD cells. For example, {{10 M1 M4} {20 M2 M3} } specifies that the spacing between M1 and M4 TCD cells is 10um, and the spacing between M2 and M3 TCD cells is 20um. If no spacing value is specified, the default spacing is 0um and TCD cells can abut but cannot overlap. The command issues an error message if two back-end TCD layers have a spacing rule specified with *-tcd_spacing* and also have an overlap specified with *-stack_with_backend*.

`-other_cell_spacing` *`{dist_layer}`*

Specifies the minimum distance between back-end TCD cells with non back-end TCDs and ICOVL cells. This rule does not apply to cells specified with the *-stack_with_macro* and *-stack_with_frontend* options. For example, { { 10 M1} {10 M3 } { 20 M2 } } specifies that the minimum spacing between a M1 back-end TCD and a non back-end TCD cell is 10um, and the minimum spacing between a M3 back-end TCD and a non back-end TCD cell is also 10um, and the minimum spacing between a M2 back-end TCD and a non back-end TCD cell is 20um. By default, the default spacing is 0um and cells can abut but cannot overlap.

`-icovl_spacing` *`{ dist_layer}`*

Specifies the spacing between back-end TCDs and ICOVL cells. For example, { { 10 M1} {10 M4} { 20 M2} {20 M3} } specifies that the spacing between ICOVL cell and M1, M4 layer back-end TCDs is 10um, and the spacing between ICOVL cells and M2 and M3 layer back-end TCDs is 20um. By default, the default spacing is 0um and cells can abut but cannot overlap.

`-stack_with_macro` *`layer_list`*

Specifies a list of back-end TCD metal layers that are allowed to stack with macros. For example, {M1 M5} specifies that M1 layer back-end TCDs can stack with macros without M1 layer metal objects, and M5 back-end TCDs can stack with macros without M5 layer metal objects. Other metal layer back-end TCDs are not allowed to stack with any macros. Note that the command will only check if a macro containing any top-level objects on the specified metal layers. It will not open and check cells inside a macro.

Feedback

`-stack_with_frontend` *layers*

Specifies a list of back-end TCD metal layers that can overlap with frontend TCDs. For example, { M1 M3 } specifies that M1 and M3 layer backend TCDs can overlap with frontend TCDs.

`-stack_with_backend` *{layer_list}*

Specifies which layers of back-end TCDs can overlap. For example, { { M1 M2} { M3 M4 } } specifies that back-end TCDs of M1 and M2 layers can overlap, and back-end TCDs of M3 and M4 layers can overlap.

`-avoid_route_guide` *{layer_list}*

Specifies which layer of back-end TCDs must avoid route guides and routing blockages on another layer. For example, { { M1 M3 } { M2 M4 } } specifies that M1 layer back-end TCDs should avoid route guides and routing blockages of layer M3; and M2 layer back-end TCDs should avoid route guides and routing blockages for layer M4.

`-density` *{density_layer}*

Specifies the target percentage of windows that contain a back-end TCD cell. For example, { {80 M1} {80 M3} { 50 M2} } specifies that the target density for M1 layer and M3 layer back-end TCDs is 80%, and the target density for M2 layer back-end TCDs is 50%. The command tries to evenly distribute the TCDs. For example, if the target density is 50%, it tries to insert one back-end TCD for every other window. By default, the density is 100% and each window should have one back-end TCD.

`-orientation` *{orient_layer}*

Specifies the back-end TCD orientation. Valid orientation values are R0, R90, R180, R270, MX, MXR90, MY, MYR90. For example, { {R0 M1} {R0 M2} { MX M3} {MX M4} } specifies that M1 and M2 layer back-end TCDs have an orientation of R0, and M3 and M4 layer back-end TCDs have an orientation of MX. If the specified orientation is not one of TCD cell's allowable orientation (attribute allowable_orientation), the command issues a warning message. By default, the orientation is N.

`-check_only`

Checks the current design for back-end TCD violations based on rules specified in other options. An error message is issued for each violation.

`-include_small_windows`

Includes small windows at the last row/column for TCD insertion. By default, these small windows are excluded.

Feedback

`-bbox` *`{{x1 y1} {x2 y2}}`*

Specifies an insertion area. This area is divided into the specified window size for TCD insertion. By default, the core area is the insertion area.

`-snap_to_fin_grid`

Places the lower-left corner of the TCD cell to align with the FinFET grid. By default, alignment is not required.

`-place_at_window_center`

Changes the placement preference of TCD to be close to window center when specified to:

1. Place TCD in center of window 2. Stack with cells specified in -stack_with_* options 3. Place TCD in the channel between blocks or IPs (if blocks are not abut) 4. Place TCD at blocks or IP corner

By default, TCD cells are not placed at the center of window.

`-combined_tcd_cells`

Treat the cell is a combined front-end and back-end TCD cell. Placement blockages will be generated when combined TCD cells are placed.

Description

This command inserts back-end testkey critical dimension cells (back-end TCDs), which are used to increase design for manufacturability (DFM) and yield.

Back-end TCDs are inserted after power planning and contain only one metal layer. You can stack back-end TCDs over front-end TCDs to save placement area.

TCD width and height are not even multiples of unit tile width and height. They are placed as are regular macros.

Back-end TCDs may stack with front-end TCDs. back-end TCDs with metal layer M cannot place over layer M routing. If a front-end TCD is on layer M routing, then a back-end TCD with metal layer M cannot stack with this front-end TCD.

Back-end TCD insertion should prevent core cell area penalty by honoring the following insertion priority:

- Place the cell at the center of the window if *-place_at_window_center* option is specified
- Stack the cell with cells specified in stack_with_* option
- Place the cell in the channel between blocks or IPs (if blocks are not abut)

Feedback

- Place the cell in blocks or IP corner
- Place the cell in the core area

Examples

The following example inserts the back-end TCD cells DM1 and DM2 into windows of width 1000 microns and height of 1200 microns. DM1 has its metal layer on M1. DM2 has its metal layer on M2. Spacing between DM1 is 10 microns. Spacing between DM2 is 20 microns. Spacing between DM1 and other cells is 2 microns. Spacing between DM2 and other cells is 5 microns. DM1 can stack with front-end TCD cells.

```
prompt> create_backend_tcd_cells \\
   -lib_cells {{ M1 DM1} {M2 DM2}} -window_size {1000 1200} \\
   -tcd_spacing { { 10 M1} { 20 M2 } } \\
   -other_cell_spacing { { 2 M1 } { 5 M2 } \\
   -stack_with_frontend {M1}
```

See Also

- create_frontend_tcd_cells
- check_tcd_cells

---

create_backside_navigation

Remove vias on specified layer in a checkerboard pattern. Create routing blockages in place of the removed vias.

Syntax

status *create_backside_navigation*

```
-layer layer_name
-net net_name
[-x_pitch distance]
[-y_pitch distance]
[-x_offset distance]
[-y_offset distance]
[-within_bbox bounding_box]
```

Data Types

layer_name	string
net_name	string
distance	float
bounding_box	rectangle

Feedback

Arguments

`-layer` *layer_name*

It specifies cut layer name or via to be removed. User should pass a valid layer name and it only supports bv1 layer for now. This will error out if the layer name is not valid and if user passed any other layer apart from bv1 . This is the required option.

`-net` *net_name*

It specifies net name. User should pass a valid net name and also the net passed should be ground net vss or VSS. This will error out if the net name is not valid and if user passed any other type of net. This is the required option.

`-x_pitch` *distance*

Horizontal distance between two horizontal PG vias or stepping distance inx direction(xIncr). The default is 45. This is optional.

`-y_pitch` *distance*

Vertical distance perpendicular from the horizontal PG vias line to a PG via or stepping distance iny direction(yIncr). The default is 45. This is optional.

`-x_offset` *distance*

Horizontal offset from lower left of the block . The default is half of the pitch(45) = 22.5. This is optional.

`-y_offset` *distance*

Vertical offset from bottom left of the block . The default is half of the pitch(45) = 22.5. This is optional.

`-within_bbox` *bounding_box*

Specifies the region for the backside navigation. Provides list of coordinates from the box you want to remove the vias from in list format.Block core boundary is in format

`{{llx lly} {urx ury}}`

Description

Remove backside vias and add routing blockages in its place. For running this command layer_name and net_name are mandatory (required) arguments. This can be done in the whole design or within a specified rectangular boundary. If bbox is specified, command checks if existing via replacing routing blockages are present. If it exists it will do nothing and if it does not exist then it removes a via from center of the specified BBOX. This command is only available for ground net and not expected to work for any other type of nets.

Feedback

Examples

```
prompt> create_backside_navigation -layer bs_via_layer -net n311
 -within_bbox {{4.1100 48.3550} {0.3900 44.8150}}
```

---

create_begin_statement

Creates 1 RTL begin statement.

Syntax

collection *create_begin_statement*

```
[-name name]
[-module module | -cell cell]
[-scope scope]
```

Data Types

name	string
module	collection
cell	collection
scope	collection

Arguments

`-name` *name*

Specifies the name used for the begin statement.

`-module` *module*

Specifies the module to create the begin statement in. This option is mutually exclusive with the *-cell* option.

`-cell` *cell*

Specifies the cell to create the begin statement in. This option is mutually exclusive with the *-module* option.

`-scope` *scope*

Adds the newly created begin statement in the scope provided by the RTL statement.

Description

This command creates an RTL begin end statement. The begin end statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the begin end statement is created in the current instance.

Feedback

Examples

The following example creates 1 begin statement in the current instance.

```
prompt> create_begin_statement \\
   {"RTL_BEGIN_END_97"}
```

See Also

- get_statements
- remove_statements

---

create_blackbox

Creates a black box design and updates the reference for the specified cell.

Syntax

status *create_blackbox*

```
[-new_name bb_name]
[-type physical | macro]
[-library lib_name]
[-target_boundary_area area]
[-boundary boundary]
cell
```

Data Types

```
bb_name    string
lib_name   string
area       float
boundary   list
cell       list
```

Arguments

`-new_name bb_name`

Specifies the name of the new design. This is an optional argument. This option is only used when creating blackbox on a cell that has unresolved reference. It is ignored if the command is issued on a successfully bound logical hierarchy cell. By default, the command creates a design with the same name as the current reference of the specified cell.

`-type physical | macro`

Specifies the type of black box to create. Physical black boxes are physical blocks and follow the Physical Partition Design Planning Flow. The logical or macro type black boxes are created for unbound instances and empty

Feedback

hierarchies. After creating the black box, it is treated as any other macro in the design and is placed by the macro placer. The default type is physical.

`-library` *`lib_name`*

Specifies the library in which to create the new design. This is an optional argument. By default, the new design is created in the current library. If specified, the library must be one of the reference libraries for the library which contains the current design.

`-target_boundary_area` *`area`*

Specifies the target area of the black box design.

This option is mutually exclusive with *-boundary*.

`-boundary` *`boundary`*

Specifies the boundary for the black box design.

This option is mutually exclusive with *-target_boundary_area*.

`cell`

Specifies a cell whose reference is to be converted to a black box. The list can contain names, patterns, or collections. The cell must be a logical hierarchy cell or a cell with unresolved reference. All other cells in the design with the same reference, would have their reference changed to the black box as well.

Description

When the specified cell has unresolved reference, this command creates a new empty design with the same port interface as the unresolved reference of the cell. The reference of the cell and all other cells with the same unresolved reference is changed to the new design. Any other cells in designs linked to this design as child designs, or designs where this design is linked with the same unresolved reference, are updated as well.

When the specified cell is a logical hierarchy cell, the *create_blackbox* command converts the cell into a physical block and creates a new design with the content of the original cells logical hierarchy. The reference of the cell and all other cells with the same reference is changed to the new design.

The new design created by this command is a black box typed design.

To query the instances that are unbound, use the is_unbound attribute. For empty hierarchies, use the is_empty attribute.

After creating the black box, use the design_type==black_box filter expression to search for physical black boxes. Use the is_logical_black_box attribute for macro style black boxes.

Feedback

Examples

The following example creates a new design in the test library by using the port interface and name of the reference of the cell p0. The reference of this cell is unresolved at this point.

```
prompt> create_blackbox -library test p0
1
```

The following example commits the logical hierarchy cell p0 to a physical block and marks the reference block design as black box. The black box design's target_boundary_area is set to 10000.

```
prompt> create_blackbox -target_boundary_area 10000 p0
1
```

See Also

- get_cells

---

create_blackbox_clock_network_delay

Specifies the clock network delay for clock input ports or blackbox clocks.

Syntax

status *create_blackbox_clock_network_delay*

```
[-max | -min]
[-modes mode_list]
[-corners corner_list]
-value delay_value
from_objects
```

Data Types

```
mode_list    list
corner_list  list
delay_value  float
from_objects ports or blackbox clocks
```

Arguments

`-max`

Specifies that the network delay is for maximum delay (setup analysis) only. This option is mutually exclusive with *-min*. By default, when neither *-max* nor *-min* is specified, the network delay is applied to both min (hold) and max (setup).

Feedback

`-min`

Specifies that the network delay is for minimum delay (hold analysis) only. This option is mutually exclusive with *-max*. By default, when neither *-max* nor *-min* is specified, the network delay is applied to both min (hold) and max (setup).

`-modes` *`mode_list`*

Specifies the list of modes for which to apply the network delay. By default, the clock network delay is applied to all modes.

`-corners` *`corner_list`*

Specifies the list of corners for which to apply the network delay. By default, the clock network delay is applied to all corners.

`-value` *`delay_value`*

Specifies the network delay value.

`from_objects`

Specifies the input clock ports or blackbox clocks for which to apply the network delay. The specified ports must already be identified as clock ports with the *set_blackbox_clock_port* command. The specified blackbox clocks must already be create by the *create_blackbox_generated_clock* command.

Description

This command specifies clock network delay inside of the current block from the specified clock input ports or blackbox clocks. Clock ports are specified with the *set_blackbox_clock_port* command and blackbox clocks are create by the *create_blackbox_generated_clock* command before running the *create_blackbox_clock_network_delay* command.

Examples

The following example specifies that the maximum clock network delay from port *clk* is 1.2 for max and the minimum clock network delay is 1.0.

```
prompt> create_blackbox_clock_network_delay -max -value 1.2 clk
prompt> create_blackbox_clock_network_delay -min -value 1.0 clk
```

See Also

- commit_blackbox_timing
- set_blackbox_clock_port
- create_blackbox_generated_clock
- get_blackbox_generated_clocks

Feedback

create_blackbox_constraint

Creates setup and hold constraints for specified ports or blackbox clocks.

Syntax

```
status create_blackbox_constraint
-from from_objects
-edge rise | false
-to ports | -rise_to ports | -fall_to ports
[-setup | -hold]
[-modes mode_list]
[-corners corner_list]
[-clock clock]
-value delay_value
```

Data Types

```
from_objects port objects or blackbox clocks
mode_list    list of modes
corner_list  list of corners
clock        clock object
delay_value  float
```

Arguments

`-from from_objects`

Specifies the clock ports or blackbox clocks which the constraint is from.

`-edge rise | fall`

Specifies whether the constraint is from the rising edge or falling edge of the clock signal at the specified clock ports.

`-to ports`

Specifies the signal ports that the constraint is for. This creates a constraint for both rise and fall signal at the ports.

`-rise_to ports`

Specifies the signal ports that the constraint is for. This creates a constraint for the rising signal at the ports.

`-fall_to ports`

Specifies the signal ports that the constraint is for. This creates a constraint for the falling edge signal at the ports.

Feedback

`-setup`

Specifies that this is a setup constraint. This option is mutually exclusive with the *-hold* option. By default, when neither *-setup* nor *-hold* is specified, the constraint applies to both setup and hold.

`-hold`

Specifies that this is a hold constraint. This option is mutually exclusive with the *-setup* option. By default, when neither *-setup* nor *-hold* is specified, the constraint applies to both setup and hold.

`-modes` *`mode_list`*

Specifies the list of modes what the constraint is for. By default, the constraint is applied to all modes.

`-corners` *`corner_list`*

Specifies the list of corners that the constraint is for. By default, the constraint is applied to all corners.

`-clock` *`clock`*

Specifies that the constraint time value is the percentage of the given clock's period. The final value of the constraint is the clock period multiplied by the value specified with *-value* option. By default, the value specified with *-value* option is the absolute value for the constraint.

`-value` *`delay_value`*

Specifies the delay value for the constraint. When *-clock* is specified, this value means the constraint's value is a certain percentage of the clock period. Without *-clock*, the specified value is the final value for the constraint.

Description

This command defines setup and hold constraints from the specified edge of clock signal at the specified clock ports or blackbox clocks to the specified signal ports. The "from_objects" are clock ports defined by the *set_blackbox_clock_port* command or blackbox clocks defined by the *create_blackbox_generated_clock* command. The "to" ports can be either input or inout signal ports.

The value of the constraint can be described as an absolute value or as a percentage of a specified clock's period.

Examples

The following example defines constraints for signal rise at port *$data* from the clock's rising edge at clock port *clk*. The setup constraint value is 0.6. And the hold constraint value is 30 percent of main_clock's period.

Feedback

```
prompt> create_clock -name main_clock -period 10 [get_ports clk]
prompt> set_blackbox_clock_port clk
prompt> create_blackbox_constraint -from clk -edge rise -to $data -setup
 -value 0.6
prompt> create_blackbox_constraint -from clk -edge rise -to $data \\
  -clock main_clock -value 0.3 -hold
```

See Also

- commit_blackbox_timing
- create_blackbox_delay
- set_blackbox_clock_port
- create_blackbox_generated_clock
- get_blackbox_generated_clocks

---

create_blackbox_delay

Specifies delay paths between the specified ports or blackbox clocks.

Syntax

```
status create_blackbox_delay
-from from_objects | -rise_from from_objects | -fall_from from_objects
-to ports | -rise_to ports | -fall_to ports
[-max | -min]
[-modes mode_list]
[-corners corner_list]
[-clock clock]
-value delay_value
```

Data Types

```
from_objects port objects or blackbox clocks
mode_list    list of modes
corner_list  list of corners
clock        clock object
delay_value  float
```

Arguments

`-from from_objects`

Specifies the originating ports or blackbox clocks for the timing paths. This option is mutually exclusive with the *-rise_from* and *-fall_from* options. This option creates timing paths for both the rising and falling edges from the specified ports or blackbox clocks.

Feedback

`-rise_from` *`from_objects`*

Specifies the originating ports or blackbox clocks for the rising edge for the timing paths. This option is mutually exclusive with the *-from* and *-fall_from* options. This option creates timing paths for the rising edge to the specified ports or blackbox clocks.

`-fall_from` *`ports`*

Specifies the originating ports or blackbox clocks for the falling edge for the timing paths. This option is mutually exclusive with the *-from* and *-rise_from* options. This option creates falling timing paths for the specified ports or blackbox clocks.

`-to` *`ports`*

Specifies the destination ports for the timing paths. This option is mutually exclusive with the *-rise_to* and *-fall_to* options. This option creates timing paths for both the rising and falling edges to the specified ports.

`-rise_to` *`ports`*

Specifies the destination ports for the rising edge for the timing paths. This option is mutually exclusive with the *-to* and *-fall_to* options. This option creates timing paths for the rising edge to the specified ports.

`-fall_to` *`ports`*

Specifies the destination ports for the falling edge for the timing paths. This option is mutually exclusive with the *-to* and *-rise_to* options. This option creates timing paths for the falling edge to the specified ports.

`-max`

Specifies that the value is for the maximum delay (setup analysis) only. This option is mutually exclusive with the *-min* option. By default, when neither *-max* nor *-min* is specified, the value applies to both minimum (hold) and maximum (setup).

`-min`

Specifies that the value is for the minimum delay (hold analysis) only. This option is mutually exclusive with the *-max* option. By default, when neither *-max* nor *-min* is specified, the value is for both minimum (hold) and maximum (setup).

`-modes` *`mode_list`*

Specifies the list of modes that the value applies to. By default, the delay path value is applied to all modes.

Feedback

`-corners` *corner_list*

Specifies the list of corners that the value applies to. By default, the delay path value is applied to all corners.

`-clock` *clock*

Specifies that the value is the percentage of the given clock's period. The final delay value for the path is the clock period multiplied by the value specified with *-value* option. By default, the value specified with *-value* option is the absolute delay value for the paths.

`-value` *delay_value*

Specifies the path delay value. When *-clock* is specified, this value means that the path delay is the specified percentage of the clock period. If the *-clock* option is not specified, the *delay_value* is the delay value for the paths.

Description

This command defines a set of paths between a set of ports or blackbox clocks and a set of ports as part of the black box timing information. The "from_objects" can be ports or blackbox clocks. The ports can be either input ports or inout ports and can be signal ports or clock ports. The blackbox clocks are created by the *create_blackbox_generated_clock* command. The "to" ports can be either output inout signal ports. Clock ports are specified with the *set_blackbox_clock_port* command before running this command.

The delay value for a path can be described as an absolute value or as a percentage of a specified clock's period.

For a partial netlist, the "to" ports must be ports with no block internal net connection in the original design netlist.

Examples

The following example defines a path that rises from port *DataIn* and rises to port *DataOut* with a delay of 0.6 for setup analysis and 0.5 for hold analysis.

```
prompt> create_blackbox_delay -rise_from DataIn -rise_to DataOut -value
 0.6 -max
prompt> create_blackbox_delay -rise_from DataIn -rise_to DataOut -value
 0.5 -min
```

The following example defines a path from the rising edge of main_clock to the rising or falling edge of port *DataOut*. The delay value is 30 percent of the clock period for main_clock.

```
prompt> create_clock -name main_clock -period 10 [get_ports ClkIn]
prompt> set_blackbox_clock_port ClkIn
prompt> create_blackbox_delay -rise_from ClkIn -to DataOut -clock
 main_clock -value 0.3
```

---

create_blackbox_drive_type

Creates an output drive type for black box timing.

Syntax

```
status create_blackbox_drive_type
-lib_cell lib_cell_object
[-input_transition_rise transition_time]
[-input_transition_fall transition_time]
name
```

Data Types

```
lib_cell_object  string
transition_time  float
name  string
```

Arguments

`-lib_cell lib_cell_object`

Specifies the buffer or inverter library cell as the driver cell for this drive type.

`-input_transition_rise transition_time`

Specifies the rise transition time at the input pin of the driver cell. The default is zero.

`-input_transition_fall transition_time`

Specifies the fall transition time at the input pin of the driver cell. The default is zero.

`name`

Specifies the name for this drive type. Commands such as *set_blackbox_port_drive* can use this name to identify the drive type.

Feedback

Description

This command creates an output port drive type as part of the black box timing information for the current block.

The drive type created by this command can be used by the *set_blackbox_port_drive* command to describe the driver of a particular port.

Examples

The following example defines the driver at output port *DataOut* as a cell whose reference library cell is *BUF8* in reference library *stdreflib1* with 0.01ns rise and fall transition time at the input pin.

```
prompt> create_blackbox_drive_type -lib_cell [get_lib_cells
 stdreflib1/BUF8] \\
        -input_transition_rise 0.01 -input_transition_fall 0.01
 driveType1
prompt> set_blackbox_port_drive -type driveType1 [get_ports DataOut]
```

---

create_blackbox_generated_clock

Creates a blackbox generated clock object.

Syntax

```
collection create_blackbox_generated_clock
-name clock_name
[-source master_pin]
[-divide_by divide_factor | -multiply_by multiply_factor |
[-invert]
-master_clock clock
```

Data Types

```
clock_name          string
master_pin          list
divide_factor       int
multiply_factor     int
clock               string
```

Feedback

Arguments

`-name` *clock_name*

Specifies the name of the blackbox generated clock. The name must have not been used by other clocks. This option is required.

`-source` *master_pin*

Specifies the master clock source (a clock source pin in the design) from which to derive the clock waveform.

`-divide_by` *divide_factor*

Specifies the frequency division factor. If the *divide_factor* value is *2*, the blackbox generated clock period is twice as long as the master clock period. This option cannot be used together with option *-multiply_by*.

`-multiply_by` *multiply_factor*

Specifies the frequency multiplication factor. For example, if the *multiply_factor* value is *3*, the blackbox generated clock period is one-third as long as the master clock period. This option cannot be used together with option *-divide_by*.

`-invert`

Inverts the blackbox generated clock signal in the case of frequency multiplication and division.

`-master_clock` *clock*

Specifies the master clock to be used for this blackbox generated clock. This option is required.

Description

Creates a blackbox generated clock object in the blackbox timing model. The blackbox generated clock object is available for use with the *create_blackbox_delay*, *create_blackbox_constraint*, and *create_blackbox_clock_network_delay* commands. Use the *get_blackbox_generated_clocks* command to get the blackbox generated clock objects.

The command can specify the clock source from which it is generated. You must specify the master clock for this generated clock. If the source pin/port is not specified, the specified master clock must have a source pin/port.

The blackbox generated clock can be created as a frequency divided clock (by using the *-divide_by* option), frequency multiplied clock (by using the *-multiply_by* option), or special divide by one (by setting *divide_factor* or *multiply_factor* as 1). The frequency divided or frequency multiplied clock can be inverted by using the *-invert* option.

Feedback

Examples

The following example creates a frequency divide_by 2 blackbox generated clock.

```
prompt> create_clock -period 1 -name CLK CLK
prompt> create_blackbox_generated_clock -name GCK -divide_by 2 \\
   -source CLK -master_clock CLK
prompt> get_blackbox_generated_clocks GCK
{GCK}
```

See Also

---

create_blackbox_load_type

Creates an input load type for black box timing.

Syntax

```
status create_blackbox_load_type
-lib_cell lib_cell_object
name
```

Data Types

```
lib_cell_object string
name            string
```

Arguments

`-lib_cell` *lib_cell_object*

Specifies the buffer or inverter library cell as the load cell for this load type.

`name`

Specifies the name for this load type. Commands such as *set_blackbox_port_load* can use the name to identify the load type.

Description

This command creates an input port load type as part of the black box timing information for the current block.

Feedback

The load type created by this command can be used by the *set_blackbox_port_load* command to describe the load of a particular port.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example defines the load at input port *DataIn* as being five *BUF8* cells from the reference library *stdreflib1*.

```
prompt> create_blackbox_load_type -lib_cell [get_lib_cells
 stdreflib1/BUF8] loadType1
prompt> set_blackbox_port_load -type loadType1 -factor 5 [get_ports
 DataIn]
```

See Also

- create_blackbox_drive_type
- commit_blackbox_timing
- set_blackbox_port_drive
- set_blackbox_port_load

---

create_block

Creates a new block or overwrite an existing block in a module library.

Syntax

collection *create_block*

```
[-boundary poly_rect]
[-dimensions {width height}]
[-design_type type]
[-dont_set_current]
[-origin_type bottom_left | center]
[-force]
block_name
```

Data Types

```
block_name      string
```

Feedback

Arguments

`-boundary`

An optional argument that defines the physical boundary of the block. The boundary shape must be rectilinear. Mutually exclusive with "-dimensions".

`-dimensions`

An optional argument that defines the width and height of the block. The resulting block boundary is rectangular with the given width and height. Both width and height must be greater than 0. Mutually exclusive with "-boundary".

`-design_type`

An optional argument to specify the design_type for the block. The design types "bridge" and "substrate" are deprecated.

`-dont_set_current`

An optional argument to create the block without setting it as the current block.

`-origin_type`

An optional argument to specify the origin point for the block boundary. The default setting is "bottom_left". A value of "bottom_left" aligns the specified boundary such that the lower left corner of the bounding box is at (0, 0). A value of "center" aligns the specified boundary such that the central point of the bounding box is at (0, 0).

`-force`

This option is used to overwrite the block if it already exists in the target library.

`block_name`

The name of the block to create, with optional library, label, and view specifications. This is specified as follows:

[libName:]blockName[/labelName][.viewName]

If the library specification is not present, the *current_lib* is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then design is used.

Description

This command creates a new block with an empty top module. It can also be used to re-initialize an existing block into an empty one. The top module name will match the new or re-initialized block. The top module of the block is made the current block. The open-mode will be set to "new". The open_count is (re-)set to 1.

Feedback

The user may optionally specify a boundary geometry and design type for the block. The command determines the boundary using either "-dimensions" or "-boundary", along with "-origin_type". The boundary becomes either a rectangle with given width and height (-dimensions) or a custom rectilinear shape (-boundary) that is either lower-left or center aligned at (0, 0). Furthermore, the user may choose to create a block without changing the current_block setting by using "-dont_set_current".

This command returns a collection of the newly created block if successful, or "" if not. If an illegal name ('/', or empty space) is given, then a TCL error is raised.

Examples

The following example creates a block "top" in library "r4000":

```
prompt> create_block r4000:top
{"r4000:top.design"}

The following example creates a block "top" with a rectangular boundary
from (0, 0) to (100, 100) and sets the design type to "black_box":

prompt> create_block top -dimensions {100 100} -design_type black_box
{"myLib:top.design"}

The following example creates a block "top" with a custom boundary
 centered
at (0, 0) and doesn't change the current_block:

prompt> create_block top -boundary {{10 10} {10 70} {30 70} {30 55} {40
 55} {40 10}} -origin_type center -dont_set_current
{"myLib:top.design"}
```

Feedback

- reopen_block
- save_block
- create_block_cell

---

create_block_cell

Creates a new block or overwrites an existing block in a module library, followed by an instantiation of the block in the current block context.

Syntax

collection *create_block_cell*

```
-name cell_name
-block_name block_name
-design_type type
[-boundary poly_rect]
[-design design]
[-dimensions {width height}]
[-origin_type bottom_left | center]
[-origin coord]
[-force]
block_name
```

Data Types

```
block_name      string
```

Arguments

`-name`

A required argument that gives the name of the cell to create.

`-block_name`

A required argument that gives the name of the block to create or replace.

`-design_type`

A required argument that specifies the design_type for the block. The design types "bridge" and "substrate" are deprecated.

`-boundary`

An optional argument that defines both the physical boundary of the block and the placement location of the cell. The boundary shape must be rectilinear. Mutually exclusive with "-dimensions" and "-origin".

Feedback

`-design`

An optional argument that specifies the context in which to instantiate the resulting cell. Allows for cell creation in sub-levels of hierarchy. By default the command uses the current design.

`-dimensions`

An optional argument that defines the width and height of the block. The resulting block boundary is rectangular with the given width and height. Both width and height must be greater than 0. Mutually exclusive with "-boundary". Requires "-origin".

`-origin_type`

An optional argument to specify the origin point for the block boundary. The default setting is "bottom_left". A value of "bottom_left" aligns the specified boundary such that the lower left corner of the bounding box is at (0, 0). A value of "center" aligns the specified boundary such that the central point of the bounding box is at (0, 0).

`-origin`

An optional argument to specify the origin location for cell placement. Mutually exclusive with "-boundary". Requires "-dimensions".

`-force`

This option is used to overwrite the block if it already exists in the target library.

`block_name`

The name of the block to create, with optional library, label, and view specifications. This is specified as follows:

[libName:]blockName[/labelName][.viewName]

If the library specification is not present, the *current_lib* is used. If the label specification is not present, the default un-named label is used. If the view specification is not present, then design is used.

Description

The command both creates a block and instantiates it in the current design context, unless the user has specified a different context using "-design". If the user does not specify a design and the current_block is not set, the command fails. The command procedure is essentially a combination of create_block followed by create_cell.

Regarding the block creation, the command requires a design type and boundary definition for the block. The command determines the boundary using either "-dimension" or "-boundary", along with "-origin_type". The boundary becomes either a rectangle with given width and height (-dimensions) or a custom rectilinear shape (-boundary)

Feedback

that is either lower-left or center aligned at (0, 0). Furthermore, the user may choose to replace an existing block using "-force", as well as create a block without changing the current_block setting by using "-dont_set_current".

Regarding the cell creation, the command requires a cell name and origin for placement. When using "-dimensions", the origin is taken from the "-origin" argument. When using "-boundary", the origin is derived from the boundary location interpreted in the context of the current design. The command fails if a cell of the same name already exists in the current level of hierarchy.

The command returns the created cell upon success.

Examples

The following example creates a block "bb1" with a boundary of "{-25 -30} {-25 30} {15 30} {15 10} {25 10} {25 -30}" and places an instantiation of that block named "BB1" at {35 40}.

```
prompt> create_block_cell -name BB1 -block_name bb1 -design_type
 black_box -boundary {{10 10} {10 70} {50 70} {50 50} {60 50} {60 10}}
 -origin_type center
{""}

The following example creates a block "bb2" with a boundary of "{5 1} {5
 21} {45 21} {45 1}" and
places an instantiation of that block named "BB2" at {5 1}.

prompt> create_block_cell -name BB2 -block_name bb2 -design_type
 black_box -dimensions {40 20} -origin {5 1}
```

See Also

- create_block
- create_cell

---

create_block_pin_constraint

Creates a block_pin_constraint in the current block.

Syntax

```
collection create_block_pin_constraint
[-allowed_layers metal_layers]
[-corner_keepout_track_count number_of_tracks]
[-corner_keepout_distance distance]
[-pin_spacing_track_count number_of_tracks]
[-pin_spacing_distance distance]
[-sides side_numbers]
[-excluded_sides side_numbers]
[-allow_feedthroughs]
```

Feedback

```
[-stacking_type any | none | with_pg_pins_only | with_signal_pins_only]
[-width pin_width]
[-length pin_length]
[-hard_constraints constraint_types]
[-cells cell_list]
```

Data Types

```
metal_layers      collection
number_of_tracks  integer
distance          float
side_numbers      list
pin_width         float
pin_length        float
constraint_types  list
cell_list         collection
```

Arguments

`-allowed_layers` *metal_layers*

Specifies the set of metal layers allowed for pin placement. If unspecified, by default, all metal layers from the minimum routing layer up through the maximum routing layer are allowed for pin placement.

`-corner_keepout_track_count` *number_of_tracks*

Specifies the number of wire tracks from the block corners where pin placement should begin. Value must be >= 0. This option defaults to 5 if neither -corner_keepout_track_count nor -corner_keepout_distance option is specified. The -corner_keepout_track_count and -corner_keepout_distance options are mutually exclusive.

`-corner_keepout_distance` *distance*

Specifies the distance in microns from the block corners where pin placement should begin. Value must be >= 0. The corner keepout track count default of 5 wire tracks is used if neither -corner_keepout_track_count nor -corner_keepout_distance option is specified. The -corner_keepout_track_count and -corner_keepout_distance options are mutually exclusive.

`-pin_spacing_track_count` *number_of_tracks*

Specifies the minimum number of wire tracks between adjacent pins, or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks. Value must be >= 0. This option defaults to 1 if neither -pin_spacing_track_count nor -pin_spacing_distance option is specified. The -pin_spacing_track_count and -pin_spacing_distance options are mutually exclusive.

Feedback

`-pin_spacing_distance` *`distance`*

Specifies the minimum distance in microns between adjacent pins, or between a pin and a preroute wire that cuts across a block edge in the normal direction. Pins that are created are always snapped to wire tracks. Value must be >= 0. The pin spacing track count default of 1 wire track is used if neither -pin_spacing_track_count nor -pin_spacing_distance is specified. The -pin_spacing_track_count and -pin_spacing_distance options are mutually exclusive.

`-sides` *`side_numbers`*

Specifies a list of block sides where pins must be placed. Each side number must be >= 1. Sides are numbered starting with the leftmost vertical edge (side number 1) of the block and increments by one going clockwise around to each edge of the block. If there are multiple leftmost edges, then the starting edge is the lowest of the leftmost edges. The -sides and -excluded_sides options are mutually exclusive.

`-excluded_sides` *`side_numbers`*

Specifies a list of block sides where pins cannot be placed. Each side number must be >= 1. Sides are numbered starting with the leftmost vertical edge (side number 1) of the block and increments by one going clockwise around to each edge of the block. If there are multiple leftmost edges, then the starting edge is the lowest of the leftmost edges. The -sides and -excluded_sides options are mutually exclusive.

`-allow_feedthroughs`

Indicates that feedthrough ports can be created during pin placement. When feedthrough ports are allowed, global routing creates feedthrough routing on blocks as necessary which alters the netlist. Feedthrough ports are disallowed if this option is not specified, that is, they are not created during pin placement.

`-stacking_type any | none | with_pg_pins_only | with_signal_pins_only`

Specifies how signal pins can be stacked with other pins during pin placement. The default is "any". Valid values are:

any - Signal pins can stack with other signal pins on different layers. Signal pins can also stack with PG straps and pins on different layers.

none - Signal pins cannot stack with other signal pins on different layers. Signal pins cannot stack with PG straps and pins on different layers.

with_pg_pins_only - Signal pins cannot stack with other signal pins on different layers. However signal pins can stack with PG straps and pins on different layers.

Feedback

with_signal_pins_only - Signal pins can stack with other signal pins on different layers. However signal pins cannot stack with PG straps and pins on different layers.

`-width` *`pin_width`*

Specifies the width of the pin. The width is perpendicular to the layer's preferred routing direction. The syntax is either a single width indicating the pin width for all layers, or a list of layer width pairs indicating the pin width for each layer that is, {{layerName0 width0} … {layerNameN widthN}}. Each layer name is a string. Each width is a float. If the width is not specified, pin placement uses the layer default width from the tech file.

`-length` *`pin_length`*

Specifies the length of the pin. The length is parallel to the layer's preferred routing direction. The syntax is either a single length indicating the pin length for all layers, or a list of layer length pairs indicating the pin length for each layer (that is, {{layerName0 length0} … {layerNameN lengthN}}). Each layer name is a string. Each length is a float. If the length is not specified, pin placement derives the pin length from pin width.

`-hard_constraints` *`constraint_types`*

Specifies a list of hard constraint types. Pin placement honors the hard constraints without checking design rules, even if honoring them creates design rule violations. The default is "off". Valid values are:

off - None of the constraints are hard.

spacing - The pin spacing constraint is hard. The spacing between adjacent pins is at least the value specified by the associated spacing constraints.

location - The location constraint is hard. The pins are placed at the exact side and offset specified by the associated pin location constraints. If the location constraint is specified as coordinates through the set_individual_pin_constraints command along with the -off_edge option, the pin is placed at the specified coordinates. However if specified without the -off_edge option, the pin is placed at the snapped edge and offset.

layer - The layer constraint is hard. The pins are placed on the layer specified by the associated layer constraints.

length - The length constraint is hard. The pins have the exact lengths specified by the associated length constraints.

`-cells` *`cell_list`*

Specifies the physical cells where the constraint is to be added. The constraint is created in the reference block of the physical cell. The reference block must

Feedback

not be a library cell and must not already have a block_pin_constraint since each block might have at most one. If side numbers are specified by using the -sides or -excluded_sides option, they must be specified in the current block's coordinate system. During constraint creation, the side numbers are automatically transformed to the reference block's coordinate system if the cell orientation is not R0.

Description

This command creates a new block_pin_constraint in the current block or in each of the specified cells' reference blocks, and returns a collection containing the new block_pin_constraints. The block_pin_constraint contains a set of constraints that are honored during pin placement. These constraints might be queried and modified through the block_pin_constraint attributes.

Examples

The following example creates a block_pin_constraint in the current block with hard location and length constraints.

```
prompt> create_block_pin_constraint -allowed_layers {M1 M2} -sides {1
3} -allow_feedthroughs -stacking_type with_pg_pins_only
-hard_constraints {location length}
```

---

create_bond_pad_array

Creates a bond pad (hybrid bond link) array in the current design.

Syntax

int *create_bond_pad_array*

```
[-layer layer_name]
[-name array_name]
[-width width]
[-height height]
[-bbox { {llx lly} {urx ury} } ]
[-boundary polyrect]
-delta {dx dy}
[-pattern inline | staggered_1 | staggered_2]
[-repeat {columns rows}]
[-origin {x y}]
[-bond_pad_def bond_pad_def_name]
```

Feedback

Data Types

```
layer_name        string
array_name        string
width             float
height            float
llx               float
lly               float
urx               float
ury               float
polyrect          list
dx                float
dy                float
columns           integer
rows              integer
x                 float
y                 float
bond_pad_def_name string
```

Arguments

`-layer` *layer_name*

Specifies the bond pad array layer.

`-name` *array_name*

Specifies the bond pad array name.

`-width` *width*

Specifies the bond pad shape width.

`-height` *height*

Specifies the bond pad shape height.

`-bbox { {`*llx lly*`} {`*urx ury*`} }`

Specifies the region in which to place the bond pad. This option and the *-boundary* option are mutually exclusive. If neither this option nor *-boundary* option is used, the entire design area is used.

`-boundary` *polyrect*

Specifies a *polyrect* region in which to place the bond pad. This option and the *-bbox* option are mutually exclusive. If neither this option nor *-bbox* option is used, the entire design area is used. The *polyrect* is described as a list of location coordinates.

`-delta {`*dx dy*`}`

Specifies the horizontal pitch (*dx*) between adjacent columns and the vertical pitch (*dy*) between adjacent rows. This is a required option.

Feedback

`-pattern inline | staggered_1 | staggered_2`

Specifies the placement pattern of the bond pad. Valid values for this option are: inline, staggered_1, and staggered_2. The inline argument places bond pad at every grid point. The staggered_1 argument places bond pad only at grid points where the sum of column index and row index is even. The staggered_2 argument places bond pad only at grid points where the sum of column index and row index is odd. If this option is not specified, the command creates an inline bond pad array.

`-repeat {`*`columns rows`*`}`

Specifies the total number of columns and rows in the bond pad array. The command does not create bond pad outside of the bond pad array bounding box, even if you specify a column or row count beyond the bounding box. If this option is not specified, the command fills the bounding box or design area with bond pads.

`-origin {`*`x y`*`}`

Specifies the spacing between the lower-left corner of bond pad array bounding box and the lower-left corner of the bounding box of the bond pad located at column 0 and row 0. If this option is not specified, the command derives the origin so that the bond pad array is centered in the bounding box.

`-bond_pad_def` *`bond_pad_def_name`*

Specifies the name of bond pad def. The specified bond pad def will be used to create bond pad. It cannot be used with "-layer", "-width" and "-height".

Description

This command creates an array of bond pads.

Examples

The following example creates an array of bond pads.

```
prompt> create_bond_pad_array -layer AP -width 20 -height 20 \\
   -delta {200 200} -bbox {{350 400} {1350 1400}}
```

---

create_bond_pad_def

Creates a bond pad definition object in the current design.

Syntax

collection *create_bond_pad_def*

```
-name bond_pad_def_name
-layer layer
[-boundary geometry]
[-num_sides sides]
[-dimensions coord]
```

Data Types

terminal_name	string
layer	collection
geometry	list
sides	integer
coord	float_pair

Arguments

`-name bond_pad_def_name`

Specifies the name of bond pad definition to be created. This is a mandatory option.

`-layer layer`

Specifies the tech layer for bond pad. You must specify a single layer using either the layer name from the technology file or a collection containing exactly one layer. This is a mandatory option.

Feedback

`-boundary` *`boundary_spec`*

Specifies the list of points which represent the boundary of the shape to be created for the bond pad, or a pair of points representing it in the form of bounding box. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  `{{`*`llx lly`*`} {`*`urx ury`*`}}`

- Specify a rectilinear boundary by using the following syntax to specify the boundary of the polygon:

  `{{`*`x1 y1`*`} {`*`x2 y2`*`} ... {`*`xn yn`*`}}`

  This is a mandatory option, if *-num_sides* and *-dimensions* options are not specified. This option is mutually exclusive with *-num_sides* and *-dimensions* options.

`-num_sides` *`sides`*

Specifies an integer for number of bond pad sides between 4 to 1024. Value of 4 implies a square, 5 implies a pentagon, and so on. It is assumed that all sides of the shape are of the same length. This is a mandatory option, if *-boundary* option is not specified. This option is mutually exclusive with *-boundary* option. The *-num_sides* option must be specified with *-dimensions* option.

`-dimensions` *`coord`*

Specifies the width and height of the bond pad in user units. It is used along with *-num_sides* to determine the exact shape and size of the bond pad. This is a mandatory option, if *-boundary* option is not specified. This option is mutually exclusive with *-boundary* option. The *-dimensions* option must be specified with *-num_sides* option.

Description

This command creates a bond pad definition in the current block and returns the newly created object, if successful.

The bond pad is a metal polygon with the specified shape on a particular tech layer. In general, a bond_pad_def can be used like a bump cell definition to create the specified bond pad instead of a reference bump cell. The *bond_pad_def_name* must be distinct from any cell definition in the design.

The bond_pad_def attributes cannot be updated after creation.

There are two ways to define a shape either via *-boundary* option or by *-num_sides* and *-dimensions* options. When shape is defined using *-boundary* option the *num_sides* and *dimensions* attributes values will be 0 and {0 0} respectively. However, when shape is

Feedback

defined using *-num_sides* and *-dimensions* option the *boundary* attribute will be calculated using the *num_sides* and *dimensions* attributes.

Examples

The following command creates an bond pad definition using *boundary* option.

```
prompt> create_bond_pad_def -name bond_pad_def_1 -layer L1 -boundary { {0
 0} {1 1}}
```

The following command creates an bond pad definition using *num_sides* and *dimensions* option.

```
prompt> create_bond_pad_def -name bond_pad_def_2 -layer L2 -num_sides 4
 -dimensions {2 2}
```

The following command reports the created bond pad definitions.

```
prompt> report_collection [get_bond_pad_defs ] -columns {name layer
 boundary num_sides dimensions}
```

See Also

---

create_bond_pad_reference

Create a reference bond pad where the bond_pad_ref_name can be used to refer to its physical implementation in current block.

Syntax

status *create_bond_pad_reference*

```
name the name of bond pad reference
-num_sides the number of sides
-dimensions diensions of bond pad bbox
-layer layer
```

Data Types

the number of sides	unsigned
diensions of bond pad bbox	coord
layer	layer
name	string

Feedback

Arguments

`name` *the name of bond pad reference*

Specifies the name of bond pad reference to be created in this design. Each reference name must be unique. This is a required option.

`-num_sides` *the number of sides*

Specifies an integer for number of bond pad sides between 4 to 1024. This is a required option.

`-dimensions` *diensions of bond pad bbox*

Specifies the width and height of the bond pad in micron. This is a required option.

`-layer` *layer*

Specifies layer for bond pad This is a required option.

Description

Create a reference bond pad where the bond_pad_ref_name can be used to refer to its physical implementation. The bond pad is a metal polygon with the specified shape and layer. In general, a bond_pad_ref_name can be used like a bump cell reference to create the specified bond pad instead of a bump cell. The bond_pad_ref_name must be distinct from any cell reference in the design.

Examples

The following example creates a reference of bond pad that name is "hbl_ref", shape is rectangle, dimensions is {30 30} and the layer is M1.

```
prompt> create_bond_pad_reference hbl_ref -num_sides 4 -dimensions {30
 30} -layer M1
```

---

create_bound

Creates a move bound or group bound in the current design.

Syntax

collection *create_bound*

```
-name bound_name
[-boundary regions
[-dimensions bound_dimension]
[-diamond central_object]
[-effort low | medium | high | ultra]
[-type soft | hard]
[-exclusive]
[-macro_group]
```

Feedback

```
[-hierarchical_only]
[-design_type design_type]
[-repelling diamond | rect]
[-cell cell]
[cell_and_port_and_group_list]
[-color color]
```

Data Types

```
bound_name          string
regions             list
bound_dimension     list
central_object      collection
design_type         string
cell                collection
cell_and_port_and_group_list list
color               string
```

Arguments

`-name bound_name`

Specifies the name of the bound.

`-boundary regions`

Creates move bounds with the specified boundaries. You can specify one or more rectangles, polygons, and geometric objects. If you specify more than one placeable area, the coarse placer can place cells in any of the move bound's bound shapes. These placeable areas can overlap or be disjoint.

To specify a rectangle, use the following format to specify the lower-left and upper-right corners of the rectangle:

```
{{llx lly} {urx ury}}
```

To specify a polygon, use the following format to specify the coordinates of the polygon:

```
{{x1 y1} {x2 y2} {x3 y3} ... {xn yn}}
```

Each rectangle and polygon defines a target placement area for the objects. The areas can overlap or be disjoint. The coordinates are relative to the chip origin.

You can also specify polygons as the combined area of a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. For poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. For layers, the resulting area includes the area of every shape in the layer.

This option is mutually exclusive with the *-dimensions* option; you can specify only one.

Feedback

`-dimensions` *`bound_dimension`*

Creates a group bound with the specified dimensions.

For a group bound, specify the dimension as {*width height*}.

For a diamond bound, specify the dimension as {*length*}. When you use this format, you must also specify the *-diamond* option.

This option is mutually exclusive with the *-boundary* option; you can specify only one.

`-diamond` *`central_object`*

Creates a diamond bound centered on the specified object, which can be a port, cell, or pin. You can specify only one object.

The objects in the bound are constrained to lie within the distance specified by the *-dimensions* option (measured as a Manhattan distance) of the specified object. A diamond bound is always a soft bound.

If you specify this option, you must also specify the *-dimensions* option.

`-effort low | medium | high | ultra`

Specifies how strongly a bound works to keep cells within the constraint.

When you set the effort to *ultra* (the default), cells will have limited ability to be placed outside the bound shape. Lower effort levels allow cells to be placed further from the bound. Lowering effort is useful when you want to allow placement flexibility to fix timing, wire length, or congestion. Most large bounds work well with medium effort.

Bounds with *-boundary* or *-dimensions* have a default effort of *ultra*. Otherwise, the default effort is *medium*.

You may not specify *-effort* with the *-diamond*, *-repelling*, *-exclusive*, or *-type hard* options.

`-type soft | hard`

Sets the bound type to be either hard or soft.

The default is *soft*.

When you specify *-type hard*,

- You must also specify the *-boundary* or *-dimensions* option
- You cannot specify the *-effort* option

Feedback

`-exclusive`

Sets the bound to be exclusive. This option is allowed only for move bounds. A move bound that is exclusive requires all of its cells to be placed inside it and prohibits the placement of other cells in the same area. Exclusive move bounds are respected by both coarse placement and legalization.

`-macro_group`

Sets the bound to be macro_group bound. This option is allowed only for move bounds.

This option specifies that the bound can contain only cells whose reference is of *macro* design type.

This option is mutually exclusive with *-exclusive*, *-hierarchical_only* and *-design_type* options.

`-hierarchical_only`

Specifies that the bound can contain only cells that represent module boundary objects, which are created by the *explore_logic_hierarchy* command. This option is allowed only for move bounds. No other cells or ports can be added to move bounds of this type.

This option creates move bounds that are used during floorplanning; the have no effect on other placement or legalization.

`-design_type` *`design_type`*

Specifies that the bound can contain only cells whose reference is of the specified design type. This option is allowed only for move bounds. The valid values for this option are *abstract*, *analog*, *black_box*, *corner*, *cover*, *diode*, *end_cap*, *feedthrough*, *fill*, *filler*, *flip_chip_driver*, *flip_chip_pad*, *lib_cell*, *macro*, *module*, *pad*, *pad_spacer*, and *well_tap*. No other cells or ports can be added to move bounds of this type.

This option creates move bounds that are used during floorplanning; they have no effect on other placement or legalization. The expected usage is to create move bounds that contain only hard macros.

`-repelling diamond | rect`

Specifies that the bound is repelling rather than attractive. Repelling bounds keep the bound contents spread apart by the specified shape region.

`-cell` *`cell`*

Specifies the physical cell in which to add the bound. The bound is created in the cell's reference block using the coordinate system of the cell's top block. The cell must reference a block, not a library cell, unless this command is run in the library manager. In the library manager, bounds can be created in library cells.

Feedback

If you do not specify this option, the bound is created in the current block.

cell_and_port_and_group_list

Specifies the cells, ports, and groups to assign to the bound. The list can contain names, patterns, or collections. Group objects are only valid when creating a repelling bound. Furthermore, repelling bounds may contain either cells and ports or groups, but not a mix.

It is an error to specify a port that has already been assigned to another bound.

If this bound is a move bound, it is an error to specify a cell that has already been explicitly assigned to another move bound.

If this bound is a group bound, it is an error to specify a cell that has already been explicitly assigned to another group bound.

If a cell is hierarchical, its child cells are also implicitly in the bound, as well as any cells added to its hierarchy in the future, unless the child cell is assigned to another bound.

Cells that belong to a relative placement group cannot be individually assigned to a bound. All cells of a relative placement group must be assigned to a bound together.

If you do not specify this argument, the tool creates an empty bound. You can later assign cells and ports to the bound by using the *add_to_bound* command.

-color *color*

Creates a move bound with the specified color, where color is a 24-bit RGB hexadecimal string prefaced by '#', for example: "#72c4f1" or "#ce8322".

Description

This command defines region-based placement constraints for coarse placement. There are two different types of bounds:

- Move bound

  A move bound restricts the placement of cells within fixed regions (bound shapes) of the core area. To create a move bound, specify the absolute coordinates with the *-boundary* option.

- Group bound

Feedback

A group bound restricts the placement of cells within a floating region. Cells are placed within a bound but its absolute coordinates are not fixed, instead they are optimized by the placer.

To specify the floating region size for a group bound, use the *-dimensions* option. If you do not specify the *-dimensions* (or *-boundary*) option, the tool creates an automatic group bound, whose floating region is automatically determined by the placer.

Repelling bounds function like group bounds, but instead of defining an area within which the objects should be placed, they indicate an area of separation that should exist between each pair of objects in the bound.

Generally, there is no guarantee that cells will be placed completely within a bound. For example, coarse placement will violate bounds if the quality of its primary placement objectives would otherwise be degraded. In these situations, you should revisit your and floorplan to ensure that the block is not overconstrained. Alternatively, you can use the *-type hard* option to create a hard bound (the default is soft). The coarse placer tries to honor hard bounds as hard constraints while sacrificing other objectives, such as timing and routability. You should not use many hard bounds because this might result in inferior placement solutions.

To assign cells and ports to an existing bound, use the *add_to_bound* command. To unassign cells and ports from a bound, use the *remove_from_bound* command.

Examples

The following example creates a hard exclusive move bound named "movebound1" with one rectangular and one polygon bound shape. The bound contains the invA1 cell and reset port.

```
prompt> create_bound -name "movebound1" -boundary {{{100 100} {200 200}}
 \\
   {{1000 1000} {2000 1000} {2000 4000} {1500 4000} {1500 2000} {1000
 2000}}} \\
   -type hard -exclusive {invA1 reset}
```

The following example creates a move bound named "movebound2" that contains the hierarchical cell named mid. It also implicitly contains all cells within the mid hierarchical cell.

```
prompt> create_bound -name "movebound2" -boundary {{0 0} {200 200}} \\
   [get_cells mid]
```

The following example creates a move bound named "movebound3" with rectilinear bound shapes that have the same boundaries as the merged areas of voltage_area_shapes whose names start with VA_SHP_.

```
prompt> create_bound -name "movebound3" \\
   -boundary [get_voltage_area_shapes VA_SHP_*]
```

Feedback

The following example creates an automatic group bound named "groupbound1" with ultra effort that contains all physical cells whose names start with adder.

```
prompt> create_bound -name "groupbound1" -effort ultra { adder* }
```

The following example creates a diamond bound named "temp3"centered on the MOD/U1/A pin. The MOD/INST1 and MOD/INST2 cells are constrained to be at most 64 microns of Manhattan distance away from MOD/U1/A.

```
prompt> create_bound -name "temp3" -dimensions 64 \\
   -diamond MOD/U1/A {MOD/INST1 MOD/INST2}
```

The following example creates a macro_group move bound named "macroGroupMovebound".

```
prompt> create_bound -name "macroGroupMovebound" -macro_group -boundary
 {{0 0} {200 200}}
```

- report_bounds

---

create_bound_shape

Creates a bound shape on a move bound.

Syntax

```
collection create_bound_shape
-bound bound_object
-boundary { {llx lly} {urx ury} } |
           { {x y} {x y} {x y} {x y} ... } |
           geometric_objects
```

Feedback

Data Types

bound_object	collection
llx	float
lly	float
urx	float
ury	float
x	float
y	float
geometric_objects	collection

Arguments

`-bound` *bound_object*

The bound on which to create the bound shape.

`-boundary { {`*llx lly*`} {`*urx ury*`} } | {{`*x y*`} {`*x y*`} {`*x y*`} {`*x y*`}...} | geometric_objects`

Specifies the boundary of the bound shape. The boundary may be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates (i.e., {*llx lly*} {*urx ury*}). A polygon is specified by its points (i.e., {*x y*} {*x y*} {*x y*} {*x y*}...).

A polygon may also be specified as the combined area of a heterogenous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

Description

The create_bound_shape command creates a bounding region on a move bound. A move bound may have multiple bound shapes.

This command will not allow bounding region creation on a macro_group move bound. User can create bound shapes on macro_group move bound while creating the bound itself using create_bound.

Examples

```
prompt> create_bound_shape -bound "movebound1" -boundary {{100 100} {200
 200}}
```

Feedback

```
prompt> create_bound_shape -bound "movebound2" -boundary [get_shapes
 RECT_0]
```

---

create_boundary_cells

Creates and places boundary cells into a design.

This command is deprecated and will be obsolete in future release. Use *compile_advanced_boundary_cells command*.

Syntax

status *create_boundary_cells*

```
[-left_boundary_cell lib_cell_name]
[-right_boundary_cell lib_cell_name]
[-bottom_boundary_cells lib_cell_name]
[-top_boundary_cells lib_cell_name]
[-bottom_left_outside_corner_cell lib_cell_name]
[-bottom_right_outside_corner_cell lib_cell_name]
[-top_left_outside_corner_cell lib_cell_name]
[-top_right_outside_corner_cell lib_cell_name]
[-bottom_left_inside_corner_cells lib_cell_name]
[-bottom_right_inside_corner_cells lib_cell_name]
[-top_left_inside_corner_cells lib_cell_name]
[-top_right_inside_corner_cells lib_cell_name]
[-mirror_left_outside_corner_cell]
[-mirror_right_outside_corner_cell]
[-mirror_left_inside_corner_cell]
[-mirror_right_inside_corner_cell]
[-mirror_left_boundary_cell]
[-mirror_right_boundary_cell]
[-mirror_left_inside_horizontal_abutment_cell]
```

Feedback

```
[-mirror_right_inside_horizontal_abutment_cell]
[-tap_distance distance]
[-top_tap_cell lib_cell_name]
[-bottom_tap_cell lib_cell_name]
[-prefix boundary_cell_prefix]
[-separator boundary_cell_separator]
[-insert_into_blocks]
[-at_va_boundary]
[-no_1x]
[-min_row_width width ]
[-add_metal_cut_allowed]
[-do_not_swap_top_and_bottom_inside_corner_cell]
```

Data Types

lib_cell_name	string
distance	float
boundary_cell_prefix	string
boundary_cell_separator	string
width	float

Arguments

`-left_boundary_cell` *lib_cell_name*

Specifies the library cell to be placed at the beginning of each cell row.

`-right_boundary_cell` *lib_cell_name*

Specifies the library cell to be placed at the end of each cell row.

`-bottom_boundary_cells` *lib_cell_name*

Specifies the library cells to be placed along the bottom object boundaries. In a double-back design, adjacent rows are flipped; the bottom boundary cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

`-top_boundary_cells` *lib_cell_name*

Specifies the library cells to be placed along the top of object boundaries. In a double-back design, adjacent rows are flipped; the top boundary cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

`-bottom_left_outside_corner_cell` *lib_cell_name*

Specifies the library cell to be placed at bottom-left outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

Feedback

`-bottom_right_outside_corner_cell` *lib_cell_name*

Specifies the library cell to be placed at bottom-right outside corners. An outside corner is a corner with a 90-degree inside angle. A bottom corner is a corner that is on a bottom boundary. In a double-back design, adjacent rows are flipped; the bottom corner cell is used on unflipped bottom boundary rows and on flipped top boundary rows.

`-top_left_outside_corner_cell` *lib_cell_name*

Specifies the library cell to be placed at top-left outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

`-top_right_outside_corner_cell` *lib_cell_name*

Specifies the library cell to be placed at top-right outside corners. An outside corner is a corner with a 90-degree inside angle. A top corner is a corner that is on a top boundary. In a double-back design, adjacent rows are flipped; the top corner cell is used on unflipped top boundary rows and on flipped bottom boundary rows.

`-bottom_left_inside_corner_cells` *lib_cell_name*

Specifies the library cell to be placed at the bottom-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

`-bottom_right_inside_corner_cells` *lib_cell_name*

Specifies the library cell to be placed at the bottom-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

`-top_left_inside_corner_cells` *lib_cell_name*

Specifies the library cell to be placed at the top-left of inside corners. An inside corner is a corner with a 270-degree inside angle. A left inside corner cell is an inside corner cell on the left end of the horizontal edge that makes up the inside corner.

`-top_right_inside_corner_cells` *lib_cell_name*

Specifies the library cell to be placed at the top-right of inside corners. An inside corner is a corner with a 270-degree inside angle. A right inside corner cell is an inside corner cell on the right end of the horizontal edge that makes up the inside corner.

Feedback

`-mirror_left_outside_corner_cell`

Places left outside corner cells in a mirrored orientation.

`-mirror_right_outside_corner_cell`

Places right outside corner cells in a mirrored orientation.

`-mirror_left_inside_corner_cell`

Places left inside corner cells in a mirrored orientation.

`-mirror_right_inside_corner_cell`

Places right inside corner cells in a mirrored orientation.

`-mirror_left_boundary_cell`

Places left boundary cells in a mirrored orientation.

`-mirror_right_boundary_cell`

Places right boundary cells in a mirrored orientation.

`-mirror_left_inside_horizontal_abutment_cell`

Places left inside horizontal abutment cells in a mirrored orientation.

`-mirror_right_inside_horizontal_abutment_cell`

Places right inside horizontal abutment cells in a mirrored orientation.

`-tap_distance` *`distance`*

Specifies the distance in microns between tap cells.

`-top_tap_cell` *`lib_cell_name`*

Specifies the tap cell to be placed at the top boundary. The tool inserts this tap cell at the specified interval on top boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the top tap cell is used on unflipped top boundary rows and on flipped bottom boundary rows. This option must be used with the *-tap_distance* option.

`-bottom_tap_cell` *`lib_cell_name`*

Specifies the tap cell to be placed at the bottom boundary. The tool inserts this tap cell at the specified interval on bottom boundary rows. This tap cell is for the boundary cells and should not be confused with tap cells for standard cells. In a double-back design, adjacent rows are flipped; the bottom tap cell is used on unflipped bottom boundary rows and on flipped top boundary rows. This option must be used with the *-tap_distance* option.

Feedback

`-prefix` *`boundary_cell_prefix`*

Specifies the prefix for the created boundary cells. By default, no prefix is added. When you use this option, the command uses the following naming convention for created boundary cells:

boundarycell!*prefix*!*library_cell_name*!*number*

By default, no prefix is added and the command uses the following naming convention:

boundarycell!*library_cell_name*!*number*

`-separator` *`boundary_cell_separator`*

Specifies the separator character that is used when composing the instance name of the boundary cell. The boundary cell instance name consists of a prefix, the library reference cell name and an incrementing number. For example, the instance name "boundarycell!MY_CELL!25" has the boundary cell prefix, the MY_CELL library reference cell name, the incrementing number 25, and the boundary cell separator !. This naming convention allows you to do pattern matching selection of the boundary cells.

By default, the separator character is an exclamation mark (!) and the command uses the following naming convention for created boundary cells:

boundarycell![*prefix*!]*library_cell_name*!*number*

`-insert_into_blocks`

Performs boundary cell insertion in the subblocks. By default, the tool performs boundary cell insertion only in the top-level block.

`-at_va_boundary`

Places horizontal boundary cells on both sides of the voltage area boundaries. When you use this option, rows are treated as cut by voltage area boundaries. Therefore, boundary cells are placed on both sides of a voltage area boundary. By default, voltage area boundaries are ignored during boundary cell insertion.

`-no_1x`

Prevents the tool from placing boundary cells on a row when the row length equals two times the corner cell width plus one unit tile width. Note that if the row length equals two times the corner cell width, the tool inserts boundary cells on that row.

This option can be used only when the *-top_right_outside_corner_cell*, *-bottom_right_outside_corner_cell*, *-top_left_outside_corner_cell* and *-bottom_left_outside_corner_cell* options are all specified.

Feedback

`-min_row_width` *width*

Skips rows with a row width that is smaller than the specified width value.

`-add_metal_cut_allowed`

Adds metal cut allowed underneath the standard cell placeable area. Metal cut allowed and forbidden preferred grid extension routing guides are created. Metal cut allowed routing guides cover the area taken up by all the placeable site rows reduced by the vertical and horizontal shrink factor. The vertical shrink factor is expressed as a percentage of the smallest site row height and the default is 50 percent. It can be set using the chipfinishing.metal_cut_allowed_vertical_shrink_factor application option. The horizontal shrink factor is expressed as a percentage of the smallest site row width. It can be set using the chipfinishing.metal_cut_allowed_horizontal_shrink_factor application option. Finally, forbidden preferred grid extension routing guides are created to cover the remaining area up to the boundary.

`-do_not_swap_top_and_bottom_inside_corner_cell`

Prevents swapping of the top and bottom inside-corner cells for flipped rows.

By default, if a top inside-corner cell is on a flipped row, the tool uses a bottom inside-corner cell instead. If a bottom inside-corner cell is on a flipped row, the tool uses a top inside-corner cell instead.

Description

This command adds boundary cells around the boundaries of objects, such as voltage areas, macros, blockages, and the core area.

Examples

The following example creates boundary cells on both the left and the right edges of boundaries.

```
prompt> create_boundary_cells -left_boundary_cell myLib/CellLeft \\
            -right_boundary_cell myLib/CellRight
```

---

create_budget_busplan

Create a busplan to define the timing of budget segments

Syntax

int *create_budget_busplan*

```
[-name name]
[-rule net_estimation_rule]
-from pins_or_ports
-nets nets
[-force]
```

Data Types

```
name               string
net_estimation_rule string
pins_or_ports      collection
nets               collection
```

Arguments

`-name name`

Specify the name of the busplan object. If you do not specify a name, a unique name will be generated automatically.

`-rule net_estimation_rule`

Specify a net estimation rule. The rule must have be declared previously with the *set_net_estimation_rule* command. If you do not define a rule, the "default" rule is used. The rule is used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

`-from pins_or_ports`

Specify the pins or ports where the busplan begins. If you specify ports, they must be input ports. If you specify pins, they must be output pins of budgeted blocks. Budgeted blocks should be declared by using the *-add_blocks* option of the *set_budget_options* command.

Feedback

You must specify one of *-from* and *-nets*.

`-nets` *nets*

Specify a set of nets through which the busplan should pass. The net must be in the direct fanout of a legal bus start point, separated by buffers or inverters. See *-from* option description for a definition of legal bus start points.

You must specify one of *-from* and *-nets*.

`-force`

Create the busplan, even if it crosses another busplan. If you use this option, then some or all of the existing busplans are removed and replaced by the new busplan definition. By default, a busplan is not created in a place where another busplan already crosses.

Description

This command creates a database object called a "busplan", that can be used to define the timing of budget segments. A busplan is a collection of paths through the design that start at top-level ports or block outputs and end at top-level ports or block inputs. The paths can cross multiple levels of hierarchy and can traverse the following circuit elements:

- buffers and inverters
- level shifters
- isolation cells
- flip-flops and latches

Busplans are declared by specifying either *-from* or *-nets* to indicate where the bus starts. If a path containing only the given elements leads to a legal end point, the busplan is created. You can specify many start pins, ports or nets at the same time to form a multibit busplan.

The busplan also has a net_estimation_rule object associated with it, which you set by using the *-rule* option. The net estimation rule object must be previously declared by using the *set_net_estimation_rule* command. The rule will be used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

After creating a busplan, the budgeter can extract budgeted "segments" which lie along the path of the busplan. You can use the *-busplans* option of the *report_budget* command to see these budget segments. Each budget segment will represent a connection between budgeted blocks, or a feedthrough path through a budgeted bloc.

Use the *-busplans* option of the *compute_budget_constraints* to apply the timing of your busplans to your budget. See the example below for details.

Feedback

This command returns 1 on success, 0 otherwise.

Examples

Create a net estimation rule with 0.5 ns_per_mm propagation time. Define 4 bit busplan starting at block1 and ending at block3. Report on the segments along the busplan. (Note that the bus fed through block2.) Apply the calculated delays from the busplan to the budget.

```
prompt> set outpins B1/OUT1[*]
prompt> set_net_estimation_rule fast_rule -parameter ns_per_mm -value 0.5
prompt> create_budget_busplan -name bus1 -rule fast_rule -from $outpins
prompt> report_budget -busplans bus1

Feedback

create_buffer_trees

Builds buffer trees from the specified driver pins or nets

Syntax

status *create_buffer_trees*

```
[-from pin_net_list]
[-incremental]
[-global_route_based]
```

Data Types

```
pin_net_list     list
```

Arguments

`-from pin_net_list`

Specifies the list or collection of driver pins or nets for which the tool will create buffer trees. When the *-from* option is not specified, the *create_buffer_trees* command works on all drivers.

`-incremental`

Enables incremental buffer tree building from the specified drivers. In the default non-incremental mode, any existing buffer tree downstream from the driver is first removed, and the buffer tree is completely rebuilt. In incremental mode, the existing buffer tree is kept, and buffering is only done on the nets directly driven by the specified drivers.

`-global_route_based`

Enables global route based buffer tree building (GRopto). By default, buffer trees are built using virtual route topologies and extraction. With the *-global_route_based* option, first a congestion map update is performed, then the global router is used to derive buffer tree topologies and to calculate net RCs when building the tree.

Description

create_buffer_trees is used to build buffer trees from a specified list of drivers. Those drivers are specified by the *-from* option, and can be given as a list or collection of driver pins or nets. If nets are given, then the driver pins of those nets are used as the buffer tree drivers. *create_buffer_trees* can be run on the full design by omitting the *-from* option, but this is not the recommended use model. If you are doing initial buffer tree building after initial coarse placement of the design, or you want to fully rebuild all buffer trees after an incremental coarse placement, the recommended use model is to call *place_opt -from initial_drc -to initial_drc*.

Feedback

create_buffer_trees is a preroute optimization command, and typically would be used after initial buffer trees are built in the *place_opt initial_drc* step, and sometime before routing is performed on the design with *route_auto*. *create_buffer_trees* does not route the buffer trees, and it does not legalize the placement. If you are working with a routed design, more targeted post-route buffering can be done using the *add_buffer_on_route* command.

Typical use models for *create_buffer_trees* include:

- Custom building specific buffer trees that have unique requirements, like different lib_cells or routing layers.
- Repairing buffers trees that were damaged by manual modifications to the design placement, such as a user Tcl script that tweaks the placement of registers or other categories of standard cells.

By default, *create_buffer_trees* does full buffer tree building downstream of the specified drivers. This includes removal of any existing buffers and inverters, then rebuilding of the full tree. With the *-incremental* option, *create_buffer_trees* will do no removal of existing buffers. It will only buffer the nets directly driven by the specified drivers, and won't trace through any pre-existing downstream buffers during tree building.

By default, *create_buffer_trees* uses the virtual router to derive the routing topologies that guide the buffer insertion, and it also uses the current preroute extraction model to estimate RCs on the nets driven by the inserted buffers (the default preroute extraction model is called RDE, or route-driven estimation). If the *-global_route_based* option is used, then *create_buffer_trees* will instead use the global router for the buffering topologies as well as the RCs on the nets. "GRopto" is a term sometimes used to refer to buffer tree building with global routing information. Those global routes are not kept in the design after buffering, they are discarded. Using the *-global_route_based* option also triggers a global route congestion map update, so that the buffering topologies are fully congestion aware. Note that using this option will increase the runtime of the command. *create_buffer_trees* does not honor the *place_opt.initial_drc.global_route_based* app option which triggers GRopto mode in the *place_opt initial_drc* command -- you muse use the *-global_route_based* option to get equivalent behavior in *create_buffer_trees.* In either virtual route or global route mode, the calculated RCs on the nets are influenced by any min or max layer settings or non-default routing rules applied to the nets driven by the buffer trees.

If you are building multiple buffers trees, runtime is improved by calling *create_buffer_trees* one time with a collection or list of those drivers specified by the *-from* option, rather than calling *create_buffer_trees* multiple times in a roe.

create_buffer_trees honors the *set_lib_cell_purpose* constraints, and will only use buffers and inverters that were made available with the *optimization* purpose. If you change the *set_lib_cell_purpose* constraints later in the flow, it is possible for some buffers on those trees to then be resized to lib_cells from the new *set_lib_cell_purpose* constraints.

create_bump_array

Creates an array of bump cell instances.

Syntax

int *create_bump_array*

```
[-name bump_array_name]
[-lib_cell bump_cell_name]
[-lib_cell_collection lib_cell_list]
[-bbox { {llx lly} {urx ury} } ]
[-boundary polyrect]
[-exclude_regions polyrect_list]
-delta {dx dy}
[-pattern inline | staggered_1 | staggered_2]
[-repeat {columns rows}]
[-origin {x y}]
[-orientation N | W | S | E | FN | FS | FE | FW]
[-non_overlap]
[-ring_depth {count}]
[-origin_spec bl | c]
[-allow_block]
```

Data Types

```
bump_array_name  string
bump_cell_name   string
lib_cell_list    collection of library cells
llx              float
lly              float
urx              float
ury              float
polyrect         list
dx               float
dy               float
columns          integer
rows             integer
x                float
y                float
polyrect_list    collection of polyrect
count            integer
```

Feedback

Arguments

`-name` *`bump_array_name`*

Specifies the bump array name. This name is used to name the bumps within the array. If this option is not used, the array is named default_bump_array_*index*, where *index* is a positive integer. The bump cell instances in the array are named as *bump_array_name*_colIndex_rowIndex, where colIndex and rowIndex are integers that represent the column and row of the bump instance, respectively.

`-lib_cell` *`bump_cell_name`*

Specifies the name of bump library cell. All bump instances in a bump array must have the same library cell. User can specify a simple cell name. The tool will search all libraries for the right lib_cell. User can specify the library name and lib_cell name. The library name must be described first followed by lib_cell name. The two names are separated by *:* or */*. User can also specify the view name. The full name of the lib_cell is described as library_name:cell_name.view_name. User can also use hierarchy delimiters, namely library_name/cell_name/view_name. User must describe library name and cell name if they want to describe view name.

`-lib_cell_collection` *`lib_cell_list`*

Specifies the collection of a library cell using *get_lib_cells* command. User can also use the full name of a bump lib_cell. This option and *-lib_cell* option are mutually exclusive. If user specify multiple library cells, only the first one is used. User must either use this option or *-lib_cell* option.

`-bbox { {`*`llx lly`*`} {`*`urx ury`*`} }`

Specifies the region in which to place the bump cell instances. No bump cell instances or parts of a bump cell instance can extend beyond the specified region. This option and the *-boundary* option are mutually exclusive. If neither this option nor *-boundary* option is used, the entire design area is used.

`-boundary` *`polyrect`*

Specifies a *polyrect* region in which to place the bump cell instances. No bump cell instances or parts of a bump cell instance can extend beyond the specified region. This option and the *-bbox* option are mutually exclusive. If neither this option nor *-bbox* option is used, the entire design area is used. The *polyrect* is described as a list of location coordinates.

`-exclude_regions` *`polyrect_list`*

Specified the excluded boundary regions of the bump array.

Feedback

`-delta {dx dy}`

Specifies the horizontal spacing (*dx*) between adjacent columns and the vertical spacing (*dy*) between adjacent rows. This is a required option.

`-pattern inline | staggered_1 | staggered_2`

Specifies the placement pattern of the bump array. Valid values for this option are: inline, staggered_1, and staggered_2. The inline argument places bump instances at every grid point. The staggered_1 argument places bump instances only at grid points where the sum of column index and row index is even. The staggered_2 argument places bump instances only at grid points where the sum of column index and row index is odd. If this option is not specified, the command creates an inline bump array.

`-repeat {columns rows}`

Specifies the total number of columns and rows in the bump array. The command does not create bump instances outside of the bump array bounding box, even if you specify a column or row count beyond the bounding box. If this option is not specified, the command fills the bounding box or design area with bump cells.

`-origin {x y}`

Specifies the spacing between the lower-left corner of bump array bounding box and the lower-left corner of the bounding box of the bump cell instance located at column 0 and row 0. The bump array bounding box is either specified by *-bbox* option or the bounding box of the shape specified by *-boundary* option. If neither *-bbox* nor *-boundary* is used, the bump array bounding box is the entire die area.

If you do not use *-origin* but you specify the *-repeat* option, the command derives the origin so that the bump array is centered in the bounding box. It is important that user chooses the column or row count of the *-repeat* option small enough so that the bump array can be entirely inside the bump array bounding box. If the column or row count is too large, the calculated origin can be outside of the bump array bounding box when the bump array is centered in the bounding box. The bumps outside of the bump array bounding box will not be created in the design.

If this option is not specified and *-repeat* option is not selected either, the command uses (0,0) as the origin.

`-orientation N | W | S | E | FN | FS | FE | FW`

Specifies the orientation of all bumps in the array. If this option is not specified, the default orientation is N.

Feedback

`-non_overlap`

Only place bumps that do not overlap existing ones.

`-ring_depth {`*`count`*`}`

Specifies the width and height of the ring.

`-origin_spec` *`bl | c`*

Specifies whether origin indicates lower-left or center of the lower-left bump: Values: bl, c. bl: lower-left as origin of lower-left bump. c: center as orign of lower-left bump.

`-allow_block`

Allow block as reference cell.

Description

This command creates an array of bump cell instances.

Examples

The following command creates an array of bump cells named BUMP_PAD, with horizontal and vertical spacing of 200. The bump cells are created within a bounding box of {{350 400} {2350 2400}}.

```
prompt> create_bump_array -lib_cell BUMP_PAD -delta {200 200} -bbox {{350
 400} {2350 2400}}
```

---

create_bump_block

Creates a reference cell of a bump.

Syntax

collection *create_bump_block*

```
[-force]
-dimensions dimensions_list
[-origin coordinate]
-layer layer_name
-port_name port_name
[-library lib_name]
[-num_sides num_sides]
[-coincident_boundary]
```

Feedback

```
[-origin_type bottom_left | center | upper_right]
bump_name
```

Data Types

```
dimensions_list       list
coordinate            list
layer_name            string
port_name             string
lib_name              string
num_sides             integer
bump_name             string
```

Arguments

`-force`

Overwrites the bump if one with the same name already exists in the target library.

`-dimensions` *dimensions_list*

Specifies the width and height of the die block in micron.

`-origin` *coordinate*

Specifies the coordinate of origin, defalut value is (0, 0).

`-layer` *layer_name*

Specifies the layer on which the bump rectangle should be created.

`-port_name` *port_name*

Specifies the port name of the bump.

`-library` *lib_name*

Specifies the target library that contains the process technology of the bump to be created. If not specified, the bump cell is created in the current library.

`-num_sides`

Specifies an integer for number of shape sides between 4 to 1024.

bump_name

Specifies the bump name to be created.

`-coincident_boundary`

The block boundary is coincident with the shape boundary, default it's a recatangle.

Feedback

`-origin_type`

An optional argument to specify the origin point for the block boundary. The default setting is "bottom_left". A value of "bottom_left" aligns the specified boundary such that the lower left corner of the bounding box is at the value of *"-origin"*. A value of "center" aligns the specified boundary such that the central point of the bounding box is at the value of *"-origin"*. A value of "upper_right" aligns the specified boundary such that the upper right corner of the bounding box is at the value of *"-origin"*.

Description

The *create_bump_block* command creates a reference cell of a bump that consists of a rectangle at the specified layer with the given port name. This is for quick exploration flow when no actual bump cell is available in the library. For manufacturing, a bump should be properly designed to meet the manufacturing rules.

Examples

The following example creates a bump named ubump.design in the library top.exp.

```
prompt> create_bump_block ubump -force -dimensions {30 30} -origin {0 0}
 -layer M9 -port_name BUMP -library top.exp
Information: Creating block 'ubump.design' in library 'top.exp'.
 (DES-013)
{top.exp:ubump.design}
```

---

create_bump_cluster

Creates a bump cluster in current design based on given pattern cell design, at given coordinate location, and with specified orientation.

Syntax

int *create_bump_cluster*

```
-pattern_cell pattern_cell_name_or_collection
-coordinates {llx lly}
[-net net_name]
[-cluster_name cluster_name]
[-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90 ]
[-coord_spec  bl | c ]
```

Feedback

```
[-force]
[-lock]
```

Data Types

```
pattern_cell_name_or_collection string or collection
llx                 float
lly                 float
net_name            string
cluster_name        string
```

Arguments

`-pattern_cell` *pattern_cell_name_or_collection*

Specifies the pattern cell to be used for creating bump cluster. If a collection is specified, it must contain exactly one pattern cell. This is a required option.

`-coordinates {`*llx lly*`}`

Specifies the coordinate location for lower left corner of pattern cell to be placed. Note, if orientation is specified, this is the lower left corner after orientation has been applied. This is a required option.

`-net` *net_name*

Specifies the net name to be used for connecting all cells inside bump cluster. If specified net does not exist, a new net is created. Default net name is based on bump cluster name, and is of form: *cluster_name*_net.

`-cluster_name` *cluster_name*

Specifies the name to be used for edit_group containing all cells of bump cluster created by this command. If *cluster_name* is not provided, command generates a unique cluster name of form: bump_cluster_xxx, where xxx is a unique integer suffix.

`-orientation R0 | R90 | R180 | R270 | MY | MXR90 | MX | MYR90`

Specifies the orientation of bump cluster as placed at given {*llx lly*} coordinate location. If this option is not specified, the default orientation is R0.

`-coord_spec bl | c`

Specify the user specified coordinates is for bottom left (bl) or center (c) of the new bump cluster. If this option is not specified, the default coord_spec is bottum left.

`-force`

Specifies that bump cluster should be created even if it overlaps with an existing bump cluster. By default, a bump cluster is not created if it detects an overlap with an existing bump cluster.

Feedback

`-lock`

Specifies that the bump cluster should be locked upon creation. By default, the bump cluster is not locked upon creation.

Description

This command creates a bump cluster in current design based on given pattern cell design, at given coordinate location, and with specified orientation.

Examples

The following example creates a bump cluster.

```
prompt> create_bump_cluster -pattern_cell *:TSV4BUMP81 -coordinates {1000
 1000}
```

---

create_bump_pattern

Creates bumps and matching types for a cluster of pads.

Syntax

int *create_bump_pattern*

```
-file_name pattern_file
-bump_prefix prefix
```

Data Types

```
pattern_file  string
prefix        string
```

Arguments

`-file_name` *pattern_file*

Specifies the name of a text file which describes the bump patterns to be created.

Feedback

`-bump_prefix` *prefix*

Specifies the prefix of bump names. The bump names are created by adding an underscore and integer index at the end of the bump prefix. The default prefix is *default_bump_array*.

Description

This command creates one or multiple bumps for some placed IO pads. It also generates one or multiple matching types for impending bump assignment using command *place_io*.

You must create a text file, called a pattern file, to describe the bumps and matching types to be created by this command. The format of this file is described as follows. Specifically, the following line should be used at the beginning of a pattern file to select the bump reference cell. The string *bump_lib_cell* is a keyword and must be placed at the beginning of the line. The *LIB_CELL_NAME* is the full name of the reference cell, including the library name. If a simple string is used as *LIB_CELL_NAME*, current library is assumed.

```
bump_lib_cell LIB_CELL_NAME
```

The following line should also be used at the beginning of a pattern file to specify the pitch value of bump rows or columns. In particular, *bump_pitch* is a keyword and must be placed at the beginning of the line. The *DISTANCE* is in microns.

```
bump_pitch DISTANCE
```

If the pattern file contains multiple lines which define a bump reference cell or bump pitch, the values later in the file will override the previous values and affect the bumps created afterwards.

Bumps and matching types are created for individual clusters of pads, one cluster at a time. For each pad cluster, which is called an IO group, a single unit of description is used in the pattern file. This unit starts with the keyword *io_group*. There must be a left curly bracket after the keyword *io_group*. The detailed description follows the left curly bracket. The unit ends with a right curly bracket.

```
io_group { ..._detailed_description... }
```

In the detailed description part, you must first describe all pads in the cluster. Each pad name must be placed in a pair of curly brackets by itself. Within the same pair of curly brackets, you can add a string type attribute for the pad. The attribute string is separated from the pad name by one or more white space characters. If no attribute string is given, the attribute of the pad is a single letter *s*. All pad names and their own curly brackets are placed in a linear order. The entire order is placed within a pair of curly brackets as follows.

```
{
{pad1 _string_of_pad1}
{pad2}
}
```

Feedback

All pads must be placed before running the *create_bump_pattern* command. The minimum-size rectangle that covers all pads is called the pad boundary box. If the width of the box is larger than the height, the pads are considered to be placed in rows. If the height of the box is larger than the width, the pads are considered to be placed in columns. If the width is the same as the height, the pads are with no orientation.

Bumps to be created and placed are described in groups. Each group of bumps are aligned along a single line. The orientation of the bump group is defined after the pads are described. Specifically, the line starts with a left curly bracket followed by a keyword *orientation*. The value of orientation follows and can be *row*, *column*, or *perpendicular*. The default value is *perpendicular*, which means that the bump line is perpendicular to the pad placement orientation. Clearly, this value cannot be used if pads have no orientation. The line that defines bump group orientation must end with a right curly bracket. The following line shows an example.

```
{ orientation row }
```

After the orientation of the bump groups is specified, the bump groups are defined. Each bump group is a single line of bumps whose orientation is defined using aforementioned orientation line. To describe a line of bumps, five elements are used, each of which is placed in a pair of curly brackets. The first element is the distance between the center line of bumps and the center of pad boundary box. Negative values are used when the pad boundary box center is above or at the right side of the bump center line. Positive values are used when the pad boundary box center is below or at the left side of the bump center line. A single bump line is divided into two parts by the pad boundary box. The second and third elements are used to describe the part either on the left or below pad boundary box when bumps are placed in a row or column, respectively. The second element is the distance between the center of the rightmost or top bump and the left or bottom boundary edge of the pad boundary box, respectively. If the value is positive, the bump center is on the left side or below the corresponding edge. The value is negative otherwise. The third element is a sequence of strings, each of which represents a unique bump. The first string represents the rightmost or top bump. The order is from right to left or from top to bottom. The fourth and fifth elements are used to describe the part of bumps either on the right side or above pad boundary box when bumps are placed in a row or column, respectively. The fourth element is the distance between the center of the leftmost or bottom bump and the right or top boundary edge of the pad boundary box, respectively. If the value is positive, the bump center is on the right side or above the corresponding edge. The value is negative otherwise. The fifth element is a sequence of strings, each of which represents a unique bump. The first string represents the leftmost or bottom bump. The order is from left to right or from bottom to top.

The two parts of a line of bumps have the same pitch, which is defined by *bump_pitch* line outside of current *io_group* unit. However, you can add a sixth element to define a different pitch value for and only for the current bump line.

Feedback

Multiple lines can be used to describe multiple rows or columns of bumps within an *io_group* unit. The full path name of the first pad in the pad description is used as the name of the IO group. The bump names are created by adding an underscore and integer index at the end of the bump prefix.

Bumps to be created have string attributes. Pads also have string attributes. The bumps and pads with the same attribute string form a single matching type, which is created by the *create_bump_pattern* command. The name of the matching type is created by combining the IO group name, an underscore character, and the string of attribute. However, the hierarchy delimiter / is replaced by an underscore _. The uniquify number is created based on the ratio of bumps and pads in the matching type.

A pattern file can contain comment lines. A comment line starts with a # symbol. In addition, a two-character string // indicates all characters afterwards are comments.

Examples

A sample pattern file is shown below. The second and third elements are empty pairs of curly brackets, indicating that all four bumps are on the right side of the pad boundary box. There is no bump on the left side. *pad1* and *pad2* have an attribute equal to *s*. Three matching types will be created, for *vdd*, *gnd*, and *s*, respectively.

```
bump_lib_cell BUMP
bump_pitch  200
io_group {
{ {pad1} {pad2} {pad3 vdd} {pad4 gnd} }
{ orientation row }
{ {0} {} {} {60} {vdd gnd s s} }
}
```

---

create_bump_region

Creates a bump_region in the current block.

Syntax

collection *create_bump_region*

```
[-name name]
[-boundary boundary_spec]
[-pattern pattern]
[-pattern_anchor region | block]
[-content_type bump | bump_tsv | tsv]
[-is_backside]
```

Feedback

```
[-net_pattern 2d_net_array]
[-port_pattern 2d_port_array]
[-tsv_pattern 2d_tsv_array]
[-orientation orientation]
[-boundary_margin distance_list]
[-pattern_offset distance_list]
[-array_size int_pair]
[-origin coord]
[-destructible_bumps]
[-z_offset int]
```

Data Types

name	string
boundary_spec	float
pattern	collection
2d_net_array	list
2d_port_array	list
2d_tsv_array	list
orientation	string
distance_list	list
int_pair	list
coord	list

Arguments

`-name` *name*

Specifies the name of the bump_region. If unspecified, the command generates a name automatically using the prefix "BUMP_REGION" with a system generated number appended.

`-boundary` *boundary_spec*

Specifies the boundary of the bump_region. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  ```
  {{llx lly} {urx ury}}
  ```

- Specify a rectilinear boundary by using the following syntax to specify the coordinates of the polygon:

  ```
  {{x1 y1} {x2 y2} ... {xn yn}}
  ```

- Specify the boundary as a heterogeneous collection of objects with physical geometry, such as poly_rects, geo_masks, shapes, layers, and other physical objects. In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area includes the areas of each object. In the

Feedback

case of layers, the resulting area includes the area of every shape in the layer.

When specifying the boundary polygon as a collection of physical objects, the resulting area must resolve to a single, connected polygon. It is an error to specify a collection of objects with a combined area that resolves to multiple polygons.

This option is mutually exclusive with the *-array_size* option. One of either the *-boundary* or *-array_size* options is required.

`-pattern` *pattern*

Specifies the bump_region pattern which this bump_region references. This bump_region pattern determines the spacing and shape of the pseudo_bumps of the bump_region.

This option is required, unless there exists a default bump_region pattern in the block, in which case the new bump_region's pattern is set to the default bump_region pattern. The default bump_region pattern have its *is_default* attribute set to true.

`-pattern_anchor region | block`

Specifies whether the pattern's pitch and stagger cycling starts at the lower-left of the bump_region boundary's bounding box (region) or at the block origin (block).

This is an optional option. If unspecified, the default is *region*. This option is disallowed if the bump_region is freeform.

`-content_type bump | bump_tsv | tsv`

Specifies the contents of the bump_region: "bump" specifies pseudo_bumps, "bump_tsv" specifies pseudo_bumps plus accompanying pseudo_tsvs, and "tsv" specifies pseudo_tsvs only.

If "bump_tsv" or "tsv" are specified, then the *-tsv_pattern* option must also be specified unless the bump_region's pattern is freeform.

This is an optional option. If unspecified, the default is *bump*, unless the *-tsv_pattern* option is specified, in which case the content_type defaults to *bump_tsv*.

`-is_backside`

Specifies whether the bump_region is on backside.

`-destructible_bumps`

Specifies that all the pseudo bumps in the created region will be marked as destructible by default.

Feedback

`-net_pattern` *`2d_net_array`*

Specifies the default net assignments of the pseudo_bumps in the bump_region, in the form of a two-dimensional list of nets representing the net pattern to be applied cyclically throughout the region.

If the bump_region's *content_type* is "tsv", then the net pattern is applied to the pseudo_tsvs in the region.

This is an optional option. If unspecified, no nets are assigned to bumps or tsvs by default. This option is disallowed if the bump_region is freeform.

The format of the net pattern is {{*list_of_nets_on_row_0...*} {*list_of_nets_on_row_1...*} ... {*list_of_nets_on_row_n...*}}, which forms a two-dimensional array of net assignments to apply to the pattern of the pseudo_bumps. Each element of the list of nets on a row might be a collection of a net object, a net name, or the empty string ("{}") to indicate no net (a net "hole"). Each inner list of nets and net holes applies to the i'th row, cyclically, and the net assignments for that row cycles through the list.

If the net pattern contains any collections or substitution operators ("[]"), you must use the *list* command to form the lists, otherwise the substitutions is not be processed.

Examples:

A 4x4 pattern of nets:

```
[list [list $net00 $net01] [list $net10 $net11]]
```

A pattern alternating between the net named n1 and no net on every row:

```
{n1 {}}
```

A pattern of net n1 on every bump of every first row, net n2 every second row, and no net every third row:

```
{n1 n2 {}}
```

A pattern where every first row has nets $net00, then $net01, then $net02 repeating, and every second row has $net10 across the entire row:

```
[list [list $net00 $net01 $net02] $net10]
```

`-port_pattern` *`2d_port_array`*

Specifies the default port assignments of the pseudo_bumps in the bump_region, in the form of a two-dimensional list of ports representing the port pattern to be applied cyclically throughout the region.

The format of the port pattern is the same as that of the *-net_pattern* option, except with the ports instead of the nets.

Feedback

This is an optional option. If unspecified, no ports are assigned to bumps by default. This option is disallowed if the bump_region is freeform.

`-tsv_pattern` *`2d_tsv_array`*

Specifies that the bump_region will have pseudo_tsvs. When the bump_region's *content_type* is "bump_tsv", then each pseudo_bump of the bump_region will have an associated pseudo_tsv. When the bump_region's *content_type* is "tsv", then the bump_region will have pseudo_tsvs only.

Each non-hole pseudo_tsv will be associated with a pseudo_tsv_def, which defines the pseudo_tsv's array dimensions (each pseudo_tsv may represent a rectangular array of TSVs), the diameter of the TSVs, the spacing between and around the TSV array, etc.

The option value will specify the default pseudo_tsv_def assignments and offsets, in the form of a two- dimensional list of elements representing the pattern to be applied cyclically throughout the region. The specified pseudo_tsv_defs must be in the same block. The interpretation of the offsets depends on the bump_region's *content_type*: when "bump_tsv", the offset of a pseudo_tsv is from its respective pseudo_bump; when "tsv", the offset is from the assigned pattern-based location, similar to pseudo_bump offsets.

The format of the tsv pattern is the same as that of the *-net_pattern* option, except instead of each non-empty element being a net, it is a 3 element list of the form {*pseudo_tsv_def_name x_offset y_offset*}. That is, each non-empty element specifies that the pseudo_tsv must reference the specified pseudo_tsv_def, and its location must be offset based on the bump_region's *content_type* described above. An empty list element specifies that the pseudo_tsv associated with the pseudo_bump must be a hole, in which case it will have an empty *pseudo_tsv_def* attribute value and x and y offset distances of zero.

Note that in the *content_type* "bump_tsv" case, a pseudo_tsv may be a hole whereas the associated pseudo_bump may not, or vice versa - the is_hole status between the two are independent.

Every non-hole pseudo_tsv must reference a pseudo_tsv_def, so if a pseudo_tsv is currently a hole (with an *is_hole* attribute value of "true"), to change it to a non-hole by setting its *is_hole* attribute to "false" requires first setting its *pseudo_tsv_def* attribute value to a valid pseudo_tsv_def in the same block.

Examples:

Set every pseudo_tsv of the region to reference the pseudo_tsv_def "ptdef", and have zero offset:

```
{{{ptdef 0 0}}}
```

Feedback

Set a 4x4 checkerboard pattern of pseudo_tsvs referencing the pseudo_tsv_def "ptdef" with zero offset, alternating with holes:

```
{{{ptdef 0 0} {}} {{} {ptdef 0 0}}}
```

Set rows of pseudo_tsvs referencing "ptdefl" staggered to the left by one micron, alternating with rows of pseudo_tsvs referencing "ptdefr" staggered to the right by one micron:

```
{{{ptdefl -1 0}} {{ptdefr 1 0}}}
```

Set every pseudo_tsv of the region to be a hole by default:

```
{{{}}}
```

Note that pseudo_tsv_def collections instead of names may be used, in which case the "list" keyword/format must be used - see similar examples in the description of the *-net_pattern* option above.

This option is required when the bump_region's *content_type* is "bump_tsv" or "tsv", and the bump_region is not freeform. This option is disallowed if the bump_region is freeform.

`-orientation` *`orientation`*

Specifies the orientation of the bump_region. Valid values are: R0, R90, R180, R270, MX, MXR90, MY, MYR90.

`-boundary_margin` *`distance_list`*

Specifies the boundary margin of the bump_region. This is the inner margin distance between the bump_region's boundary and the pseudo_bumps contained by the bump_region. The value of this argument can be a distance list of length 1, 2, or 4. If length 1, then that distance is enforced on all sides of the bump_region. If length 2, then the first value is the distance enforced on the left and right of the bump_region, and the second value is the distance enforced on the top and bottom of the bump_region. If length 4, then the values can be the distance enforced on the left, bottom, right, and top of the bump_region, respectively.

This option is disallowed if the bump_region is freeform.

`-pattern_offset` *`distance_list`*

Specifies the pattern offset of the bump_region. The value must be a distance list of length 2, where the first element is the offset in the x-direction, and the second element the offset in the y-direction. This value is useful when the pattern has multiple alternating pitch or stagger values, as it specifies a shift in the pattern position with respect to the region boundary. When the pattern offset is set to a positive value in a particular direction, then the pattern appears as though the region boundary was moved in that positive direction compared to

Feedback

the pattern (even though the boundary coordinates stay the same). Conversely, it appears as though the pattern are shifted by that distance in the opposite direction within the boundary.

This option is disallowed if the bump_region is freeform.

`-array_size` *`int_pair`*

Specifies the desired array size of the bump_region. As an alternative to specifying the geometrical boundary of the new bump_region, this argument allows you to specify the desired pseudo_bump array size of the bump_region. When specified, the system automatically sets the bump_region's boundary to a rectangle with the necessary dimensions for that array size.

This option is mutually exclusive with the *-boundary* option. One of either the *-boundary* or *-array_size* options is required.

This option is disallowed if the bump_region is freeform.

`-origin` *`coord`*

Specifies the origin of the system-generated rectangular boundary when the *-array_size* option is specified.

This is a required option when the *-array_size* option is specified, and disallowed otherwise.

`-z_offset` *`int`*

Specifies the z offset of the bump_region, which corresponds to the z position of the bump_region's contents.

The value cannot be negative.

Description

The *create_bump_region* command creates a new bump_region, an object that defines a geometric area filled with representative bump objects called "pseudo_bumps", which can be committed to actual bumps in the design planning stage. The default shape and layout of the pseudo_bumps are defined by a bump_region pattern object that the bump_region references. You can override the default of certain attributes of individual pseudo_bumps by directly setting the attributes on the pseudo_bump objects. The defaults can be set again on pseudo_bump attributes by using the *remove_attribute* command.

When the boundary of a bump_region is set, a range of pseudo_bumps are implicitly created within the specified boundary, such that a pseudo_bump is within the boundary if its location (center point) lies within or on the edge of the boundary before staggering and any user-specified offsets on individual bumps are applied. Since the bump pattern for the bump_regions is grid-like, the pseudo_bumps are identified by a two-dimensional integer

Feedback

index identifying their column and row within the grid. You can query the pseudo_bumps of region "r" by using the *get_pseudo_bumps* command:

```
get_pseudo_bumps -of_objects [get_bump_regions r]
```

Note that the pseudo_bump index {0 0} follows the lower-left corner of the bump_region boundary's bounding box.

The default of the *net* attribute of a pseudo_bump is not determined by the associated bump_region pattern as other pseudo_bump attributes, rather it is based on the *net_pattern* attribute of the bump_region (set directly using the *-net_pattern* option of the *create_bump_region* command). The default net can be overriden by setting the *net* attribute on the pseudo_bump directly, and reverted to the default value by calling *remove_attribute* command on its *net* attribute.

The pseudo_bump object also has a *net_name* attribute of type string, which is tied directly with its *net* attribute, so setting one also sets the other. Since a collection attribute (in this case, *net*) cannot be set directly with an empty collection, you can set the empty net (a nondefault value) value on the pseudo_bump by setting the *net_name* attribute to the empty string ("{}"), overriding the default net.

Similar edits to the pseudo_bump's *port* attribute can be made, which are initially based on the *-port_pattern* option of the *create_bump_region* command.

Examples

The following example creates a bump_region named "region0" with a rectangular boundary in the current block, which references bump_region_pattern "pattern0", and sets the nets "VSS" and "VDD" on alternating pseudo_bumps in each row:

```
prompt> create_bump_region -name region0 -pattern
 [get_bump_region_pattern pattern0] \\
   -boundary {{0 0} {5.0 6.7}} -net_pattern {{VSS VDD}}
{region0}
```

---

create_bump_region_pattern

Creates a bump region pattern in the current block.

Feedback

Syntax

collection *create_bump_region_pattern*

```
-pitch_x distance_list
-pitch_y distance_list
-bump_radius radius
[-name name]
[-type structured | freeform]
[-default]
[-row_stagger_x distance_list]
[-column_stagger_y distance_list]
[-bump_shape triangle | square | pentagon | hexagon | septagon | octagon
 | circle]
```

Data Types

```
distance_list  list
radius         float
name           string
```

Arguments

`-name name`

Specifies the name of the bump region pattern. If unspecified, the command generates a name automatically using the prefix "BUMP_REGION_PATTERN" with a system-generated number appended.

`-type structured | freeform`

Specifies the type of the bump region pattern.

Structured bump_region_patterns describe a two-dimensional pattern of pseudo_bumps, with a specified pitch and optional staggering. Bump_regions referencing structured bump_region_patterns ("structured bump_regions") contain implicitly created pseudo_bumps matching the specified two-dimensional pattern. Pseudo_bumps cannot be directly created or removed by the user in structured bump_regions.

Freeform bump_region_patterns do not describe any pattern information for pseudo_bumps. Bump_regions referencing freeform bump_region_patterns ("freeform bump_regions") are initialized containing no pseudo_bumps. The user must explicitly create new pseudo_bumps using the *create_pseudo_bump* command.

Note that the type of the bump_region_pattern may not be changed once created, and bump_regions must reference bump_region_patterns of the same type over their lifetime.

If unspecified, the default value is "structured".

Feedback

`-default`

Specifies whether to set the new bump region pattern to be the block's default pattern. The default pattern is implicitly used by the *create_bump_region* command as the bump region's reference pattern when its *-pattern* option is unspecified.

There can be only one default bump region pattern in the block. If a default bump region_pattern already exists when this argument is specified, then the new bump region pattern becomes the default, and the original bump region pattern is no longer the default.

`-pitch_x` *`distance_list`*

Specifies the spacing between subsequent columns of bumps in the bump region pattern, where the i'th distance value is the distance between the i'th and the (i+1)'th columns, cyclically. This is a required option.

This option may not be specified if the *-type* option is set to "freeform".

`-pitch_y` *`distance_list`*

Specifies the spacing between subsequent rows of bumps in the bump region pattern, where the i'th distance value is the distance between the i'th and the (i +1)'th rows, cyclically. This is a required option.

This option may not be specified if the *-type* option is set to "freeform".

`-row_stagger_x` *`distance_list`*

Specifies the x-offset added to bumps in each row. The i'th value in the list applies to the i'th row, cyclically.

This is an optional option. The default is no added x-offset.

This option may not be specified if the *-type* option is set to "freeform".

`-column_stagger_y` *`distance_list`*

Specifies the y-offset added to bumps in each column. The i'th value in the list applies to the i'th column, cyclically.

This is an optional option. The default is no added y-offset.

This option may not be specified if the *-type* option is set to "freeform".

`-bump_shape triangle | square | pentagon | hexagon | septagon | octagon | circle`

Specifies the default boundary shape of the bumps in the bump region pattern.

This is a required option.

Feedback

`-bump_radius` *radius*

Specifies the default boundary radius of the bumps in the bump region pattern.

This is a required option.

Description

This command creates a new bump region pattern, which specifies a patterned layout of bumps, including their spacing, shape, and size. The new bump_region_pattern object can be used as the reference pattern for the bump_region objects.

Examples

The following example creates a bump region pattern in the current block, with square bumps that are 0.2 microns wide, and spaced 1 micron apart from each other, with no stagger:

```
prompt> create_bump_region_pattern -pitch_x {1} -pitch_y {1} \\
   -bump_shape square -bump_radius 0.1
{BUMP_REGION_PATTERN0}
```

The following example creates a bump_region_pattern named "pattern0", with circular bumps on rows staggered 0.1 microns back and forth every row:

```
prompt> create_bump_region_pattern -name pattern0 -pitch_x {1} -pitch_y
 {1} \\
    -row_stagger_x {-0.1 0.1} -bump_shape circle -bump_radius 0.1
{pattern0}
```

---

create_bundle

Creates a new bundle of nets in the design.

Syntax

collection *create_bundle*

```
[-name bundle_name]
[objects]
```

Feedback

Data Types

```
bundle_name  string
objects      objects
```

Arguments

`-name bundle_name`

Specifies a unique name for the bundle. If this option is not specified, the command generates a bundle named BUNDLE_n, where n is the current number of existing bundles plus one.

objects

Specifies the objects to add to the bundle. If this option is not specified, the tool creates an empty bundle. Objects specified can be supernets.

Description

This command creates a new homogeneous bundle of nets or supernets in the current design. If you specify a name for the bundle with the *-name* option, the name must be unique. Use the *remove_bundles* command to delete a bundle.

Examples

The following examples create new bundles in the design.

```
prompt> create_bundle
{BUNDLE_5}
prompt> create_bundle -name my_bundle
{my_bundle}
prompt> create_bundle -name my_bundle_3 [get_nets abc]
{my_bundle_3}
```

See Also

- add_to_bundle
- get_bundles
- remove_bundles
- remove_from_bundle
- report_bundles

---

create_bundles_from_patterns

Groups nets into bundles based on net name and the number of nets in the net group.

Feedback

Syntax

status *create_bundles_from_patterns*

```
[-block block]
[-net_name_prefix prefix]
[-net_order ascending | descending]
[-minimum_nets min]
[-maximum_nets max]
[-no_braces]
[-no_brackets]
[-no_angle_brackets]
[-no_underlines]
[-no_colons]
[-no_parentheses]
[-bundle_grouping]
```

Data Types

```
block   collection
prefix  string
min     integer
max     integer
```

Arguments

`-block` *block*

Specifies the reference block where the bundles are to be created. By default the current block is used.

`-net_name_prefix` *prefix*

Specifies the net name prefix to match when creating bundles. By default, the command creates bundles by matching any unique net group names that contain eight or more bits.

`-net_order` *ascending* | *descending*

Specifies the net sorting order. By default, the order is ascending.

`-minimum_nets` *min*

Specifies the minimum number of nets in a bundle. By default, the tool creates bundles for net groups with eight or more nets.

`-maximum_nets` *max*

Specifies the maximum number of nets in a bundle. By default, there is no limit to the number of nets in a bundle.

`-no_braces`

Ignore net group names that contain braces ({}).

Feedback

`-no_brackets`

Ignore net group names that contain brackets ([]).

`-no_angle_brackets`

Ignore net group names that contain angle brackets (<>).

`-no_underlines`

Ignore net group names that contain underscore characters (_).

`-no_colons`

Ignore net group names that contain colon characters (:).

`-no_parentheses`

Ignore net group names that contain parentheses (()).

`-bundle_grouping`

Enable bundle grouping to enable the command to create bundles of other bundles.

Description

This command groups nets into bundles based on net name and number of bits. You can use this command to quickly create bundles from net groups without specifying individual *create_bundle* commands. Net group names are extracted from the design by the tool, or by specifying the *-net_name_prefix* option. You can also specify the bit ordering in the bundle with the *-net_order* option. The tool extracts the net groups and determines the number of bits in the group. Only net groups with eight or more bits, or groups that meet the group size criteria set with the *-minimum_nets* and *-maximum_nets* options, are made into net bundles.

This command supports net group indexes that contain the following characters:

```
bus[i]
bus{i}
bus<i>
bus(i)
bus_i
bus:i
```

Examples

The following example creates a bundle of signals that begin with "ahbmi" and reports the contents of the bundle.

```
prompt> create_bundles_from_patterns -net_name_prefix ahbmi
Information: There are 1 new bundles defined. (LED-102)
{B_ahbmi}
```

Feedback

```
prompt> report_bundles [get_bundles {B_ahbmi}]
Begin bundle report ..
  Bundle NAME: `B_ahbmi'
  Number of objects in bundle 24
  Bundle Type 'net'
  Objects in bundle
    Position = 0, net ahbmi[0]
    Position = 1, net ahbmi[1]
    Position = 2, net ahbmi[2]
    ...
End bundle report
1
```

---

create_bus_routing_style

Creates an analog constraint group with bus_style intent in the current design.

Syntax

collection *create_bus_routing_style*

```
[constraint_group_name]
-for objects
[-gap distance]
[-shield_placement default | double_interleave | half_interleave |
 interleave | outside]
[-corner_type cross | default | river]
[-valid_layers layer_list]
[-layer_spacings {layer1 spacing1 ...}]
[-layer_widths {layer1 width1 ...}]
[-force]
```

Data Types

```
constraint_group_name  string
objects                string or collection
distance               float
layer_list             list
```

Feedback

```
layer1                  string
spacing1                float
width1                  float
```

Arguments

constraint_group_name

Specifies the name of the constraint group. By default, the command generates a unique constraint group named "bus_style_n", where n is a unique, monotonically increasing integer value.

-for *objects*

Specifies the objects - can be nets, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

-gap *distance*

Specifies the spacing between the outermost bus bits and other shapes in the block. The default is zero.

-shield_placement default | double_interleave | half_interleave | interleave | outside

Specifies the shielding type for the main bus trunk, if needed. Allowed values are *default*, *double_interleave*, *half_interleave*, *interleave* and *outside*. The default is *default*, which uses the value from custom.route.bus_intra_shield_placement.

-corner_type cross | default | river

Specifies the bus corner type. Allowed values are *cross*, *default* and *river*. The default is *default*.

-valid_layers *layers*

Specifies the list of layer names to be used for bus trunk. If specified, layers type is set to range, otherwise it is set to default. When specified the min and max layers are derived from the list.

-layer_spacings {*layer1 spacing1 ...*}

Specifies the spacing of a layer used in trunk routing. This is a list of alternating layers and spacings, for example, {M1 5.0 M2 6.0}.

-layer_widths *list*

Specifies the width of a layer used in trunk routing. This is a list of alternating layers and widths, for example, {M1 5.0 M2 6.0}.

Feedback

`-force`

Forces the deletion of an existing constraint group if the name matches the specified *constraint_group_name*. The default is false, and the command exits with an error if the name already exists.

Description

The *create_bus_routing_style* command creates a constraint group for a collection of nets, bundles, and topology_edges with bus_style intent. The constraint is used by Custom Router.

You can specify the valid set of layers for trunk routing, layer-specific spacings and widths. The shielding placement of bus trunk can also be specified.

Examples

The following example creates a constraint group with system generated name "bus_style_1" for nets matching pattern "pr*" which will be of bus_style intent. The shield placement is interleave. Also a spacing of 3 will be used for layer M2 and spacing of 5 will be used for layer M3. The 'pr*' nets are routed with Custom Router.

```
prompt> create_bus_routing_style -for pr* -shield_placement interleave \\
-layer_spacings {M2 3 M3 5}
{bus_style_1}
```

---

create_busplans

Creates one or more busplan objects. Busplan objects are used during bus planning.

Syntax

int *create_busplans*

```
[-name name]
[-rule net_estimation_rule]
[-auto]
[-from pins_or_ports]
[-to pins_or_ports]
[-nets nets]
[-force]
[-add_start_end_cells cells]
```

Feedback

```
[-verbose]
[-reset]
```

Data Types

```
name                string
net_estimation_rule       string
pins_or_ports       collection
nets                collection
cells               collection
```

Arguments

`-name` *name*

Specify the name of the busplan object. If you do not specify a name, a unique name of the form bus* will be generated automatically.

`-rule` *net_estimation_rule*

Specify a net_estimation_rule, which must be previously declared by using the *set_net_estimation_rule* command. If you do not define a rule, the "default" rule is used. The rule is used when calculating the delay of segments in the budget. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

`-auto`

Specify that the tool should automatically find buses in the design. You must specify one of *-auto*, *-from* or *-nets*.

`-from` *pins_or_ports*

Specify where the busplan should begin. If you specify ports, they must be input ports. If you specify pins, they must be output pins of blocks.

You must specify one of *-auto*, *-from* or *-nets*.

`-to` *pins_or_ports*

Specify where the busplan should end. If you specify ports, they must be output ports. If you specify pins, they must be input pins of blocks.

`-nets` *nets*

Specify a set of nets through which the busplan should pass. The net must be in the direct fanout of a legal bus startpoint, separated only by buffers or inverters. See the documentation of the *-from* option for a definition of legal bus start points.

You must specify one of *-auto*, *-from* or *-nets*.

Feedback

`-force`

Create the busplan, even if it crosses another busplan. If you use this option, then some or all of the existing busplans are removed and replaced by the new busplan definition. By default, a busplan will not be defined in a place where another busplan already exists.

`-add_start_end_cells` *cells*

Specifies to add to the list of cell instances where buses can start or end. By default it will contain all top level hard macros and blocks. This information is stored by the command, you do not need to use *-add_start_end_cells* on the next command invocation.

`-verbose`

Output more information when running.

`-reset`

Remove all busplan information from design.

Description

This command creates a database object called a "busplan", that can be used to do register planning. A busplan is a collection of paths through the design that start at top-level ports or block outputs and end at top-level ports, or block inputs. The paths may cross through multiple levels of hierarchy and may also traverse through the following circuit elements:

- buffers and inverters
- level shifters
- isolation cells
- flip-flops and latches

Busplans are declared by specifying either *-from* or *-nets* to indicate where the bus starts or the tool can automatically find and create busplans using *-auto*. You can specify many start pins, ports or nets at the same time, to form a multibit busplan.

The busplan also has a net_estimation_rule object associated with it, which you set by using the *-rule* option. The net_estimation_rule object must have been previously declared by using the *set_net_estimation_rule* command. The rule will be used when calculating the delay of segments in the busplan. In particular, the "ns_per_mm" parameter of the rule will be multiplied by the physical length of the segment to get a delay value.

This command returns 1 on success, 0 otherwise.

Feedback

Examples

Create a net estimation rule with 0.5 ns_per_mm propagation time. Define 8 bit busplan starting at block B1 and ending at block B2. Report on the segments along the busplan.

```
prompt> set_net_estimation_rule fast_rule -parameter ns_per_mm -value 0.5
prompt> create_busplans -name bus1 -rule fast_rule -from B1/OUT1[*] -to
 B2/IN1[*]
prompt> report_busplans -start_end_cells bus1

---

create_cap_cell_rule

Creates a cap cell rule object.

Syntax

collection *create_cap_cell_rule*

```
-name cap_cell_rule_name
-type cap_cell_rule_type
[-design design]
[-min value]
[-max value]
```

Data Types

```
cap_cell_rule_name      string
cap_cell_rule_type      string
```

Feedback

design	collection
value	float or integer

Arguments

`-name` *cap_cell_rule_name*

Specifies the name of cap cell rule to be created. The name must be a unique name. This is a mandatory option.

`-type` *cap_cell_rule_type*

Specifies the cap cell rule type. Valid values are *cap_width*, *capp_height*, *cap_ratio*, *cap_distance*, *cap_spacing*, *tsv_spacing*, *cap_area* and *cap_void_area*. This is a mandatory option.

`-design` *design*

Specifies the design in which to create the cap cell rule. If no design is specified, the cap cell rule is created in the current design. This is an optional option.

`-min` *value*

Specifies the minimum value of cap cell rule of types cap_width, cap_height, cap_spacing, tsv_spacing, cap_area, cap_void_area. This is an optional option. At least one of *-min* or *-max* must be specified.

`-max` *value*

Specifies the maximum value of cap cell rules of types cap_width, cap_height, cap_ratio, cap_distance, cap_area. This is an optional option. At least one of *-min* or *-max* must be specified.

Description

This command creates a cap cell rule object based on the give parameters and returns the newly created object, if successful. This command supports undo or redo operations. The command shows error, if valid value for *cap_cell_rule_type* is not provided. The command shows error, if the *min* or *max* value is not valid. If *-min* and *-max* are both specified, the min value cannot be greater than that of the max value.

Examples

The following command creates a 'cap_width' type cap cell rule.

```
prompt> create_cap_cell_rule -name cap_cell_rule_1 -type cap_width \\
      -min 1.4 -max 5
```

Feedback

---

create_cap_cells

Creates embedded deep trench capacitor (eDTC) cells in a 3D-IC design. Given a design and library cells, this command generates and places DTC cells according to the specified placement scenario and design rules.

Syntax

status *create_cap_cells*

```
-cap cap_lib_cell_name
-vdd vdd_lib_cell_name
-vss vss_lib_cell_name
-filler filler_lib_cell_name
[-scenario scenario_type]
[-orientation orient]
[-rules rule_list]
[-bbox bbox]
```

Data Types

cap_lib_cell_name	string
vdd_lib_cell_name	string
vss_lib_cell_name	string
filler_lib_cell_name	string
scenario_type	string
orient	orientation
rule_list	list
bbox	bounding box

Arguments

`-cap cap_lib_cell_name`

Specify the library cell name for the capacitor cells. This is a required option that defines the capacitor cell design to be placed in the DTC structure.

`-vdd vdd_lib_cell_name`

Specify the library cell name for the VDD cells. This is a required option that defines the VDD cell design to be used in the DTC power grid structure.

Feedback

`-vss vss_lib_cell_name`

Specify the library cell name for the VSS cells. This is a required option that defines the VSS cell design to be used in the DTC power grid structure.

`-filler filler_lib_cell_name`

Specify the library cell name for the filler cells. This is a required option that defines the filler cell design to be used to complete the DTC structure.

`-scenario scenario_type`

Specify the placement scenario for DTC cell insertion. Valid values are:

- "*grid*" : Grid-based placement pattern (default).
- "*fishbone*" : Fishbone placement pattern for optimized power delivery.

`-orientation orient`

Specify the orientation of the DTC cells during placement. Valid orientations include R0, R90, R180, R270, MX, MY, MXR90, MYR90. Default orientation is R0 (no rotation).

`-rules rule_list`

Specify a list of capacitor cell rules that govern the DTC placement. By default, all cap cell rules within the current block will be used. The rule_list should contain cap_cell_rule objects that define constraints such as spacing, area, and continuity requirements.

`-bbox bbox`

Specify the bounding box region for DTC cell insertion. By default, the entire block boundary will be used as the placement region. The bbox should be specified as {{x1 y1} {x2 y2}} coordinates.

Description

The *create_cap_cells* command creates and places eDTC cells in 3D-IC designs. The command implements intelligent placement algorithms to optimize power delivery and meet design rule constraints.

Feedback

Placement Scenarios

The command supports two placement scenarios:

- "*Grid Scenario*:" Places DTC cells in a regular grid pattern across the specified region. This scenario provides uniform distribution and is suitable for designs requiring consistent power delivery density.
- "*Fishbone Scenario*:" Places DTC cells in a fishbone pattern optimized for power delivery efficiency. This scenario considers TSV (Through-Silicon Via) locations and power grid requirements to create an optimized placement that minimizes resistance and improves power integrity.

Cell Placement Process

The command performs the following operations:

- *Library Cell Validation*: Verifies that all specified library cells (capacitor, VDD, VSS, filler) exist and are properly defined.
- *Rule Processing*: Analyzes cap cell rules to extract constraints
- *Region Analysis*: Examines the placement region to identify: existing placement blockages, TSV locations, M1 PG stripes
- *Cell Placement*: Executes the selected placement scenario
- *Rule Compliance*: Ensures all placed cells meet design rule requirements including spacing, area, and continuity constraints.

  The command creates cell instances in the current design block and generates appropriate naming for easy identification and management.

Examples

Create DTC cells using grid placement scenario:

```
prompt> create_cap_cells -cap my_cap_cell -vdd my_vdd_cell -vss
 my_vss_cell -filler my_filler_cell
```

Create DTC cells with fishbone placement in a specific region:

```
prompt> create_cap_cells -cap cap_lib -vdd vdd_lib -vss vss_lib -filler
 fill_lib -scenario fishbone -bbox {{0 0} {1000 1000}}
```

Create DTC cells with specific orientation and rules:

```
prompt> create_cap_cells -cap cap_cell -vdd vdd_cell -vss vss_cell
 -filler filler_cell -orientation R90 -rules {rule1 rule2}
```

Feedback

Create DTC cells with all available options:

```
prompt> create_cap_cells -cap my_cap -vdd my_vdd -vss my_vss -filler
 my_filler \\
        -scenario fishbone -orientation MX -rules {area_rule
 spacing_rule} \\
        -bbox {{100 100} {900 900}}
```

Returns

Returns *OK* if the DTC cell creation completes successfully. Returns *Error* if there are issues with command arguments, missing library cells, placement failures, or other errors that prevent successful completion.

NOTES

```
If cap cell rules exist in the design block, the command will use the
 reference
cells defined in those rules as defaults. If no rules are present,
 default rule setting will be considered.

The command requires a valid current design block and will fail if no
 block is
available or if the specified library cells cannot be found in the
 current library.

The fishbone scenario provides better power delivery optimization but may
 require
longer runtime for complex designs. Grid scenario offers faster execution
 with
uniform distribution.

The command is undoable, allowing you to revert the DTC cell creation if
 needed.
Created cells follow a systematic naming convention for easy
 identification and
subsequent operations.
```

---

create_case_statement

Creates 1 RTL case statement.

Syntax

collection *create_case_statement*

Feedback

```
-expression expression
[-type type]
[-module module | -cell cell]
[-scope scope]
```

Data Types

```
expression          collection
type                string
module              collection
cell                collection
scope               collection
```

Arguments

`-expression expression`

Specifies the RTL statement expression statement for the case statement. The expression type can be ports, nets, bus ports, bus nets, literals, expressions, variables, functions, or lists.

`-type type`

Specifies the type of the case block. The default type is std_case. The available values are std_case, inside_case, casex_case, and casez_case.

`-module module`

Specifies the module to create the case statement in. This option is mutually exclusive with the *-cell* option.

`-cell cell`

Specifies the cell to create the case statement in. This option is mutually exclusive with the *-module* option.

`-scope scope`

Adds the newly created case statement in the scope provided by the RTL statement.

Description

This command creates an RTL case statement. The case statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the case statement is created in the current instance.

Examples

The following example creates 1 case statement in the current instance with the net type expression *u1/u1/xy[1]*.

```
prompt> create_case_statement -expression [get_nets u1/u1/xy[1]] \\
   {"RTL_CASE_1"}
```

Feedback

See Also

- get_statements
- remove_statements

---

create_cell

Creates one or more cells referencing a library cell, module, or via_def

Syntax

collection *create_cell*

```
[-design design]
cell_names
reference
```

Data Types

```
design     collection
cell_names list
reference  collection
```

Arguments

`-design design`

Specifies the design in which to create the cells. If no design is specified, the cells are created in the current design.

cell_names

Specifies the names of the cells to be created in the design. Each cell name must be unique.

reference

Specifies the name of the library cell or module the created cells should instantiate, the reference must already exist.

The reference may also be a via_def when creating through-silicon via ("TSV") cells, in which case the via_def must be of type "through_silicon_via_def". TSV cells, which are identified by their *is_tsv* attribute being true, are created by this command if the reference is either a TSV via_def or a design with design_type "tsv". If a TSV design, it must meet certain criteria, which as of this writing are:

```
- Its design_type attribute must be "tsv",
- It must have exactly one port with two terminals,
- Its boundary attribute must be set.
```

Feedback

Description

This command creates new cells in the current design (unless otherwise specified by -design). One cell is created for each of the names listed.

Examples

The following example creates three instances of the library cell *mylib/ND2*.

```
prompt> create_cell {U23 U1/U24 U2/U7/U25} myLib/ND2
{U23 U1/U24 U2/U7/U25}
```

The following example creates three instances of the library cell *ND2*. It will work similer to **/ND2*

```
prompt> create_cell {U23 U1/U24 U2/U7/U25} ND2
{U23 U1/U24 U2/U7/U25}
```

The following example creates two instances of the module MID.

```
prompt> create_cell {U110 U111} [get_modules MID]
{U110 U111}
```

The following example creates an instance of the lib cell myLib/ND4 using *get_blocks* to find the reference. *get_blocks -all* is needed if the lib_cell is not open already.

```
prompt> create_cell U210 [get_blocks -all myLib:ND4.design]
{U110 U111}
```

---

create_cell_array

Inserts cells in the block in an array style.

Feedback

Syntax

status *create_cell_array*

```
-lib_cell lib_cell
[-voltage_area voltage_area]
[-boundary polygon]
[-x_pitch distance]
[-y_pitch distance]
[-x_offset distance]
[-y_offset distance]
[-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90]
[-checkerboard even | odd]
[-snap_to_site_row true | false]
[-preserve_boundary_row_lib_cells lib_cell_list]
[-prefix prefix]
```

Data Types

lib_cell	string
voltage_area	collection
polygon	list
distance	float
lib_cell_list	collection
prefix	string

Arguments

`-lib_cell` *lib_cell*

Specifies the library cell to insert. You must specify a single library cell. This is a required option.

`-voltage_area` *voltage_area*

Specifies the voltage area in which to insert the cells.

If you do not specify this option or the *-boundary* option, the insertion region is the core area.

If you specify both the *-voltage_area* and *-boundary* options, the insertion region is the overlapping region between the specified voltage area and polygon.

`-boundary` *polygon*

Specifies the region in which to insert the cells.

If you do not specify this option or the *-voltage_area* option, the insertion region is the core area.

If you specify both the *-voltage_area* and *-boundary* options, the insertion region is the overlapping region between the specified voltage area and polygon.

Feedback

`-x_pitch` *distance*

Specifies the horizontal distance between the centers of two cells.

If you do not specify this option, the command inserts a single column of cells whose spacing is specified by the *-y_pitch* option.

If you do not specify this option or the *-y_pitch* option, the command inserts a single cell at the specified offset location.

`-y_pitch` *distance*

Specifies the vertical distance between the centers of two cells.

If you do not specify this option, the command inserts a single row of cells whose spacing is specified by the *-x_pitch* option.

If you do not specify this option or the *-x_pitch* option, the command inserts a single cell at the specified offset location.

`-x_offset` *distance*

Specifies the horizontal offset from the insertion region boundary.

The default is 0.

`-y_offset` *distance*

Specifies the vertical offset from the insertion region boundary.

The default is 0.

`-orient R0|R90|R180|R270|MX|MY|MXR90|MYR90`

Specifies the orientation of the inserted cells. Valid values are *R0*, *R90*, *R180*, *R270*, *MX*, *MY*, *MXR90*, and *MYR90*.

If you do not specify this option, the default orientation depends on the setting of the *-snap_to_site_row* option.

- If *true*, the default orientation is the same as the site row orientation.
- If *false*, the default orientation is *R0*.

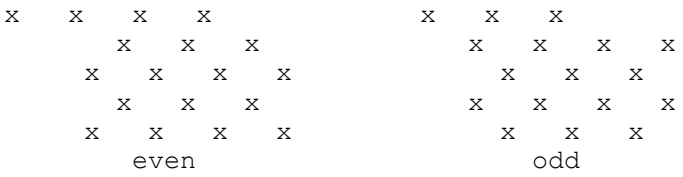
`-checkerboard even | odd`

Inserts cells in a checkerboard fashion. There are two types of checkerboard: *even* or *odd*.

- The even checkerboard type specifies that the first cell is placed at the lower-left corner of the insertion region.
- The odd checkerboard type specifies that a blank space is placed at the lower-left corner of the insertion region.

Feedback

The following figure shows the checkerboard insertion patterns:



If you do not specify this option, the command inserts the cells as a normal array.

`-snap_to_site_row true | false`

Specifies if the new cells are snapped to site rows.

The default is *true*.

`-preserve_boundary_row_lib_cells` *`lib_cell_list`*

Specifies the library cells, such as critical area breaker cells or boundary cells, that require an abutting tap cell. If an empty space in the checkerboard pattern occurs above or below an instance of one of the specified library cells, the command inserts a tap cell in that empty space.

This option is valid only when used with the *-checkerboard* option.

`-prefix` *`prefix`*

Specifies the prefix added to the inserted cell names.

When you use this option, the command uses the following naming convention for the inserted cells:

`<prefix>__<lib_cell>_R#_C#_number`

By default, no prefix is added and the tool uses the following naming convention for the inserted cells:

`headerfooter__<lib_cell>_R#_C#_number`

Description

The *create_cell_array* command inserts an array of cells into the block.

To insert power-switch cells, use the *create_power_switch_array* command instead of this command.

Examples

The following example inserts an array of HEAD_16DM cells in the current block.

Feedback

```
prompt> create_cell_array -lib_cell HEAD_16DM \\
   -x_pitch 10 -y_pitch 10
Insert 684 cell HEAD16DM successfully.
```

See Also

- create_power_switch_array
- create_tap_cells

---

create_cell_array_pattern

Creates a cell array pattern in the current or specified block.

Syntax

collection *create_cell_array_pattern*

```
[-name name]
[-cell cell]
[-type solid | checkerboard]
[-lib_cell_name name]
[-row_column_ratio ratio]
[-horizontal_spacing spacing]
[-vertical_spacing spacing]
[-halo factor]
```

Data Types

name	string
cell	collection
ratio	int_pair
spacing	integer
factor	float

Arguments

`-name` *name*

Specifies the name of the cell_array_pattern. The name may not contain the special characters '~' or '/'. If unspecified, the command will generate a name automatically using the prefix "CELL_ARRAY_PATTERN" with a system-generated number appended.

`-cell` *cell*

Specifies that this cell_array_pattern should be created in the block referenced by *cell*.

Feedback

`-type solid | checkerboard`

Specifies the type of the cell_array_pattern. "solid" means that an instance of the lib_cell should be in every eligible site within the pattern. "checkerboard" means that an instance of the lib_cell should be in every other eligible site along each row, with the rows staggered such that an instance of the lib_cell is in every other eligible site along the columns as well.

`-lib_cell_name` *`name`*

Specifies the name of the lib_cell to be instantiated within the pattern.

`-row_column_ratio` *`ratio`*

Specifies the ratio of rows to columns in the cell_array_pattern. The ratio is an integer pair, with each integer >= 1. Note that the actual number of rows and columns can be any positive integer multiple of these values.

`-horizontal_spacing` *`spacing`*

Specifies the number of sites along each row of the cell_array_pattern between each eligible site for lib_cell placement within the pattern.

`-vertical_spacing` *`spacing`*

Specifies the number of sites along each column of the cell_array_pattern between each eligible site for lib_cell placement within the pattern.

`-halo` *`factor`*

Specifies the halo of the cell_array_pattern. The *factor* is the multiplier of the cell_array_patterns width and height, which indicates the width of the halo in the respective horizontal and vertical directions.

Description

The *create_cell_array_pattern* command creates a new cell_array_pattern in the current block, or the block specified by the *-cell* argument. A cell_array_pattern stores a description of how to place lib_cells associated with topological objects during the interconnect planning phase.

The name of a cell_array_pattern must be unique within its block.

Here is an illustration of two types of cell_array_patterns, each with row_column_ratio of {2 3} and horizontal and vertical spacing of 1:

type = solid, number of rows = 2

[*][ ][*][ ][*] [ ][ ][ ][ ][ ] [*][ ][*][ ][*]

type = checkerboard, number of rows = 4

Feedback

[*][ ][ ][ ][*][ ][ ][ ][*][ ][ ] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [ ][ ][*][ ][ ][ ][*][ ][ ][ ][*] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [*]
[ ][ ][ ][*][ ][ ][ ][*][ ][ ] [ ][ ][ ][ ][ ][ ][ ][ ][ ][ ][ ] [ ][ ][*][ ][ ][ ][*][ ][ ][ ][*]

Examples

The following example creates a cell_array_pattern in the current block:

```
prompt> create_cell_array_pattern
{CELL_ARRAY_PATTERN0}
```

The following example creates a cell_array_pattern with name "mycap", type "checkerboard", row/column ratio of 2/3, and a halo that is 10% of the dimensions of the pattern:

```
prompt> create_cell_array_pattern -name mycap -type checkerboard
 -row_column_ratio {2 3} -halo 0.1
{mycap}
```

See Also

- get_cell_array_patterns
- remove_cell_array_patterns
- report_cell_array_patterns

---

create_cell_bus

Creates one cell bus and it cell members referencing a library cell or module.

Syntax

collection *create_cell_bus*

```
[-design design]
[-create_cells]
[-block block]
[-cell cell]
-reference module
cell_names
```

Data Types

```
design          collection
block           collection
cell            collection
cell_bus_name    string
```

Feedback

Arguments

`-design` *design*

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

`-create_cells`

Creates cell bus members if they do not exist.

`-block` *block*

Specifies the block where the cell bus is to be added. If specified, *create_cell_bus* has the same effect as *edit_module* in which the module is changed and changes are applied to all module occurrences.

`-cell` *cell*

Specifies the cell where the cell bus is to be added. The cell bus is created on the cell's reference module. *create_cell_bus* first uniquifies the reference if needed, then creates the cell bus. When not specified, the cell bus is created on the current module.

`-reference` *module*

Specifies the name of the library cell or module the created cell_bus's member should instantiate, the reference must already exist.

cell_bus_name

Specifies the cell bus name and its range using the *name [start: end]* format. Specify a cell bus named busA with cell from 1 *to* 5 as *busA[1:5]*. Specify a cell bus named busB with cell from 5 *downto* as *busB [5:1]*.

Description

This command creates a cell bus, collects or creates cell bus members, and puts them into the cell bus created.

The command returns the created cell_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

Examples

The following example creates cell bus named *bus1* from cell 1 to 5 as bus[1], bus[2], bus[3], bus[4], bus[5] whose reference is RISC_CORE.

```
prompt> create_cell_bus -reference RISC_CORE bus1[1:5]
{"bus1"}
```

Feedback

The following example first creates cells with reference as RISC_CORE, then creates a cell bus named *bus2* from the created cell with indexes 5 downto 1 as bus2[5], bus2[4], bus2[3], bus2[2], bus2[1]

```
prompt> create_cell_bus -reference RISC_CORE bus2[5:1] -create_cells
{"bus2"}
```

See Also

- get_cell_buses
- remove_cell_buses

---

create_channel_congestion_map

Creates a congestion map for the channel areas of the design.

Syntax

```
int create_channel_congestion_map
[-channel_width_threshold threshold]
[-boundary coordinates]
[-congestion_map_only true | false]
```

Data Types

threshold	float
coordinates	list

Arguments

`-channel_width_threshold` *threshold*

Specifies the threshold for the channel width in microns. Only areas with a width less than or equal to the threshold are considered a channel. By default, if you omit both the *-channel_width_threshold* and *-boundary* options, the tool defines the channel width as 10% of the longest chip dimension and generates a congestion map for the entire design.

`-congestion_map_only true | false`

Creates the congestion map without creating global route segments (glinks). By default, this option is false and the command generates glinks. If design has existing glinks, the command will not remove them if this option is true and the new congestion map could potentially be out of sync comparing with the existing glinks.

Feedback

`-boundary` *coordinates*

Specifies the area in which to generate the considered map. The areas are boundaries specified by a list of rectangles or polygons, with units in microns. Specify the coordinates by using one of the following formats:

```
-boundary {{llx lly} {urx ury}}
-boundary {{x1 y1} {x2 y2} {x3 y3} ...}
```

In the first format, *llx* and *lly* specify the lower-left x- and y-coordinates, and *urx* and *ury* specify the upper-right x- and y-coordinates. In the second format, you specify each corner on the polygon to define the boundary.

When used together with *-channel_width_threshold* option, the command routes channel areas defined by either the *-channel_width_threshold* or *-boundary* options. By default, if you omit both *-channel_width_threshold* and *-boundary* options, the tool defines the channel width as 10% of the longest chip dimension and generates a congestion map for those channels in the entire design.

Description

This command creates a global route-based congestion map for the specified channel or boundary areas. An area is considered a channel if it is enclosed by macro cell boundaries, die boundaries, or block boundaries.

Since this command uses global routing to generate a congestion map, it is possible that congestion might appear in areas outside of the channel areas.

Since this command uses fast, very low effort global routing and other simplifying assumptions to generate a congestion map quickly, it will produce results that are more pessimistic than a congestion map generated by the *route_global -floorplan true* command. Similarly, the results from the *route_global -floorplan true* command will be slightly more pessimistic than results from *route_global*, because *route_global -floorplan true* performs fast, lower effort global routing along with simplifying assumptions to complete global routing quickly.

This command returns 1 on success, 0 otherwise.

Examples

The following example creates a channel congestion map for channel areas with a width less than 10 microns.

```
prompt> create_channel_congestion_map -channel_width_threshold 10
```

Feedback

create_check_design_strategy

Defines checks which can be run through *check_design* command.

Syntax

status *create_check_design_strategy*

```
[-define_check atomic_check_name]
[-define_group mega_check_name]
definition
```

Data Types

```
atomic_check_name          string
mega_check_name            string
definition   list
```

Arguments

`-define_check atomic_check_name`

Specifies the name of the atomic check to create. See *check_design* for definition of atomic-check.

If the specified name is the name of a predefined check (built-in check), the command issues an error message.

If the specified name is the name of an existing user-defined check, the new definition overwrites the previous definition.

The *-define_check* and *-define_group* options are mutually exclusive.

`-define_group mega_check_name`

Specifies the name of the mega check to create. See *check_design* for definition of mega-check.

In place of *mega_check_definition*, user should provide a list of atomic-check names. These atomic-check names can be names of any user-defined or pre-defined atomic-checks.

If the specified name is the name of a predefined check (built-in check), the command issues an error message.

If the specified name is the name of an existing user-defined check, the new definition overwrites the previous definition.

The *-define_check* and *-define_group* options are mutually exclusive.

`definition`

Defines the check.

Feedback

When you use the *-define_check* option, this argument defines the atomic check. You must specify a single command with or without its options.

When you use the *-define_group* option, this argument defines the mega check. You must specify a list of atomic-check names. These atomic-check names can be the names of any user-defined or predefined atomic checks.

Description

User can use this command to,

(1) Define a new atomic-check or mega-check, whose name does not match any of the existing pre-defined or user-defined checks. For example, user can define a new check by name say, *my_check* and none of the pre-defined checks or existing user-defined checks have the name *my_check*.

(2) Re-define existing user-defined checks. For example, lets say a user-defined check by name *my_pre_placement_stage* already exists. User can give a new definition to the check *my_pre_placement_stage*, which overrides the previous definition.

To report the checks defined or modified by the *create_check_design_strategy* command, use the *report_check_design_strategy* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

(1) The following example defines a new user-defined check *my_mv_design*,

```
prompt> create_check_design_strategy -define_check my_mv_design  \\
    {check_mv_design -power_connectivity -max_message_count 0}
```

(2) The following example defines a mega-check named *mv_cts* using the existing atomic-checks named mv_design, cts_qor, and legality:

```
prompt> create_check_design_strategy -define_group mv_cts \\
    {mv_design cts_qor legality}
```

Feedback

create_checkpoint_action

Defines an action in the checkpoint system that can then be associated to run at a checkpoint.

Syntax

```
string create_checkpoint_action
action_name
tcl_commands
```

Data Types

```
action_name     string
tcl_commands    list
```

Arguments

action_name

Specifies the name of the action or flow change for the checkpoint system. A mandatory option specifying the name of the flow change. The name of the flow change must be unique, otherwise it will overwrite the previous definition.

tcl_commands

Specifies the block of TCL commands to be associated with the given action or flow change for the checkpoint system.

Description

Defines an action with the given name in the checkpoint system. An action can be any block of one or more Tcl commands. This command defines an action, but it does not execute the action. For an action to run, it must be associated to one or more checkpoints using the associate_checkpoint_action command. An action can be associated to run before, after, or as a replacement for the checkpoint contents.

Actions are used to modify behavior of the default flow. They allow experimental flow changes to be defined independently of the golden flow scripts. They may be defined in the ./checkpoint.config.tcl file in the run directory, which will automatically be sourced by the checkpoint system.

The simplest and most common example is an action which applies an app option setting before a checkpoint. But more complex actions are possible, such as applying multiple tool constraints, or modifying the options on a checkpointed command.

Actions execute at the same script scope as the checkpoint to which they are associated. So, any local variables or other variables made available through the global or upvar commands can be used inside that action. For this reason, ensure that any variables you

Feedback

define inside an action do not conflict with variables defined at the scope in which it will run.

Examples

Defines an action called postroute_ccd that activates the CCD route_opt app option. Then action is then associated to run before the first_route_opt checkpoint. When the first_route_opt checkpoint is executed in the block's flow script, this action will execute beforehand.

```
## checkpoint.config.tcl
create_checkpoint_action postroute_ccd {
           set_app_options -name route_opt.flow.enable_ccd -value true
}

associate_checkpoint_action -enable postroute_ccd -before first_route_opt

## Flow route_opt.tcl script
eval_checkpoint first_route_opt { route_opt }
```

Defines and associates an action to replace the existing create_placement call at the incremental_place checkpoint with an option to force high congestion effort. The get_current_checkpoint -command option is used to access the current checkpointed command contents and modify them with the new option.

```
## checkpoint.config.tcl
create_checkpoint_action high_effort_congestion {
          eval [get_current_checkpoint -command] -congestion
 -congestion_effort high

}

associate_checkpoint_action -enable high_effort_congestion \
          -replace incremental_place

## Flow place_opt.tcl script
eval_checkpoint incremental_place {
          create_placement -incremental -timing_driven
}
```

---

create_checkpoint_report

Defines a report in the checkpoint system that can then be associated to run at a checkpoint.

Syntax

```
string create_checkpoint_report
report_name
tcl_commands
```

Data Types

```
report_name     string
tcl_commands    list
```

Arguments

report_name

Specifies the name of the report for the checkpoint system. A mandatory option specifying the name of the report. The name of the report must be unique, otherwise it will overwrite the previous definition.

tcl_commands

Specifies the block of TCL commands to be associated with the given report for the checkpoint system.

Description

Defines a report with the given name in the checkpoint system. A report can be any block of one or more Tcl commands. This command defines a report, but it does not execute the report. For a report to run, it must be associated to one or more checkpoints using the associate_checkpoint_report command. A report can be associated to run before or after a checkpoint. Unlike actions, reports cannot replace a checkpoint's contents.

Reports are used to generate output from the tool at a checkpoint. They allow report definitions to be defined independently from the golden flow scripts. Each user may apply their preferred reporting setup to write out the required data needed for debugging run

Feedback

results. Typically, reports are defined in the ./checkpoint.config.tcl file in the run directory, which will automatically be sourced by the checkpoint system.

Checkpoint reports are typically used to write out common reports like report_qor, report_timing, check_mv_design, check_routes, other default tool reports, or custom user reports.

Reports execute at their own scope. They do not have access to the variables at the scope of the associated checkpoint, unless they are made available in the create_checkpoint_report body with the Tcl global or upvar command. Any variables you define in the body of create_checkpoint_report will not conflict with variables at the checkpoint scope.

Examples

This example defines a report named timing that generates common timing related reports into the ./checkpoint directory. The get_current_checkpoint -name command is used to get the name of the current checkpoint, which is used to give each written report a unique and meaningful name.

This report is then associated to run after all *-final checkpoint names. When the flow script runs, any eval_checkpoint commands with checkpoint names matching *-final will run this report.

```
## checkpoint.config.tcl
create_checkpoint_report timing {

set name [get_current_checkpoint -name]
redirect -file ./checkpoint/${name}.qor.rpt { report_qor }
redirect -append ./checkpoint/${name}.qor.rpt { report_qor -summary }
redirect -file ./checkpoint/${name}.timing.rpt { report_timing }

}
associate_checkpoint_report -enable timing -after *-final
```

This example defines a report that saves a block to the NDM design database. Since it can be useful to save a before or after an important flow step, the report uses the get_current_checkpoint -position option to uniquely name the saved block, indicating whether it was saved 'before' or 'after' the checkpoint. This report can then be associated to run before or after any checkpoint names where the user wants to save the database.

```
## checkpoint.config.tcl
create_checkpoint_report save_block {

set name [get_current_checkpoint -name]
set position [get_current_checkpoint -position]
save_block -as checkpoint_${position}_${name}

}
```

---

create_clips

Creates a set of clip blocks.

Syntax

int *create_clips*

```
[-clip_library lib]
[-block block]
[-layers layers]
[-no_merge]
name
boundaries
```

Data Types

```
lib         library
block       design
layers      list of layers
name        string
boundaries  list of boundaries
```

Arguments

`-clip_library lib`

Specifies an existing clip library in which to generate the new clip blocks. If you do not provide this option, the clip blocks save into a new autogenerated clip library. This is an optional option.

Feedback

`-block` *block*

Specifies the source block for the clip blocks. If you do not provide this option, the command operates on the current block. This is an optional option.

`-layers` *layers*

Restricts the clipping operation to a subset of layers in the source block. If you do not provide this argument, the clip blocks contain data from all layers in the source block. This is an optional option.

`-no_merge`

Designates that the resulting clip blocks are not tracked for merge. Does not enforce clip region overlap check. This is an optional option.

name

Specifies the name string for the clip blocks. This is a required option.

boundaries

Defines the physical regions of the source block from which to generate the clip blocks. You must provide at least one boundary region. Each boundary region corresponds to the creation of a single clip block. This is a required option.

Description

The *create_clips command* creates copies of the physical data contained within each clip boundary and writes each copy into its own, separate clip block. The command writes the clip blocks into an independent clip library as specified in the command invocation. The clip library points to the tech of its ref libs if it contains its own technology. If a library that is not a clip library is specified in the command invocation then the command issues an error message. The command does not check whether a given clip library correlates with the library of the source block or not. A clip library might contain any number of clip blocks.

Clip blocks contain the following types of physical data:

- Layer shapes (points, rectangles, trapezoids, polygons, lines, paths, text shapes) • Vias (simple, custom, array) • Via matrixes • Via ladders • Fill shapes • Cells • Terminals • Tracks • Site rows/arrays • DRC error markers

  Clip blocks are complete designs, and each clip block necessarily contains portions of the source design's logical netlist that correspond to the copied physical data. However, they are not necessarily closed or valid circuits. For example, a clip region might contain branches of a clock tree that have no source. In this case, the design data is valid. However, many timing and analysis commands might not offer meaningful information. The clipping operation makes no attempt to fix or "complete" parts of the design data to produce a well-formed circuit.

Feedback

Examples

The following command creates a set of 3 clip blocks:

```
prompt> create_clips CLIP {{{0 0} {10 10}} {{20 20} {25 21}} {{100 50}
 {150 100}}}
```

The following command creates a single clip block containing data from only the first metal layer and adds it into an existing clip library:

```
prompt> create_clips -clip_library $myClipLib -layers  /
[get_layers M1] CLIP {{{0 0} {10 0} {10 5} {5 5} {5 10} {0 10}}}
```

See Also

- merge_clips
- report_active_clips

---

create_clock

Creates a clock object.

Syntax

collection *create_clock*

```
-period period_value
[-name clock_name]
[-waveform edge_list]
[-add]
[source_objects]
[-comment comment]
```

Data Types

period_value	float
clock_name	string
edge_list	list
source_objects	list
comment	string

Arguments

`-period` *period_value*

Specifies the clock period in library time units. This is the minimum time over which the clock waveform repeats. The *period_value* must be greater than or equal to zero.

Feedback

`-name` *clock_name*

Specifies the name of the clock being created, enclosed in quotation marks. If you do not use this option, the clock gets the same name as the first clock source specified in the *sources* option. If you did not specify *sources*, you must use the *-name* option, which creates a virtual clock not associated with a port or pin. You can use both the *-name* option and the *sources* option to give the clock a more descriptive name than the first source pin or port. If you specify the *-add* option, you must use the *-name* option and the clocks with the same source must have different names.

`-waveform` *edge_list*

Specifies the rise and fall edge times of the clock waveforms of the clock, in library time units, over an entire clock period. The first time in the *edge_list* is a rising transition, typically the first rising transition after time zero. There must be an even number of edges, and they are assumed to be alternating rise and fall. The edges must be monotonically increasing, except for a special case with two edges, where fall can be less than rise. The numbers should represent one full clock period. If you do not specify this option, a default waveform is assumed, which has a rise edge of 0.0 and a fall edge of *period_value*/2.

`-add`

Specifies whether to add this clock to the existing clock or to overwrite. Use this option to capture the case where multiple clocks must be specified on the same source for simultaneous analysis with different clock waveforms. When you specify this option, you must also use the *-name* option.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the tool must explore all possible combinations of launch and capture clocks. Use the *set_false_path* command to disable unwanted clock combinations.

source_objects

Specifies the objects used as sources of the clock. The sources can be ports, pins or nets in the design. If you do not use this option, you must use the *-name* option, which creates a virtual clock not associated with a port, pin or net. If you specify a clock on a pin that already has a clock, the new clock replaces the old one unless you use the *-add* option. When a net is used as the source, the first driver pin of the net is the actual source used in creating the clock.

`-comment` *comment*

Associate a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

Feedback

Description

Creates a clock object. It is created in the current design and is applied to the specified *sources*.

If successful, the command returns a collection containing the new or modified clock.

If you do not specify a *sources* value, but give a *clock_name* value, a virtual clock is created. You can create a virtual clock to represent an off-chip clock for input or output delay specification. For more information about input and output delay, see the *set_input_delay* and *set_output_delay* man pages.

If one of the *sources* is already the source of a clock, the source is removed from that clock. This clock is eliminated if it has just one source.

The *create_clock* command also defines the waveform for the clock. The clock can have multiple pulses per period.

The *create_clock* command is used together with the *set_clock_latency*, *set_clock_uncertainty*, *set_propagated_clock*, and *set_clock_transition* commands to specify properties of clock networks. By default, a new path group is created for the clock. This new path group brings together the endpoints related to this clock for cost function calculation. To remove the clock from its assigned group, use the *group_path* command to reassign the clock to another group or to the default path group. For more information, see the *group_path* man page.

The new clock has ideal clock latency and transition time; no propagated delay through the clock network is assumed and a transition time of zero is used at the clock source pin. To enable propagated latency for a clock network, use the *set_propagated_clock* command. To set an estimated latency, use the *set_clock_latency* command.

To show information about clocks in the design, use the *report_clock* command. To create a collection of clocks matching a pattern and optionally matching filter criteria, use the *get_clocks* command.

To undo *create_clock*, use the *remove_clock* command.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example creates a clock on a port named *PHI1* with a period of *10.0*, a rise at *5.0*, and a fall at *9.5*.

```
prompt> create_clock PHI1 -period 10 -waveform { 5.0 9.5 }
```

The following example shows a clock named *PHI2* with a falling edge at *5* and a rising edge at *10* with a period of *10*. Because the edges for the *-waveform* option should be

Feedback

ordered as first rise, then fall, and should increase in value, the fall edge can be given as *15*. This places the next falling edge after the first rise edge at *10*.

```
prompt> create_clock PHI2 -period 10 -waveform { 10 15 }
```

The following example creates a virtual clock *PHI2* with a period of *10.0*, a rise at *0.0*, and a fall at *5.0*.

```
prompt> create_clock -name PHI2 -period 10 -waveform {0.0 5.0}
```

The following example creates a clock named *clk2* with multiple sources.

```
prompt> create_clock -name clk2 -period 10 \\
   -waveform {2.0 4.0} {clkgen1/Z clkgen2/Z clkgen3/Z}
```

The following example creates a clock named *CLK* on pin *u13/Z* with a period of *25*, a fall at *0.0*, a rise at *5.0*, a fall at *10.0*, a rise at *15.0*, and so on.

```
prompt> create_clock u13/Z -name CLK -period 25 -waveform { 5 10 15 25}
```

---

create_clock_balance_group

Creates a clock balance group containing clocks or skew groups that need to be balanced together.

Syntax

```
string create_clock_balance_group
-objects object_list
-name group_name
[-offset_latencies offset_value_list]
[-corner corner_name]
```

Feedback

Data Types

object_list	collection
group_name	string
offset_value_list	list
corner_name	string

Arguments

`-objects` *object_list*

Specifies the list of clocks or skew groups to be balanced together. This list cannot contain a combination of clocks and skew groups. Note that objects list should contain at least two objects.

`-name` *group_name*

Specifies the name of the clock balance group.

`-offset_latencies` *offset_value_list*

Specifies the ordered list of offset latency values for the clocks in '-objects' argument. The default value is 0.0 for all objects in the objects list.

`-corner` *corner_name*

Specifies the corner to which the offset latencies are applied.

Description

This command creates a new clock balance group in which all clocks have the similar insertion delay or differences by offset values if '-offset_latencies' is specified. Clocks will be balanced by using the *balance_clock_groups* command.

(a) If no offset latencies are specified, balance_clock_groups takes the longest insertion delay among the objects as the target latency and balances with 0 offset. (b) If offset latency values are set, it balances the clocks and skew groups to achieve the desired insertion delay among them with corresponding offset latencies applied.

Examples

The following example creates a new clock balance group named 'balance_group1'.

```
prompt> create_clock_balance_group -objects {clk1 clk2 clk3} \\
        -name balance_group1 \\
        -offset_latencies { 0.0 0.1 -0.5 }
```

---

create_clock_buffer

Inserts a buffer in the clock tree.

Syntax

string *create_clock_buffer*

```
[-clock clock_name]
[-sinks pins_or_ports]
[-source pin_or_port]
[-replace cell]
[-new_net_name net_name]
[-new_cell_name cell_name]
[-location {x y}]
[-snap true | false]
[-no_legal]
```

Data Types

```
clock_name      string
pins_or_ports   collection
pin_or_port     string
cell            string
net_name        string
cell_name       string
x               float
y               float
```

Arguments

`-clock clocks`

Selects the buffer based on clock-specific buffer selection rules for this clock. By default, no clock-specific buffer selection rules are considered.

`-sinks pins_or_ports`

Specifies the pins or ports to buffer. The newly inserted buffer becomes the driver of these sinks. The specified pins or ports must be driven from the same physical net, and must all be within the same physical hierarchy block. The logical nets might be different.

Exactly one of the options *-sinks*, *-source* or *-replace* must be specified.

Feedback

`-source` *`pins_or_port`*

The pin or port behind which the buffer will be inserted. The newly inserted buffer becomes a sink of this source.

Exactly one of the options *-sinks*, *-source* or *-replace* must be specified.

`-replace` *`cell`*

Replaces an existing buffer with the specified new buffer. The new buffer will be connected in the same way as the old buffer. This option is used to ensure that the buffer honors the CTS buffer selection rules.

Exactly one of the options *-sinks*, *-source* or *-replace* must be specified.

`-new_net_name` *`net_name`*

Specifies a prefix to use for the new net that connects the driver of the sinks to any sinks of that driver which are not driven by the new buffer. Use this option only with the *-sinks* option, since otherwise there will be no such remaining sinks.

`-new_cell_name` *`cell_name`*

Specifies the prefix to use for the new buffer. A number will be added at the end to make the name unique. By default, the prefix is "cts_guide".

`-location {`*`x y`*`}`

Specifies the location to use for the new buffer. The actual location is determined by finding the nearest point not blocked by hard placement blockages or blocks. If there is no top-level free space (as in a fully-abutted design), overlap with a block is allowed.

`-snap true | false`

Specifies whether the buffer should snap to the nearest point that is not covered by a block. By default, snapping is performed, and the tool attempts to find a location at the top-level near to the indicated location to place the buffer. However, if the intention is to push the buffer down into some block, snapping can be disabled with the *-snap false* option. Note that if no top-level area is available (as in a fully-abutted design), then snapping is disabled regardless. Also note that the tool always snaps away from hard placement blockages.

`-no_legal`

Specifies to skip calling legalizer when placing the newly created instance. Default behaviour is to find legal location.

Description

The *create_clock_buffer* command inserts a buffer in front of the specified sets of sinks, using the same rules for buffer selection as the *synthesize_clock_trees* command.

Feedback

Use this command to insert guide buffers in the clock tree before clock tree synthesis to guide the clock tree synthesis.

The command returns the name of the newly inserted buffer.

Examples

Insert a buffer in front of a single sink.

```
prompt> create_clock_buffer -clock CLK -sinks [get_pins cell1/A]
cell1/cts_guide1
```

See Also

- synthesize_clock_trees

---

create_clock_drivers

Creates a set of clock driver cells in the netlist. The clock driver cells are legalized near user-specified locations. The created cells are either buffer cells, or clones of an existing template cell in the netlist. The cells can also be created inside physical hierarchy blocks.

Syntax

```
status create_clock_drivers
-loads net_pin_port_list
[-prefix string]
[-keepouts poly_rect_list]
[-max_displacement distance]
[-locations coordinate_list]
[-boxes integer_pair]
[-boundary poly_rect]
[-lib_cells lib_cell_list]
[-template]
[-input_pin hier_in_pin_list]
[-hierarchy hier_list_per_block]
[-short_outputs]
[-output_net_name string]
[-transfer_wires_from net]
[-configuration config_list]
```

Data Types

```
net_pin_port_list   list or collection of a net or pins and ports
coordinate          {x_coordinate y_coordinate}, in user units
coordinate_list     list of coordinates
net                 a logical net in the block
distance            distance in user units
poly_rect           a polygon definition (see create_poly_rect for
 format)
poly_rect_list      list of poly_rect
```

Feedback

```
lib_cell_list       list of lib_cells
integer_pair        list of two positive integers {columns rows}
hier_in_pin_list    list of hierarchy and input_pin pairs
hier_list_per_block list of physical hierarchy and corresponding logical
 hierarchy pairs
string              a string value
```

Arguments

`-loads` *net_pin_port_list*

The outputs of the inserted cells will drive the loads as specified with the *-loads* option. The *-loads* option takes a single net or a set of load pins and/or ports. If a net is specified, all load pins/ports of that (physical) net form the load pins of the inserted cells. If load pins or ports are specified explicitly, then all the specified pins and ports should initially be connected to the same (physical) net. However, not all sink pins of a net may be specified as load pins. The unspecified sink pins of the net will not be driven by the inserted cells, but will remain connected to the original net. If *-template* option is specified in the Multi-Level Physical Hierarchy flow, a list comprising the output net of the template cell in each physical hierarchy must be specified using this option.

`-prefix` *string*

All newly created cells will get this prefix in front of their name. The default value is *clk_drv*. This same prefix is also applied to the names of new nets or ports that are created for a clock driver.

`-keepouts` *poly_rect_list*

Specifies a list of poly_rects where no driver cells should be placed. If a preferred location is in one of the poly_rects, then no driver will be placed at that location.

`-max_displacement` *distance*

The inserted clock drivers are legalized taking fixed cells, macros, blockages, and other clock cells into account. When after legalization the distance of the cell center to the preferred location is larger than the distance specified with the *-max_displacement* option, no driver will be inserted near that preferred location. By default, no maximum displacement is in effect, and cells will be legalized as close as possible to the preferred location.

`-locations` *coordinate_list*

Specifies a list of preferred locations where cells should be placed. The cells are legalized such that the center of the inserted cells is as close as possible to these coordinates.

Feedback

`-dangling_locations` *`coordinate_list`*

Contains a list of locations which is a subset of list given by the option *-locations*. The output of any cells inserted at the locations specified by *-dangling_locations* would be left dangling.

`-boxes` *`integer_pair`*

The *-boxes* option accepts a list of two positive integers defining the number of columns and rows of a location grid. The bounding box of the boundary is subdivided in equally sized boxes according to the specified number of columns and rows. Then the preferred locations are formed by the centers of these boxes. The boundary can be specified explicitly using the *-boundary* option. If not specified, the boundary of the core area is used.

`-boundary` *`poly_rect`*

Specifies the area in which the inserted cells should be placed. If the preferred location of any of the cells to be inserted is not covered by the area enclosed by the boundary, then the cell will not be inserted. The default boundary is the boundary of the core area.

`-lib_cells` *`lib_cell_list`*

Specifies a list of buffer lib_cells that can be used as clock driver cells. All specified lib_cells should have lib_cell purpose *cts* included. For each preferred location, the corresponding voltage area is queried, and the *first* lib_cell in the list that qualifies for that voltage area will be used for the location. If none of the provided driver types qualifies, then no buffer is inserted at that location. This options is mutually exclusive with the *-template* option if the lib cell of the template is neither a buffer nor an inverter.

`-template`

Specifies that the existing driver cell of the load net (the template cell) should be cloned to create clock driver cells. Using a template cell, it is possible to have inverters or clock gates as clock drivers. All newly created cells will be inserted in same hierarchy level as the original template cell, and are only inserted if the preferred location is in the same voltage area as the original driver. This option is mutually exclusive with the *-lib_cells* option if the lib cell of the template is neither a buffer nor an inverter.

`-input_pin`

Only valid in combination with *-template*. It specifies a list of pairs of hierarchy and the clock input pin of the template cell. This option is required if the template cell has multiple inputs (Example: clock gating cell, multiplexer etc.) and the template is for a level higher than 1 (see *-configuration*). Otherwise it is optional. In the Multi-Level Physical Hierarchy flow, the input pin must be specified for each physical hierarchy where a multi-input template cell exists. A list of pairs

Feedback

of hierarchy name and respective clock pin name needs to be specified. For top level the keyword "TOP" should be used as the hierarchy name.

`-hierarchy` *`hier_list_per_block`*

Specifies a list of pairs of physical hierarchy and corresponding logical hierarchy in which the clock drivers should be inserted. This option is invalid in conjunction with the *-template* option. For top level physical block, as well as top level logical module, the keyword "TOP" should be used as hierarchy name. The logical hierarchy may be specified for few physical blocks and will be auto determined for physical blocks for which the information is not specified.

`-short_outputs`

Specifies that the output pins of the drivers should all be connected to the same physical net. In this way, multi-driven clock meshes or clock straps can be supported.

`-output_net_name` *`string`*

Specifies the name of the shorted output net. This option is only valid when option *-short_outputs* is given.

`-transfer_wires_from` *`net`*

Specifies an existing net with shapes and/or vias. These shapes and vias will be moved from the existing net to the shorted output net of the drivers. This option is only valid when option *-short_outputs* is given.

`-configuration` *`config_list`*

Specifies multiple levels of clock drivers to be inserted. Each entry in the *config_list* corresponds to a clock driver level. An entry is itself a list of options. The following options can be used in a configuration entry:

```
-level integer
[-prefix string]
[-keepouts poly_rect_list]
[-max_displacement distance]
[-locations coordinate_list]
[-dangling_locations coordinate_list]
[-boxes integer_pair]
[-boundary poly_rect]
[-lib_cells lib_cell_list]
[-template]
[-input_pin hier_in_pin_list]
[-hierarchy hier_list_per_block]
[-short_outputs]
[-output_net_name string]
[-transfer_wires_from net]
```

Feedback

The required *-level* option accepts a positive integer indicating the level for the configuration entry. Level 1 is the level near the root, and the level number counts up going towards the leaves of the multi-level clock driver structure. The semantics of the other options is the same as for the corresponding option at the command level. For *-prefix*, *-keepouts*, *-max_displacement*, *-boundary*, and *-lib_cells*, the default value is the value of the command-level corresponding option.

Description

The *create_clock_drivers* command inserts a number of clock buffers into the netlist using the reference library cell specified with the *-lib_cells* option. If you specify more than one buffer library cells, for each inserted buffer, the tool inserts the first usable buffer in the list. The library cell selection process takes power domain and driver/load characteristics into account. The *-loads* option takes a single net or a set of load pins. If a net is specified, then all load pins of that (physical) net form the load pins of the buffers. If load pins are specified explicitly, then all the specified pins should initially be connected to the same (physical) net. However, not all sink pins of a net may be specified as load pins. The unspecified load pins of the net will not be driven by the inserted buffers, but will remain connected to the original net. All specified load pins will be connected to a single inserted clock driver cell. A subsequent tap assignment step is required to distribute the loads over the inserted buffers. The inputs of the inserted repeaters will connect to the original (physical) net of the load pins. If option *-hierarchy* is given, then all buffers will be inserted in the specified hierarchical cell. Otherwise, the tool will choose an appropriate hierarchy level to insert the cells. The number of inserted repeaters is implicitly defined by specifying a number of ideal (preferred) locations. Repeaters will be inserted at legal locations near the specified ideal locations. During legalization, only fixed cells, marked clock cells, and blockages are considered when determining the legal locations. So, inserted repeaters may overlap with existing data path cells or flipflops. In order to end with a legalized design, run the *legalize_placement* command after the *create_clock_drivers* command. Locations can be specified explicitly by using the *-locations* option and/or implicitly through a regular pattern using *-boxes* and *-boundary*. The default boundary is the core area of the block. The *-boxes* option accepts two positive integers defining the number of columns and rows of a location grid. The bounding box of the boundary is subdivided in equally sized boxes according to the specified number of columns and rows. Then the ideal locations are formed by the centers of these boxes. The ideal locations are pre-filtered using the keepout regions and the boundary. If an ideal location is covered by a keepout region or not covered by the boundary area, then that location is not used. The ideal locations define preferred location of the centers of the cells. So, legalization will try to get the center of the buffers as close as possible to the specified locations. If *-max_displacement* is defined and a legalized cell would land more than the specified distance from the ideal location, then the buffer cell will not be inserted. The inserted buffers will have the *physical_status* attribute set to *fixed* and the *user_dont_touch* attribute set to *true*.

Feedback

Using the *-lib_cells* option, only simple repeaters (buffers or inverters) can be specified. If non-repeater cells (e.g. clock gates) are to be placed in a regular pattern, then a template version of the cells should be included in the incoming netlist. By specifying the *-template* option instead of *-lib_cells* (these options are mutually exclusive if the library cell of the template is neither a buffer nor an inverter), the command is instructed to make clones of the unique driver cell of the load pins. The clone insertion follows the same rules as the buffer insertion with respect to keepouts, legalization, and load assignment. A clone will only be inserted when the ideal location is in the same voltage area as the voltage area of the template cell if the template cell is neither a buffer nor an inverter. The clones will be in the same hierarchical level as the template cell. If the template cell is a buffer or inverter and the location is in a different voltage area and hence power domain this implies that the *opt.common.allow_physical_feedthrough* application option must be set to *true*. The *-hierarchy* option is not supported when *-template* is given. When inverters are used as lib_cells, the polarity of the clock should not change. This implies that in the single-level insertion, no inverters can be specified through *-lib_cells* because that would invert the clock. Instead, an inverter should be added to the incoming netlist and *-template* can be used to clone this existing inverter.

The command can also insert multiple levels of clock drivers using the *-configuration* option. For the lowest level, all loads in a voltage area will be connected to a single clock driver in that voltage area. The other clock drivers in the voltage area will have dangling outputs. A subsequent tap assignment step is required to distribute the loads over the clock drivers. For the higher levels, an assignment of the clock drivers at level N to the clock drivers of level N-1 is performed based on proximity. At these non-leaf levels, drivers that have no loads assigned will not be inserted. So at non-leaf levels, there will be no drivers with dangling outputs. This results in a multi-level structure where only one of the leaf drivers (per voltage area) drives the original loads, and the other leaf drivers have dangling outputs.

In all situations, the polarity of the clock should be preserved at all template levels and at the leaves. This implies that an even number of inverter levels should be inserted in between template levels, as well as an overall even number of inverter levels. It is an error if a polarity change would occur, and the command will not insert any cell in that case.

In a multi-level structure, the building of a level should be aware of what input pins of the downstream level are to be driven. For single-input downstream cells (e.g. buffers or inverters) this is clear. For multi-input cells such as clock gates or multiplexers, the input pin of the template cell should be specified explicitly using the *-input_pin* option. This option accepts a string pair consisting of hierarchy of the template cell and the pin name of the lib_cell to be driven by the upsteam level. Since root level 1 does not have a driving level, it is not required to specify the input_pin name for level 1, even if this is a multi-input template level.

This command also supports Multi-Level Physical Hierarchy (MLPH) flow. Using this flow, the cells can be inserted inside physical blocks present at any level of physical hierarchy. To enable this feature, the application option *cts.multisource.enable_mlph_flow* must

Feedback

be set to true. The locations of the cells can be specified using the *-locations* option or the *-boxes* option. The *-locations* option would take the coordinates with respect to top level of design. Based on the top-level location, the cell would be inserted inside the physical block present at that location. The *-hierarchy* option can be used to specify the logical hierarchy in each physical block which should be used for buffer insertion. For top level, the keyword "TOP" must be used for physical hierarchy block and logical hierarchy module. The *-hierarchy* option can be specified in global scope as well as per level. The value for a particular level of buffer insertion will take precedence over global scope.

The MLPH flow supports single level cell insertion as well as multi-level cell insertion using the *-configuration* option. Loads of the original clock net are connected to appropriate cells in the single level cell insertion, while they are connected to appropriate cells in the leaf level in the multi-level cell insertion. The load connectivity is done based on the physical hierarchy of the inserted cells as well as the loads. Loads of the original clock net may reside in different physical hierarchies. In this flow, the loads present in a particular physical hierarchy are connected to any one of the cells inserted in that physical hierarchy. If there are no loads in a physical hierarchy, the output pin of all the cells inserted in that block are left dangling. It is recommended, that the cells should be inserted in all physical blocks in which any loads are present. However, in case there are loads present in a physical block but no cell could be inserted in it, then the loads would be connected to a suitable cell present in a different physical hierarchy.

In the multi-level cell insertion, the load assignment of the non-leaf level cells is done based on the proximity of the loads. This may result in a cell present in a physical block driving loads present in other physical blocks. New logical ports may be created in this process if necessary.

The MLPH flow also supports the *-template* option. If the template cells are to be cloned in different physical hierarchies, then the template cell should pre-exist in all those hierarchies. The output net of the template cells in all physical hierarchies should be provided using the *-loads* option. The template cells present in different physical hierarchies may have different masters. The template cell master in a particular physical block is used for cloning cells in that particular physical block. In case a template cell is present in a physical hierarchy but no location falls on top of that physical hierarchy, then the pre-existing template cell would be deleted. The logical hierarchy of the pre-existing template cells is used for cloned cells in the corresponding physical block. For a multi-input template cell, the input pin which should be used for connection in the clock network should be specified for each hierachy using the -input_pin option.

In the MLPH flow, the physical blocks where cells are to be inserted should be editable and port-punching should also be enabled. The optimization of physical blocks must be enabled using the application option *top_level.optimize_subblocks*. In addition, the MSCTS full MV flow should also be turned ON using the application option *cts.multisource.enable_full_mv_support*. An error message would be generated in case the physical block is read-only.

Feedback

In a typical flow *create_clock_drivers* is used to insert Htree cells/loads. The command *synthesize_multisource_global_clock_trees* is then used to build and route the global clock tree (Htree). This command uses the highest two metal layers allowed for the nets connecting the created cells to route the long distances. These layers can be controlled by using the *set_clock_routing_rules* and *set_routing_rule* commands in conjecture with an explicit nondefault routing rule created with the *create_routing_rule* command. The layers should be within global minimum and maximum layers specified with the *set_ignored_layers* command.

The *create_clock_drivers* command uses the *cts.multisource.enable_pin_accessibility_for_global_clock_trees* application option to control the placement of inserted cells such that they are accessible from the selected Htree routing layers. This ensures good global clock tree (Htree) routing topology and hence the QoR. In cases where command is not used to insert Htree cells/loads, large displacements are observed or cells are dropped it might be useful to set this application option to *false*.

If a clock mesh has been created prior to inserting clock drivers using this command, the tap drives as well as mesh drivers can be snapped close to the clock mesh route shapes. This feature can be enabled using the *cts.multisource.enable_clock_driver_snapping* application option.

To undo the changes made by the *create_clock_drivers* command, use the *remove_clock_drivers* command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example creates a grid of 8 by 8 clock driver cells that drive a multi-driven mesh net named clk1_mesh. The drivers are placed in a regular pattern that covers the full core area (no -boundary option). No drivers will be placed in the bottom-left keepout area. Any existing shapes and vias on net clk1 will be transferred to the newly created mesh net clk1_mesh.

```
prompt> create_clock_drivers -loads [get_net clk1] \\
     -lib_cells [get_lib_cells */CKBUF*] \\
     -boxes {8 8} \\
     -short_outputs \\
     -transfer_wires_from [get_net clk1] \\
     -output_net_name clk1_mesh \\
     -keepouts [list {{0 0} {850 630}} ]
```

The following example creates a grid of 4 by 4 clones of the original driver cell of the load net. On top of that there is an additional clone at the bottom left. If the cells need to move more than 4 um from their preferred location, they will not be inserted.

Feedback

```
prompt> create_clock_drivers -loads [get_net clk] \\
     -template \\
     -boxes {4 4} \\
     -locations [list {0 0}]\\
     -max_displacement 4
```

The following example inserts 4 levels of clock drivers. The first level is a single inverter in the center of the boundary driving 4 inverters at the second level. These drive the CK pin of 16 clones of the original driver of the net. The cloned drivers drive the 64 leaf buffers for which the name starts with HTREE_LEAF. The name of the other inserted driver cells starts with HTREE (the command-level default). For all cells, except the template clones, the maximum allowed displacement is 4 user units. For the template clones, the maximum displacement is 20 user units.

```
prompt> set invs [get_lib_cells */CKINV*]
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_net clk] \\
     -prefix HTREE \\
     -max_displacement 4 \\
     -boundary $boundary \\
     -lib_cells $invs \\
     -configuration [list \\
         [list -level 1 -boxes {1 1}] \\
         [list -level 2 -boxes {2 2}] \\
         [list -level 3 -boxes {4 4} -template -input_pin {{TOP CK}} \\
                        -max_displacement 20] \\
         [list -level 4 -boxes {8 8} -lib_cells $bufs \\
                        -prefix HTREE_LEAF] \\
      ]
```

The following example inserts a single level of clock drivers in 2x2 configuration in the Multi-Level Physical Hierarchy (MLPH) flow.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough
 -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support
 -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value
 true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] -lib_cells $bufs
 -prefix TAP -boxes {2 2}
```

The following example inserts a 4 level buffer tree in the MLPH flow.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough
 -value true
```

Feedback

```
prompt> set_app_options -name cts.multisource.enable_full_mv_support
 -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value
 true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] \\
                             -lib_cells $bufs \\
                             -configuration [list [list -level 1
 -prefix TAP1 -boxes {1 1}] \\
                                                  [list -level 2
 -prefix TAP2 -boxes {2 1}] \\
                                                  [list -level 3
 -prefix TAP3  -boxes {2 2}] \\
                                                  [list -level 4
 -prefix TAP4 -boxes {4 4}] \\
                                                ]
```

The following example inserts a 4 level buffer tree in the MLPH flow in the specified logical hierachies. Assume there are 2 physical hierachies A and C. The buffers are inserted in logical hierachies A1 and C1 inside blocks A and C respectively. Additionally the logical hierarchy I1/I2 inside top block is used for buffer insertion at top level.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough
 -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support
 -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value
 true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets clk] \\
                             -lib_cells $bufs \\
                             -hierarchy {{TOP I1/I2} {A A1} {C C1}} \\
                             -configuration [list [list -level 1
 -prefix TAP1 -boxes {1 1}] \\
                                                  [list -level 2
 -prefix TAP2 -boxes {2 1}] \\
                                                  [list -level 3
 -prefix TAP3  -boxes {2 2}] \\
                                                  [list -level 4
 -prefix TAP4 -boxes {4 4}] \\
                                                ]
```

The following example inserts a 4 level buffer tree in the MLPH flow. The first 3 levels are inserted using the specified lib cells. The 4th level clones the template cell present in different physical hierarchies. Each of the physical hierarchies where cloning is required must already have a template cell instantiated in the netlist.

Feedback

In this example there is a top block with 2 sub-blocks namely “A” and “C”. The output net name of the template cell in top block is “clk1”, while in blocks “A” and “C” it is “A/clk1” and “C/clk1” respectively. All these 3 nets should be specified in the -loads option.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough
 -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support
 -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value
 true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets {clk1 A/clk1 C/clk1}] \\
                             -lib_cells $bufs \\
                             -configuration [list [list -level 1
 -prefix TAP1 -boxes {1 1}] \\
                                                  [list -level 2
 -prefix TAP2 -boxes {2 1}] \\
                                                  [list -level 3
 -prefix TAP3  -boxes {2 2}] \\
                                                  [list -level 4
 -prefix TAP4 -boxes {4 4} -template] \\
                                              ]
```

The following example inserts a 4 level buffer tree in the MLPH flow. The first 3 levels are inserted using the specified lib cells. The 4th level clones the multi-input template cell present in different physical hierarchies.

In this example there is a top block with 2 sub-blocks namely “A” and “C”. The output net name of the template cell in top block is “clk1”, while in blocks “A” and “C” it is “A/clk1” and “C/clk1” respectively. The template cell present in each of the physical hierarchies is a multi-input cell. In top level hierarchy the input pin of template cell to be used for connection is "a0" while in hierarchies "A" and "C", the input pin to be used for connection is "a1". These are specified using the *-input_pin* option. For specifying the top-hierachy the keyword "TOP" is used.

```
prompt> set_editability -blocks  [get_designs -hierarchical] -value  true
prompt> set_app_options -name top_level.optimize_subblocks -value all
prompt> set_app_options -name opt.common.allow_physical_feedthrough
 -value true
prompt> set_app_options -name cts.multisource.enable_full_mv_support
 -value true
prompt> set_app_options -name cts.multisource.enable_mlph_flow -value
 true
prompt> set bufs [get_lib_cells */CKBUF*]
prompt> create_clock_drivers -loads [get_nets {clk1 A/clk1 C/clk1}] \\
                             -lib_cells $bufs -configuration [list \\
                                [list -level 1 -prefix TAP1 -boxes {1
 1}] \\
```

```
                                    [list -level 2 -prefix TAP2 -boxes {2
1}] \\
                                    [list -level 3 -prefix TAP3  -boxes {2
2}] \\
                                    [list -level 4 -prefix TAP4 -boxes {4
4} -template -input_pin {{TOP a0} {A a1} {C a1}}] \\
                                  ]
```

---

create_clock_rp_groups

Creates relative placement groups for leaf level clock tree cells and immediate drivers.

Syntax

int *create_clock_rp_groups*

```
[-min_sinks sinks]
[-max_sinks sinks]
[-distance  distance]
[-timing_driven]
[-max_rp_rows rows   | -auto_shape]
[-cells cell_list]
```

Data Types

```
sinks           integer
distance        float
rows            integer
cell_list       collection
```

Arguments

`-min_sinks sinks`

Specifies the minimum number of sinks that should be driven by a driver cell, to be considered for grouping. If any driver cell is driving less than the given

Feedback

number of sinks then relative placement group will not be created for driver and sinks. The default value is 2.

`-max_sinks` *sinks*

Specifies the maximum number of sinks that should be driven by a driver cell, to be considered for grouping. If any driver cell is driving more than the given number of sinks then relative placement group will not be created for driver and sinks. The default value is 128.

`-distance` *distance*

Specifies the maximum allowed distance between the sinks in one relative placement group. It is manhattan distance in microns. If distance between sinks is more than the given distance then more than one relative placement groups will be created. The default value is 100 microns.

`-timing_driven`

Specifies that the timing critical sinks should not be considered for grouping. By default all the flops having negative slack are not considered.

`-max_rp_rows` *rows*

This option controls the shape of the relative placement group and specifies the maximum number of rows. If total number of cells in relative placement group (sinks and driver) are more than the given rows then multiple columns will be created. The default value for the rows is 32. If number of sinks are 128 or more then shape of relative placement group will be decided automatically.

`-auto_shape`

Specifies that the shape of the relative placement group should be decided automatically. The shape is decided based on the spread of the cells of the relative placement group.

`-cells` *cell_list*

Specifies the list of names or collection of cells to be clustered. If cells are not given then command will consider all cells of the design for grouping.

Description

The *create_clock_rp_groups* command creates relative placement groups for clock tree sinks. Normally one relative placement group is created for one group of sinks being driven by same clock driver and the drive also becomes part of the relative placement group. It can create more than one relative placement group for sinks of same clock driver depending on the options given to the command.

Feedback

Examples

The following example uses the *create_clock_rp_groups* command to create relative placement groups with default values.

```
prompt> create_clock_rp_groups
1
```

The following example uses the *create_clock_rp_groups* command to create relative placement groups, where sinks of one group are not far than 50 microns from each other, and all considered clock drivers drive equal or more than 3 sinks.

```
prompt> create_clock_rp_groups -distance 50 -min_sinks 3
1
```

The following example uses the *create_clock_rp_groups* command to create relative placement groups for clock sinks with maximum 16 rows.

```
prompt> create_clock_rp_groups -max_rp_rows 16
1
```

create_clock_skew_group

Creates a new user-defined skew group.

Syntax

collection *create_clock_skew_group*

```
[-name skew_group_name ]
[-mode mode]
[-clock clock]
-objects object_list
```

Feedback

Data Types

skew_group_name	string
mode	collection
object_list	collection

Arguments

`-name` *skew_group_name*

Specifies the name of the skew group. If not specified the tool generates a unique one on its own.

`-mode` *mode*

Specifies the mode for which the skew group needs to be created. If not specified the current mode is assumed.

`-objects` *object_list*

List of pins and/or ports which need need to be grouped.

`-clock` *clock*

Specifies the clock for which the skew group needs to be created. If not specified the skew group is applied to all the clocks going through the pins.

Description

This command creates a user-defined skew group. Sink pins specified in a skew group will be balanced against each other to meet the specified desired skew and target early delay.

Incremental addition of sink pins in a skew group definition is not supported.

Multicorner-Multimode Support

By default, this command works on the current mode. To specify a different mode, use the *-mode* option.

Examples

The following example creates a skew group for the current mode named grp1 with reg_g2/D1/CK and reg_g2/D2/CK as sink pins:

```
prompt> create_clock_skew_group -name grp1 \\
   -objects {reg_g2/D1/CK reg_g2/D2/CK}
```

See Also

- report_clock_skew_groups
- remove_clock_skew_groups

Feedback

create_clock_straps

Creates straight clock shapes (straps) and vias to implement clock meshes or clock spines. The straps and vias are attached to existing clock nets. A clock mesh is a two-dimensional grid in a horizontal and a vertical layer, where the straps are connected by vias at the intersection points. Clock spine structures can be either one-dimensional or two-dimensional. One dimensional spines, are straps in a single direction. In a two-dimensional spine structure, each *spine* in the spine direction connects to multiple *stripes* in the orthogonal direction. Shapes connected to one spine however, do not connect to shapes of a different spine. This command can generate meshes, one-dimensional spines and two-dimensional spines. It can also create stripes that connect to automatically detected pre-existing spines.

Syntax

```
status create_clock_straps
[-nets net_list]
[-boundary poly_rect]
[-keepouts poly_rect_list]
[-layers layer_list]
[-widths distance_list]
[-grids iterator_list]
[-margins distance_list]
[-create_ends]
[-types type_list]
[-length distance]
[-backoff distance]
[-detect_length distance]
[-spine_direction direction]
[-bias]
[-bias_to_nets net_list]
[-bias_margins distance_list]
[-allow_floating true|false]
[-allow_splitting true|false]
[-clear]
```

Data Types

```
net_list            list or collection of nets
layer_list          list or collection of one or two layers
distance            distance in user units
distance_list       list of one or two distances
type_list           list of one or two types in {user_route stripe detect}
iterator_list       list of one or two grid iterators
poly_rect           a polygon definition (see create_poly_rect for format)
poly_rect_list      list of poly_rect
direction           horizontal or vertical
```

Feedback

Arguments

`-nets` *`net_list`*

For each of the nets, shapes and vias will be created/deleted according to the specification in the other arguments. Typically, a single net will be specified. Multiple nets are only allowed when the *-clear* option is specified or when one of the specified types is *detect*. The specified logical net(s) should exist.

`-boundary` *`poly_rect`*

Specifies the boundary for strap creation. All created shapes are confined to this boundary. The default boundary is the core area of the design.

`-keepouts` *`poly_rect_list`*

Depending on the value of the *-allow_splitting* option, straps will be chopped or skipped such that they do not overlap any of the specified poly_rect's in the keepout list.

`-layers` *`layer_list`*

This command can create net shapes in horizontal, vertical, or both directions. If straps in both directions are required, then specify the horizontal and the vertical layer. If only straps in one direction are required, then specify the layer in that direction.

`-widths` *`distance_list`*

Specifies the width of the straps in horizontal and/or vertical direction.

`-grids` *`iterator_list`*

Specifies the locations (grid-lines) of the straps. For each required direction one iterator should be provided. If both directions are required, the first iterator corresponds to horizontal straps and the second iterator to vertical straps. Each iterator has the form *start* or *{start end step}*. In its first form, only one location (grid-line) is specified. In its second form, a set of locations (grid-lines) is specified : start + i * step, for each integer i with (i >= 0) and (start + i*step <= end).

`-margins` *`distance_list`*

Specifies the maximum distance of a created strap to its specified grid-line. If it is impossible to create the shape within this distance the shape will not be created. The default value is 0, indicating that the straps should be created exactly on the specified grid-lines. If that is not possible, they will be dropped.

`-create_ends`

Specifies that straps should be created on the edges of the bounding box of the boundary as well. These straps are additional to the straps as specified by the

Feedback

grid iterator(s). The boundary can be specified with the -boundary option. Note that only the edges in the specified direction(s) will be considered.

`-types` *`type_list`*

Specifies the type of straps to be created in the corresponding directions. Each type has the value *user_route*, *stripe*, or *detect*. The value *detect* is only valid when also another value is specified. If one of the values is *detect* then we are implicitly in spine creation mode and not in mesh creation mode. Moreover, *detect* indicates that there are already spine shapes in the *detect* direction and that only straps in the other direction should be created. These created straps will connect to the existing spine shapes by means of vias. The created shapes will have their *shape_use* attribute set to their corresponding type-value. Shapes in the *detect* direction are only considered to be part of a spine if their length is at least -detect_length. Also, considered shapes in the *detect* direction are mapped onto the same spine if their distance is smaller than the specified margin in the *detect* direction.

`-length` *`distance`*

Specifies implicitly that we are in spine creation mode. The length specifies the maximum length of the stripes that connect to the detected or created spines.

`-backoff` *`distance`*

Specifies implicitly that we are in spine creation mode. The backoff specifies the minimum distance between stripes of different spines.

`-detect_length` *`distance`*

This option is only valid if one of the specified types is *detect*. Specifies the minimum length of an existing shape in the *detect* layer in order to consider it a spine shape.

`-spine_direction` *`direction`*

Specifies the direction of the spines. This option is not allowed when one of the specified types is *detect*. In that case, the *detect* direction is always the spine direction. This option is required in spine mode if none of the types is *detect*.

`-bias`

Specifies that shielding with existing power or ground nets is preferred.

`-bias_to_nets` *`net_list`*

Specifies that shielding with nets from the net_list is preferred. These nets add to the power and ground nets if the -bias option is used.

`-bias_margins` *`distance_list`*

Specifies how far the shielding shape can be from the specified grid-line of the clock shape. If a shielding shape is found within the specified distance, and

Feedback

the shielding length is at least half of the clock shape, then the clock shape will be created next to the shielding shape. The default bias margin is 0. For the case of spines, which is when -types detect, -length, -backoff or -spine_direction is specified, the bias_margin can be a single value or a tuple. if the value is a single value, it applies to the first layer mentioned -in the -layers list. If there is a second layer, its bias_margin will be default i.e. 0.

`-allow_floating` *`true|false`*

If set to *true*, allow straps in clock meshes or two-dimensional spines that are not connected to a shape in the orthogonal direction. If set to *false*, then straps that do not connect to a shape in the orthogonal direction will be skipped. The default value is *false*.

`-allow_splitting` *`true|false`*

If set to *true*, allow partial or multiple straps at a specified grid line when blockages or keepouts prevent full-length straps. If set to *false*, only allow full-length straps at the grid lines. If a full-length strap cannot be generated due to blockages or keepouts, the strap will be skipped. The default value is *true*.

`-clear`

Remove the straps of the specified nets that were created in previous calls of create_clock_straps.

Description

This command creates a set of horizontal and/or vertical straight net shapes (straps) suitable to build a clock mesh or a clock spine structure. A clock mesh is a two-dimensional grid of metal straps in two orthogonal layers. The straps in one layer are connected to the straps in the orthogonal layer by means of vias or via stacks at the intersection points. A clock spine structure can be one-dimensional or two-dimensional. A one-dimensional spine structure is a set of straps (the spines) in a single layer. A two-dimensional spine structure is a set of *spines* where each spine intersects with a set of *stripes* in the orthogonal direction. Each spine is connected to its stripes at the intersection points by means of vias or via stacks. The straps belonging to one spine do not connect to straps of a different spine. So each strap in the stripe direction is connected to exactly one strap in the spine direction.

The options *-layers*, *-widths*, *-margins*, *-grids*, *-types*, and *-bias_margins* accept a list of one or two values. All these options (if specified) should have the same number of values. If the number of values is one, then one-dimensional spines will be created. If the number of values is two, then a mesh or two-dimensional spines will be created. In the latter case, the first value in each list refers to the horizontal direction, and the second value to the vertical direction. If only one value is given in the lists, then the direction of the specified layer defines the direction of the one-dimensional spines. There is one exception to this rule, however. If one of the two *-types* values is *detect*, then only one grid iterator can be specified. This grid then applies to the non-detect direction.

Feedback

The mesh or stripe structure covers a recti-linear area which can be specified explicitly with the *-boundary* option. The default area is the core area. The area as specified by the *-keepouts* option will not be covered by clock straps. Note that routing blockages and/or existing shapes will also block area and will prevent clock straps from being created at these locations.

The layers of the straps are specified as a list with the *-layers* option. The specified layers should be routing layers. If two layers are specified, these do not have to be adjacent. Connection between orthogonal non-adjacent layers will be made using via stacks. Typically, however, adjacent layers will be used to create clock meshes or two dimensional spines.

The *-widths* option specifies the width of the created straps in the corresponding direction. This is a required option. Typically, clock straps in meshes or spines are wider than the minimum width for the layer. These wider straps have less resistance and result in faster signal propagation in the mesh or spines.

The locations of the clock straps are specified using the *-grids* option. Each item in the list specifies an iterator that defines equidistant positions in the corresponding direction. The format of an iterator is *{start end step}*. E.g. if the corresponding layer is vertical and the iterator is {350 1350 100}, then the iterator defines vertical grid lines at x-coordinates 350, 450, 550, ..., 1350. The iterator values are in user units. These locations are the preferred locations for the clock straps in the corresponding direction.

The command will try to create clock straps at the grid-lines. However, if these grid-lines are off-track, or if part of the grid-lines is blocked, the command can search in the proximity for a better on-track strap location. The search area is defined by the *-margins* option. This option indicates how far the center line of the created strap can be from the specified grid-line.

When the *-create_ends* option is specified, also straps will be created at the edges of the bounding box of the boundary. These straps are additional on top of the straps defined by the *-grids* option. For a rectangular mesh structure, these end straps will create a ring at the edges of the bounding box. For one-dimensional spines, the *-create_ends* option causes two additional spines to be created at the boundary edges in the direction of the spines. For two-dimensional spine structures, the *-create_ends* option only applies to the stripes that are created orthogonal to the spines. So two additional stripes are created at the boundary edges that correspond to the stripe direction.

The *-types* option specifies the *shape_use* attribute of the created straps and vias. Valid shape_use values are *user_route* and *stripe*. If the value is *user_route*, the comb router is not allowed to connect to the shapes. If the value is *stripe*, then the comb router can connect to these shapes. The special type value *detect* can be used to indicate that no shapes should be created in the corresponding direction, but that existing shapes should be identified as spines, and that only stripes should be created. Shapes of both ports and nets can be detected as spine shapes. For existing net shapes to be detected as spines, their *shape_use* attribute should be set to *user_route* or *stripe*. Port (terminal) shapes with

Feedback

shape_use attribute *user_route* or *stripe* will also be detected as spine shapes. When no shapes with shape_use value *user_route* or *stripe* exist on neither the net nor the port then all shapes of the port, irrespective of the shape_use value, will be considered as spines. A value of *detect* implies that a two-dimensional spine structure will be created. Note the terminology here. Stripes are the straps that are orthogonal to the spines. Both spines and stripes can have shape_use *stripe*, although it is typical that the spines have type/shape_use *user_route* and the stripes have type/shape_use *stripe*. When spines are automatically detected, these may belong to different nets. All spines of the specified nets in the *-nets* option will be detected. The stripes of a spine will be attached to the spine's net.

Both the *-length* and the *-backoff* options implies creation of a two-dimensional spine structure. The *-length* option specifies the maximum length of the stripes connected to the spines. The *-backoff* options specifies the minimum distance between stripes of different spines. If the maximum length would violate the backoff value, then the length of the stripe is reduced to honor the backoff value. The default length value is infinite. The default backoff value is twice the minimum spacing rule in the stripe layer.

When the *-types* value is *detect*, the command will identify existing spines. Spine shapes should be in the corresponding layer. The shapes should be owned by either the net or port connected to the net where the straps are created for. If a net or port has shapes with shape_use *user_route* or *stripe* then those shapes will be considered as spines. If no such shapes exist, then any port shape is taken into account, irrespective of the shape_use value. In order for a shape to be considered a spine shape, the width should at least be the corresponding *-widths* value. Multiple spine shapes that are within a distance of the corresponding *-margins* value, are considered to be part of a single pre-existing spine. Only resulting spines with a length longer than the *-detect_length* value are considered as spines for stripe creation.

When a two-dimensional spine structure needs to be created, the spine direction should be specified using the *-spine_direction* option. The spine direction is either *horizontal* or *vertical*.

The location of the created clock straps can be biased such that they are shielded by existing power and ground shapes. Using the *-bias* option, the command will identify power and ground shapes that can be used for shielding. If these shapes are with the corresponding *-bias_margins* value, and the shielded length is at least 50% of the strap length, then the clock strap will be created adjacent to the identified power or ground shape. It is also possible to specify other nets than power and ground nets using the *-bias_to_nets* option. If you use both *-bias* and *-bias_to_nets*, then both power and ground shapes and shapes from the specified bias nets can be used for shielding.

If the value of option *-allow_splitting* is set to *false*, then the command will only create full-length single straps per grid-line. E.g. if a grid-line is partially covered by blockages, keepouts and/or other shapes, then no strap will be created for that gridline. If the value of *-allow_splitting* is set to *true*, then partial and/or multiple straps per grid-line are allowed,

Feedback

and shorter straps may be created in between the blockages. If a stripe strap cannot be connected to a spine shape in the orthogonal direction, then it will not be created unless the *-allow_floating* option is set to *true*. The default value for *-allow_splitting* is *true*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

The following example creates a grid with horizontal straps on M7 and vertical straps on M8. The length of straps is limited by the specified boundary. It includes the top, bottom, left and right straps that form a ring around the mesh. The strap shapes are owned by the net called clk1_mesh. This net should exist. The command inserts horizontal straps near vertical positions 20, 120, 220, ..., 1120. The maximum deviation to these positions is 10. It inserts vertical straps near horizontal positions 60, 210, 360, ..., 960. The width of the straps is 2.4 in both directions. The shape_use attribute of the created shapes will be set to *stripe* (default). A keepout region is created in the botton-left area. Straps that are overlapping with this keepout region will be chopped due to the '-allow_splitting true' option. With '-allow_splitting false', straps that would overlap with the keepout region will be skipped.

```
prompt> create_clock_straps -nets [get_net clk1_mesh] \\
    -boundary {{0 0} {1200 980}} \\
    -layers {M7 M8} \\
    -widths {2.4 2.4} \\
    -grids {{20 1200 100} {60 980 150}} \\
    -margins {10 10} \\
    -create_ends \\
    -keepouts [list {{0 0} {120 240}} ]\\
    -allow_splitting true
```

The following example creates a one-dimensional spine structure. Spines are in horizontal layer M7 and have a width of 3.6. The spines are near locations 50, 170, 290, ..., 770. If a power or ground net can be found within 20 distance of the specified location, then the strap is shifted such that is shielded by the power or ground shape. The shape_use attribute of the created shapes will be set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \\
    -layers M7 \\
    -widths 3.6 \\
    -grids {{50 800 120}} \\
    -margins 10 \\
    -types user_route \\
    -bias -bias_margins 20
```

The following example creates a two-dimensional spine structure. Spines are in vertical layer M8 and have a width of 3.6. The stripes are in horizontal layer M7 and have a width

Feedback

of 2.4. Stripes that cannot connect to their spine will still be created and left floating. The shape_use attribute of the spines will be set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \\
    -layers {M7 M8} \\
    -widths {2.4 3.6} \\
    -grids {{20 1200 100} {60 980 150}} \\
    -margins {10 10} \\
    -types {stripe user_route} \\
    -allow_floating true
```

The following example creates a two-dimensional spine structure based on existing spine shapes in the design (type detect). In effect it will only create the stripes. The created stripes are in horizontal layer M7 and have a width of 2.4. Existing spine shapes should be in layer M8. The minimum width for shapes to be considered as a spine shape is 3.6. When spine shapes are closer than 10 to each other, they will be considered part of a single spine. Only spines with a resulting length of at least 200 will be considered. Since the vertical spines are detected, there is only one grid iterator for the horizontal stripes. The maximum length of a stripe is 110, but if that would violate the backoff value of 5, the stripe length will be reduced. The shape_use attribute of the stripes will be set to *user_route*.

```
prompt> create_clock_straps -nets [get_net clk] \\
    -types {user_route detect} \\
    -layers {M7 M8} \\
    -widths {2.4 3.6} \\
    -grids {{20 1200 100}} \\
    -margins {10 10} \\
    -length 110 \\
    -backoff 5 \\
    -detect_length 200 \\
    -types {user_route detect}
```

---

create_command_group

Creates a new command group.

Feedback

Syntax

string *create_command_group* [-info *info_text*] *group_name*

Arguments

`-info` *info_text*

Help string for the group

group_name

Specifies the name of the new group.

Description

The *create_command_group* command is used to create a new command group, which you can use to separate related user-defined procedures into functional units for the online help facility. When a procedure is created, it is placed in the "Procedures" command group. With the *define_proc_attributes* command, you can move the procedure into the group you created.

The *group_name* can contain any characters, including spaces, as long as it is appropriately quoted. If *group_name* already exists, *create_command_group* quietly ignores the command. The result of *create_command_group* is always an empty string.

Examples

The following example demonstrates the use of the *create_command_group* command:

```
prompt> create_command_group {My Procedures} -info "Useful utilities"

prompt> proc plus {a b} { return [expr $a + $b] }

prompt> define_proc_attributes plus -command_group "My Procedures"

prompt> help
My Procedures:
  plus

 ...
```

See Also

- define_proc_attributes
- help

---

create_comments

Creates one comment

Feedback

Syntax

collection *create_comments*

```
-text text
-line_number line_number
```

Data Types

```
text          string
line_number   integer
```

Arguments

`-text text`

Specifies the data of the comment.

`-line_number line_number`

Specifies the line of the comment.

Description

This command creates a comment in the current design.

Examples

The following example creates one comment in the design with the text "this_is_first_comment" and line number 15.

```
prompt > create_comments -text this_is_first_comment -line_number 15

{"COMMENT_0"}
```

See Also

- remove_comments

---

create_context_for_sub_block

Creates context for block instances.

Syntax

status *create_context_for_sub_block*

```
-block_instance block_instance_name
-nets net_name_list
physical_model_file_name
[-electric_model_file file_name]
```

Feedback

Data Types

```
block_instance_name      string
net_name_list            list
physical_model_file_name string
file_name                string
```

Arguments

-block_istance

Specifies the name of the block instance to generate block context.

-nets

Specifies a list of the nets to generate block context.

physical_model_file_name

Specifies the name of the output physical block context model file.

-electric_model_file

Specifies the name of the output electric block context model file. This option is optional.

Description

This command creates context for the specified block instance. The command models the full-chip environment for the block instance, including physical and electrical models:

o Physical model, which describes the location of the connections between block and full-chip designs. These tap locations are derived by tracing the RedHawk parasitics data. The physical model is generated when the *create_context_for_sub_block* command process is complete, and is written to an output PLOC file.

o Electrical model, which is an effective resistance- and capacitance-based model. The tool uses the native resistance engine to calculate effective resistance which is used to calculate equivalent current during peak dynamic voltage drop analysis. By default, the tool models the full-chip context for the specified blocks. The capacitance data are derived by the RedHawk extraction engine.

o Limitation: this feature only support to create context from Redhawk result

Examples

The following example shows how to create and use the block context during the block-level voltage drop analysis.

```
prompt> open_block top
prompt> ... # IR analysis setup
prompt> analyze_rail ...
```

Feedback

```
prompt> create_context_for_sub_block -block_instance U1 -nets {VDD VSS}
 U1.ploc
prompt> create_context_for_sub_block -block_instance U1 -nets {VDD VSS}
 U1.ploc -electric_model_file U1.context
1

prompt > open_block block
prompt > set_app_options -name rail.pad_files -value U1.ploc
prompt > set_app_options -name rail.block_context_model_file -value
 U1.context
prompt > analyze_rail ...
```

See Also

- rail.pad_files

---

create_corner

Creates a corner in the current design.

Syntax

string *create_corner*

```
[-copy corner_name]
corner_name
```

Data Types

```
corner_name string
```

Arguments

corner_name

Specifies the name of the new corner.

-copy *corner_name*

Specifies the name of the corner to copy from.

Description

This command creates a corner in the current design. Corners are used to contain a set of constraints for the design. Unique corners are used to specify different combinations of operating conditions and parasitic parameters. Corners are used together with modes, which are used for different operating modes and power schemes. Timing analysis done for various mode and corner combinations as configured by the *set_scenario_status* command.

Feedback

Operating condition and parasitics parameters are contained in the current corner. When the design is linked, a single corner named "default" is automatically created and assigned as the current corner. If the *create_corner* command is used, the current_corner is set to the newly-created corner. You can set the current corner to a different corner with the *current_corner* command.

To create a collection of corners matching a pattern and optionally matching filter criteria, use the *get_corners* command. To get a collection of all corners in the design, use the *all_corners* command.

To undo the *create_corner* command, or remove a corner, use the *remove_corners* command.

Examples

The following example creates a corner named "LowVoltage5" and assigns it as the current corner.

```
prompt> create_corner LowVoltage5
```

See Also

- all_corners
- current_corner
- get_corners

---

create_curved_poly_rect

Creates a collection of curved polygon objects.

Syntax

collection *create_curved_poly_rect*

```
-point_list  points
[-layer layer]
```

Data Types

```
points          list
layer           string
```

Feedback

Arguments

`-point_list` *points*

Specifies a list of curved points that specify the boundaries of the curved_poly_rect objects.

Specify the curved polygon in the following format {{*x1 y1*} {*x2 y2 xx2 yy2 convex*} {*x3 y3*}{*x4 y4 xx4 yy4 convex*}...} {{*x5 y5*} {*x6 y6 xx6 yy6 convex*} {*x7 y7*} {*x8 y8 xx8 yy8 convex*}...}

This is a required option.

`-layer` *layer*

Specifies a layer to associate with each curved_poly_rect object in the result. By default, the curved_poly_rects object is not associated with any layer. This option associates each curved_poly_rect object in the result collection to the layer specified in the *layer* argument.

Description

This command creates a new curved polygon object for the curved polygon in the specified list of curved points, and returns a collection that contains the new object.

You must specify the curved boundary of the object, as list of curved points. You can optionally specify layer to associate with each object in the result collection.

Examples

The following example creates a curved_poly_rect object.

```
prompt> create_curved_poly_rect \\
   -point_list { {0 2} {0 8 2 8 true} {2 10} {8 10 8 8 true} \\
    {10 8} {10 2 8 2 true} {8 0} {2 0 2 2 true} } -layer {M1}
```

---

create_custom_shields

Creates custom shielding for the specified nets with Custom Router, if the nets have shield constraints in effect.

Feedback

Syntax

status *create_custom_shields*

```
[-nets nets]
[-keep_session true | false]
```

Data Types

```
nets     collection
```

Arguments

`-nets nets`

Specifies the collection of nets to be shielded. If not specified, the entire design will be shielded. Nets without shielding constraints will be skipped.

`-keep_session true | false`

Specifies whether or not the custom router view of the data will be retained after the command completes. Use true only if you expect to perform additional custom route commands immediately after the current command. The default is false.

Description

The *create_custom_shields* command creates custom shielding shapes for a set of specified nets.

---

create_cut_metals

This command creates cut metals at metal cut ends.

Syntax

status *create_cut_metals*

Description

This command creates cut metals at metal cut ends before gdsout. Tool creates cut metals based on the dimensions and the rules defined in the technology file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

```
prompt> create_cut_metals
```

Feedback

See Also

- remove_cut_metals

---

create_default_topology_plans

Create a default topology plan for a bundle.

Syntax

collection *create_default_topology_plans*

```
[-net_estimation_rule rule_name]
[-allow_feedthrough none | select_on | select_off | all]
[-allow_feedthrough_type pure | mixed | any]
[-allow_feedthrough_select object_list]
[-allow_flyover none | select_on | select_off | all]
[-allow_flyover_select object_list]
[-launch_budget float]
[-capture_budget float]
[-comment comment]
[-group group]
[-shield_placement outside | interleave | double_interleave |
 half_interleave]
[-shield_nets object_list]
[-color color]
[bundle_list]
```

Data Types

```
bundle_list  collection
object_list  collection
rule_name    string
comment      string
group        collection
color        string
```

Arguments

bundle_list

Specifies the list of bundles to create default topology plans. If not specified then it means all the bundles within the current design.

-net_estimation_rule *rule_name*

Specifies the name of the net_estimation_rule of the topology_plan.

-allow_feedthrough none | select_on | select_off | all

Specifies the allow_feedthrough setting of the topology_plan.

"none" indicates that no feedthrough is allowed for the plan.

Feedback

"select_on" indicates that feedthrough is only allowed through the objects specified in the *-allow_feedthrough_select* option.

"select_off" indicates that feedthrough is allowed through all objects except those specified in the *-allow_feedthrough_select* option.

"all" indicates that feedthrough is allowed through all objects.

`-allow_feedthrough_type pure | mixed | any`

Specifies the allow_feedthrough_type setting of the topology_plan.

`-allow_feedthrough_select` *`object_list`*

Specifies the collection of objects for which the *-allow_feedthrough_select* option is applied.

`-allow_flyover none | select_on | select_off | all`

Specifies the allow_flyover setting of the topology_plan.

"none" indicates that no flyover is allowed for the plan.

"select_on" indicates that flyover is only allowed over the objects specified in the *-allow_flyover_select* option.

"select_off" indicates that flyover is allowed over all objects except those specified in the *-allow_flyover_select* option.

"all" indicates that flyover is allowed over all objects.

`-allow_flyover_select` *`object_list`*

Specifies the collection of objects for which the *-allow_flyover_select* option is applied.

`-launch_budget` *`float`*

Specifies the launch budget of the topology_plan.

`-capture_budget` *`float`*

Specifies the capture budget of the topology_plan.

`-comment` *`comment`*

Specifies the comment of the topology_plan. This is a general-purpose string that can be used for documentation.

`-color` *`color`*

Specifies the color of the topology_plan, where color is a 24-bit RGB or 32-bit RGBA hexadecimal string prefaced by '#', for example: "#72c4f1" or "#ce8322ef".

Feedback

`-group` *group*

Specifies that this topology_plan should be added to the specified topology_group. Note that a topology_plan must always belong to a topology_group.

This is an optional argument. If unspecified, the topology_plan will be added to the current topology_group. If there is no current topology_group, then the topology_plan will be added to the default topology_group.

`-shield_placement outside | interleave | double_interleave | half_interleave`

Specifies the shield placement of the topology_plan.

`-shield_nets` *object_list*

Specifies the shield nets of the topology_plan. Allowed object types are nets, supernets, and bundles.

Description

The *create_default_topology_plans* command creates a default topology plan for each of the bundle specified by *bundle_list*, or all bundles if not specified, if the corresponding bundle does not have an associated topology plan.

Note that only bundle of supernets are supported. And the supernets must anchor on one of the followings:

- Hierarchical block pins.
- Hardmacro pins.
- Top ports.

For each bundle that the command is to create a topology plan, there will be one topology node created for the driver block, and one topology node created for each of the load block, and one topology edge per each pair of the node of the driver block and the node of the load block.

Every topology_plan belongs to a topology_group, which can be specified using the *-group* argument. The new topology_plan is created in the group's block when the *-group* argument is specified, otherwise it is created in the current block.

If the command line options *-net_estimation_rule*, *-allow_feedthrough*, *-allow_feedthrough_type*, *-allow_feedthrough_select*, *-allow_flyover*, *-allow_flyover_select*, *-lauch_budget*, *-capture_budget*, *-color*, *-shield_nets*, *-shield_placement*, or *-comment* are provided, they will be applied to the created topology plans as well.

Upon success, the command returns the list of topology plans created.

Feedback

Examples

The following example creates default topology plans for all bundles of the current design.

```
prompt> create_default_topology_plans
```

---

create_dense_tap_cells

Inserts tap cells with a dense pattern within the specified region. For regions with intensified substrate noise, the command also inserts tap walls along the region boundary.

Syntax

status *create_dense_tap_cells*

```
-lib_cell cell_name
-distance tap_distance
[-bbox coordinates]
[-offset distance]
[-pattern every_row | every_other_row | stagger]
[-skip_fixed_cells]
[-prefix cell_prefix]
[-separator cell_separator]
[-at_distance_only]
[-isn_layer layer_list]
[-isn_layer_distance { {{layer1 distance1 layer_offset1} {layer2
 distance2 layer_offset2} ...}]
[-boundary_lib_cell cell_name]
[-horizontal_boundary_spacing spacing]
[-left_boundary_flipped]
[-right_boundary_flipped]
```

Data Types

cell_name	string
tap_distance	float
coordinates	rectangle
distance	float
cell_prefix	string
cell_separator	string
layer_list	list
spacing	float

Arguments

`-lib_cell` *cell_name*

Specifies the library cell that is used as the tap cell. You must specify a single library cell. This is a required option.

Feedback

`-distance` *`tap_distance`*

Specifies the distance in microns between two tap cells in a row. This distance is referred to as the tap distance. This is a required option.

The tap distance specified for this command is typically shorter than the tap distance used by the *create_tap_cells* command, which creates a denser tap cell pattern.

`-bbox` *`coordinates`*

Specifies the rectangular region in which to insert the tap cells. A rectangle is specified as a list of four coordinates, {*{llx lly} {urx ury}*}, which represent the lower-left and upper-right corners of the rectangle in microns.

If you do not use this option or the *-isn_layer* and *-isn_layer_distance* options, the command will error out. This option cannot be specified with the *-isn_layer* and *-isn_layer_distance* options.

`-offset` *`distance`*

Specifies the distance in microns that the tap pattern should be shifted to the right. This option does not set the absolute location of the tap cells, only shifts the existing pattern.

If the offset distance is a multiple of the tap distance, the effective offset is 0. For example, if the tap distance is 10 microns and the offset is 32 microns, the effective offset is 2 (32 - 3x10).

The default is 0.

`-pattern every_row | every_other_row | stagger`

Specifies the tap cell insertion pattern. The supported patterns are

- *every_row* (the default)

  The command adds tap cells to every row using the specified tap distance. The tap distance specified for this pattern should be approximately twice the design rule distance limit.

- *every_other_row*

  The command adds tap cells to every other row for odd rows only. This reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately twice the design rule distance limit.

- *stagger*

  The command adds tap cells to every row. The tap cells on even rows are offset with half the tap distance relative to the odd rows, producing a

Feedback

checkerboard-like pattern. This pattern also reduces the number of required tap cells by approximately half as compared to the normal pattern. The tap distance specified for this pattern should be approximately four times the design rule distance limit.

`-skip_fixed_cells`

Prevents the command from inserting tap cells in locations that are occupied by fixed cells.

When you use this option, the tool treats a fixed cell like a blockage, which breaks the row and might cause a tap cell to be inserted on each side of the fixed cell. To prevent the insertion of tap cells that overlap fixed cells without breaking the row, use the *-preserve_distance_continuity* option with the *-skip_fixed_cells* option.

By default, the command inserts a tap cell in each calculated tap location, even if it is occupied by a fixed cell.

`-prefix` *`cell_prefix`*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

`tapfiller!`*`cell_prefix`*`!`*`lib_cell`*`!`*`number`*

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

`tapfiller!`*`lib_cell`*`!`*`number`*

`-separator` *`cell_separator`*

Specifies the separator character that is used when composing the instance name of the tap cell.

The default is "!".

`-at_distance_only`

Creates tap cells only at the specified distance, distance/2, or distance/4 (stagger mode). Note that using this option can cause DRC violations.

`-isn_layer` *`layer_list`*

Specifies the special non-manufacturing layers defined in the technology file that is used to identify regions where the silicon substrate is subject to intensified substrate noise (ISN).

When a design, hard macro, or soft macro has a substrate noise source, an ISN layer rectangle is specified within a certain radius of the noise source.

Feedback

If you do not use this option or the *-bbox* and *-isn_layer_distance* options, the command will error out. This option cannot be specified with the *-bbox* and *-isn_layer_distance* options.

`-isn_layer_distance { {{layer1 distance1 layer_offset1} {layer2 distance2 layer_offset2} ...}`

Specifies multiple ISN layers, their corresponding tap distances and layers' corresponding shifting value to right for intensified substrate noise regions. The dense tap cells will be inserted in the order of the least dense to the most dense regions. If the layers overlap, the most dense tap distance will prevail. The layer names must not duplicate. When this options is used, the -isn_layer and the -distance options are not allowed. For the input value, "layer" and "distance" value are required, "offset" value is optional and the default value is 0.

If you do not use this option or the *-bbox* and *-isn_layer* options, the command will error out. This option cannot be specified with the *-bbox* and *-isn_layer* options.

`-boundary_lib_cell` *`cell_name`*

Specifies the library cell used to create the tap walls. You can specify only a single library cell.

When you use this option, the command performs the following tasks:

1. Inserts vertical tap walls along the left and right edges of the placeable area boundary.
2. Inserts horizontal tap walls along the top and bottom edges of the placeable area boundary.
3. Marks the inserted tap cells as FIXED.

`-horizontal_boundary_spacing` *`spacing`*

Specifies the spacing between two tap cells in microns for horizontal tap walls. If the spacing value is not multiple of the site width, it will be rounded to the smaller value that is a multiple of the site width. If the value is less than the width of the tap cell or not specified, there will be no spacing between two tap cells.

The default is 0.

`-left_boundary_flipped`

Flips the cells of tap walls on the left boundary.

`-right_boundary_flipped`

Flips the cells of tap walls on the right boundary.

Feedback

Description

The *create_dense_tap_cells* command inserts a dense pattern of tap cells in the specified regions. Before using this command, you must use the *create_tap_cells* command to perform standard tap cell insertion.

The tap walls and dense tap cells are necessary to ensure proper operation of the digital circuit. The tap walls and cell placement observe the prohibited vertical abutment rules.

Within the specified region, the command performs the following tasks:

1. Deletes the existing tap cells.
2. Reinserts the tap cells using the pitch specified with the *-distance* or *-isn_layer_distance* option.
3. Marks the inserted tap cells as FIXED.

You can also perform dense tap cell insertion in intensified substrate noise (ISN) regions by using the *-isn_layer* or *-isn_layer_distance* option. For details about the insertion process for ISN regions, see the description for the *-isn_layer*, *-isn_layer_distance* and *-boundary_lib_cell* options.

If you specify the *-boundary_lib_cell* option, the command also inserts tap walls along each region boundary of specified region. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cell in the library contain no substrate or well taps.

Examples

The following example inserts dense tap cells in the ISN region.

```
prompt> create_dense_tap_cells -lib_cell myLib/Cell1 \\
   -isn_layer LUP_075 -distance 30
```

---

create_density_rule

Creates a density rule in a block or technology file.

Feedback

Syntax

collection *create_density_rule*

```
[-library library]
[-tech tech]
[-max_density intValue]
[-min_density intValue]
[-window_size floatValue]
-layer layer_name
[-max_gradient_density intValue]
```

Data Types

```
library              collection
tech                 collection
floatValue           float
layer_name                string
intValue             integer
```

Arguments

`-library library`

Specifies the library in which to create the density rule. The density rule is added to the technology data contained by or referenced by the specified library.

If you do not specify this option or the *-tech* option, the density rule is created in the technology data of the current library.

`-tech tech`

Specifies the technology data in which to create the density rule.

If you do not specify this option or the *-library* option, the density rule is created in the technology data of the current library.

`-max_density intValue`

Defines the maximum percentage of metal allowed in the window.

`-min_density {intValue}`

Defines the minimum percentage of metal allowed in the window.

`-window_size {float value}`

Defines the size of the window for the density check.

By default, the window step size is half of the defined window size.

`-layer layer_name`

Defines the metal layer for which the rule is specified.

Feedback

This is a required option.

`-max_gradient_density {floatValue}`

Specifies the maximum allowable change in fill density between adjacent windows.

Description

The *create_density_rule* command creates a new density rule in the specified technology data and returns a collection of the created object.

The *signoff_create_metal_fill* command uses the density rules during metal fill insertion.

Typically, density rules are defined in the *DensityRule* sections in a technology file. The technology file should contain a *DensityRule* section for each metal layer.

Examples

The following example creates a density rule in the technology data of the current library.

```
prompt> create_density_rule -max_density 61 -min_density 11 \\
   -layer M1 -window_size 101.00 -max_gradient_density 21
```

See Also

- get_density_rules
- remove_density_rules
- signoff_create_metal_fill

---

create_design_rule

Creates a design rule (design_rule) in the specified technology object.

Syntax

collection *create_design_rule*

```
[-tech tech_object]
[-library library]
-layer1 layer
-layer2 layer
-min_spacing distance
```

Data Types

tech_object	collection
library	collection
layer	collection
distance	float

Feedback

Arguments

`-tech` *tech_object*

Specifies the technology object in which design rule need to be created.

The *-tech* and *-library* options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

`-library` *library*

Specifies the library in which to create the design rule. The command creates the rule in the technology object associated with the specified library. In an implementation tool, the library is a design library. In the library manager, the library is a cell library. You can specify the library using the library's name or a collection that contains the library.

The *-tech* and *-library* options are mutually exclusive; you can specify only one. If you do not specify either option, the rule is created in the technology object of the current library.

`-layer1` *layer*

Specified the first layer of two layers between which design rule need to be created. This option takes collection as input. User must provide valid layer object or layer number as input.

`-layer2` *layer*

Specified the second layer of two layers between which design rule need to be created. This option takes collection as input. User must provide valid layer object or layer number as input.

`-min_spacing` *distance*

Specified the minimum spacing between the layers on which design rule exists. This option takes distance as input i.e. floating point number that represents the spacing in microns.

Description

This command creates a new design rule in the specified technology object. The tool treats the rule same as a rule defined in the DesignRule section of the technology file. For more information about defining design rules, see the "DesignRule Section" in the *Synopsys Technology File and Routing Rules Reference Manual*.

If the command is successful, it returns a collection that contains the created rule; otherwise, it returns an empty string. If there is a command syntax error, it returns a TCL_ERROR.

Feedback

Examples

The following example creates a design rule in the technology object of the current library.

```
prompt> create_design_rule -layer1 [get_layers M3] \\
   -layer2 [get_layers M4] - min_spacing 1.1
```

See Also

---

create_dff_trace_filters

Adds filter patterns to the list of filters used by the *compute_dff_connections* command

Syntax

```
create_dff_trace_filters
-type pin | net
-patterns list_of_patterns
-filename filename
[-blocks list_of_blocks]
```

Data Types

```
list_of_patterns  list
filename          string
list_of_blocks    list
```

Arguments

`-type pin | net`

Specifies the type of filter to add, either *pin* or *net*. This indicates which type of objects the patterns will be matched against: either pins (and ports) or nets.

`-patterns list_of_patterns`

Specifies a list of patterns to add to the indicated filter type list. A pattern can be a local name (path relative to the parent block cell), or a global name for the top block. Patterns support the simple wildcard characters "*" and "?". Regular expressions are not supported. Patterns are NOT verified at insertion time and it is possible to insert patterns that do not match anything in the current design.

Feedback

`-filename` *`filename`*

Specifies that the set of filter patterns is read from a file. The file is generated by a previously saved trace filter file written by the *write_dff_trace_filters* command. This option is mutually exclusive with all other options.

`-blocks` *`list_of_blocks`*

Specifies a list of block names to use as the base name for this pattern when searching for pin/port/net objects. If *-blocks* is not specified, the default implies a special "all blocks" list, and the associated patterns will be tried against all blocks in the current design. Block names do not support wildcard characters. Block names are not verified at insertion time. It is possible to insert block names that do not match any blocks in the current design.

Description

This command creates trace filter patterns used by the Data Flow Flylines (DFF) tracer command *compute_dff_connections*. Any patterns inserted into this list are applied by the DFF tracer as "stop pins/ports" or "stop nets". Any pin/port or net matched by a pattern will stop the DFF tracer from proceeding any further down this path segment.

A GUI interface to manage filter patterns is available as part of the DFF Gui component's Reload option.

BLOCK NAMES, PATTERNS and ABSTRACTS/MIBs

Block names should represent the names of physical blocks used in the main design. For example, the output of *get_attribute [get_designs] name* provides valid block names. Patterns should then be relative to the block, rather than to the global instance name (unless they belong to the top-level design). For example, if an abstract design B1 is linked in the current design as TOP/MORE/INST_B1 and there exists a macro pin TOP/MORE/INST_B1/M1/p1, then to add this pin as a filter pin, the arguments would be: *-block B1 -patterns M1/p1*.

This separation of reference block name and instance name is necessary when tracing through abstracts. When abstracts are loaded in design view for tracing, they are loaded as the main design of that session, and so the instance prefix is discarded. That is, when abstract B1 is traced, the correct path to the macro pin is just M1/p1 with no other path prefix. Separating the patterns in this manner makes this transition seamless.

If abstract design B1 is also a multiply instantiated block (MIB), the situation is even more complicated. There could exist two instances of block B1 at TOP/MORE/INST_B1a and TOP/MORE/INST_B1b. If a filter pin pattern was now specified as TOP/MORE/INST_B1a/M1/p, you might expect that only the macro pin in INST_B1a would be filtered, but not the one in INST_B1b. However, block B1 is only traced one time, and it cannot be traced both with and without the filter pin. That is, filtering a pin in only SOME instances of a MIB is not supported to avoid confusion. It would be possible if the block was in design view, but then fail if the block was later switched to an abstract view. To avoid this problem, this type of

Feedback

unpredictable pattern is discouraged. When using the *-filename* option, a warning is issued if a pattern is read-in that matches only SOME instances of a MIB by using a global path.

The special "all blocks" list is available for global patterns like matching all scan pins in the design, if they have a specific character pattern that can match them like "SCAN". One pattern for each level of the netlist is still required. Since this could easily match unwanted pins or nets, its use should be reserved for special situations.

PATTERN MATCHING

When the DFF tracer runs, it will process each pattern in turn, and for each block that has an instance in the current session, it will apply the pattern to the instance path of that block. This means that the same pattern file can be used with a design with physical hierarchy, whether the blocks are in design view or abstract view. Switching back and forth should not affect the interpretation of filter patterns.

GENERAL USAGE

This command prepares a list of filter patterns to be used by the *compute_dff_connections* command when tracing through the netlist. The block names and patterns are not verified to exist at insertion time. Rather, at runtime, only those patterns matching a netlist object will be applied. This allows the use of only global filter patterns file for an entire project, whether working on the whole design, or just one block.

Examples

The following example adds a pattern "M1/*" to the trace filter list to filter out all pins of macro M1 in block p0.

```
prompt> create_dff_trace_filters -type pin -blocks p0 -patterns "M1/*"
```

See Also

- compute_dff_connections
- remove_dff_trace_filters
- write_dff_trace_filters

---

create_dft_netlist

Creates a DFT netlist from the current design.

Syntax

status *create_dft_netlist*

```
-type extest
```

Feedback

Arguments

`-type extest`

Specifies the type of DFT netlist to create. There is only one valid type supported:

- *-type extest*

  This DFT netlist type removes all logic in the design except that needed to operate in the outward-facing EXTEST mode. Only the following logic types are kept: wrapper chains and wrapper control logic, interface logic between wrapper chains and I/O ports, test mode decode logic, and 1500 controller and any other logic required for EXTEST operation.

  This DFT netlist type is supported only for wrapped cores.

Description

The *create_dft_netlist* command creates a DFT netlist from the current design. Currently only one type, *extest*, is supported

This command modifies the current design in memory. After running it, write out the DFT netlist file using the *write_verilog* command. Because the *create_dft_netlist* command removes logic from the design in memory, these should be the last steps in your core creation script.

This command cannot be used in an ILM generation flow.

Examples

The following example creates and writes out an EXTEST-only netlist: after writing the full-netlist design files:

```
# insert DFT IP and compile
insert_dft
compile

# write block-level design
save_block -as post_compile

# write an EXTEST-only netlist
create_dft_netlist -type extest
write_verilog block_1_EXTEST.vg
```

See Also

- set_wrapper_configuration

Feedback

create_die

Instantiates a die or a stack of die instances in the current design

Syntax

collection *create_die*

```
-location coordinate
-z_offset value
-orientation orientation
[-stack number]
die_name
die_block_reference
```

Data Types

coordinate	list
value	int
orientation	string
number	int
die_name	string
die_block_reference	string

Arguments

`-location`

Specifies the location of the die in the current design. The values of x and y are in the unit of micron. The value of z is a non-negative integer with lower z value at the bottom. For a die stack, specifies the bottom-most z location. All dies in the stack have the same x and y location with one level z increment.

`-z_offset` *value*

Specifies the z location of the die.

`-orientation` *orientation*

Specifies the orientation of bond pads in the array. Value can be one of: *R0, R90, R180, R270, MX, MXR90, MY, MYR90, N, W, S, E, FN, FW, FS, FE*

`-stack` *number*

Specifies the number of dies in the die stack. If unspecified, only one die is created.

die_name

Specifies the die name.

die_block_reference

Specifies the referenced die block.

Feedback

Description

The *create_die* command instantiates a die or a stack of die instances in the current design which is a 3DIC environment. A stack of dies has identical process technology, width, height, x and y locations. The *die_block_reference* might be a die block that has been previously created i with the *create_die_block* command.

Examples

The following example creates a new block named top in the current library created by *create_lib*.

```
prompt> create_die si_interposer_inst interposer:si_interposer -location
 {0 0} -z_offset 0 -orientation N
{si_interposer_inst}
```

See Also

- create_die_block
- create_bump_block

---

create_die_block

Creates a die block in the target library.

Syntax

collection *create_die_block*

```
[-force]
-dimensions dimensions_list
[-origin coordinate]
[-library lib_name]
[-design_type design_type]
[-keep_block]
die_block_name
```

Data Types

dimensions_list	list
coordinate	list
lib_name	string
design_type	string
die_block_name	string

Feedback

Arguments

`-force`

Overwrites the block if one with the same name already exists in the current library.

`-dimensions` *`dimensions_list`*

Specifies the width and height of the die block in micron.

`-origin` *`coordinate`*

Specifies the coordinate of origin.

`-library` *`lib_name`*

Specifies the target library that contains the process technology of the die block to be created. Creating the die in the current library is not recommended as the current design is a 3DIC environment that might contain multiple process technology.

`-design_type` *`design_type`*

Specifies the type of the die. The value can be one of: *die*, *interposer*. The default is *die* type. An interposer is a large die that encompass all other dies in a 2.5D package. A bridge is a small die that offers lateral interconnect within a small local region between two dies.A substrate is a multiple metal layer non-silicon substrate for fanout RDL routing. The design types "bridge" and "substrate" are deprecated.

`die_block_name`

Specifies the die block name.

`-keep_block`

Retain the current block rather than opening the new created block.

Description

The *create_die_block* command creates a die block in the target library. The die block created is empty and should be populated later.

Examples

The following example creates a new block named si_interposer in the library top.exp.

```
prompt> create_lib top.exp
{top.exp}
prompt> create_die_block si_interposer -force -dimensions {15000 10000}
 -library top.exp -design_type interposer -origin {0 0}
```

Feedback

```
Information: Creating block 'si_interposer.design' in library 'top.exp'.
 (DES-013)
{top.exp:si_interposer.design}
```

- create_lib

---

create_differential_group

Creates an analog constraint group with differential_pair or differential_group intent in the current design.

Syntax

collection *create_differential_group*

```
[constraint_group_name]
-for objects
[-twist_style default | diagonal | orthogonal | none]
[-twist_interval distance]
[-twist_offset distance]
[-gap distance]
[-shield_placement default | double_interleave | half_interleave |
 interleave | outside]
[-valid_layers layers]
[-layer_spacings layer_spacing_pairs]
[-layer_widths layer_width_pairs]
[-force]
```

Data Types

constraint_group_name	string
objects	collection
distance	float
layers	collection
layer_spacing_pairs	list
layer_width_pairs	list

Arguments

constraint_group_name

Specifies the name of the constraint group. By default, the command generates a unique constraint group named "differential_pair_n", where n is a unique, monotonically increasing integer value.

Feedback

`-for` *objects*

Specifies the net objects in the analog constraint group. The *objects* argument can be a collection of objects or a string that contains the name of the objects.

`-twist_style default | diagonal | orthogonal | none`

Specifies how the nets of the constraint group will be twisted. The allowed values are default, diagonal, none and orthogonal. Default is none.

`-twist_interval` *distance*

Specifies the twist interval between the nets in the constraint group. This is applicable only when twist style is not none. The default is zero.

`-twist_offset` *distance*

Specifies the twist offset for the nets in the constraint group. This is applicable only when *-twist_style* is not none. The default is zero.

`-gap` *distance*

Specifies the spacing between the outermost bit nets and other shapes in the block. The default is zero.

`-shield_placement default | double_interleave | half_interleave | interleave | outside`

Specifies how the main bus trunk will be shielded if one or more nets of the constraint group are shielded. Allowed values are default, double_interleave, half_interleave, interleave and outside. The default is "default".

`-valid_layers` *layers*

Specifies the list of layer names to be used for the main trunk. If specified, layers type is set to range, otherwise it is set to default. When specified, the min and max layers are derived from the list.

`-layer_spacings` *layer_spacing_pairs*

Specifies the layer and spacing pairs used in trunk routing. This is a list of alternating layer and spacing, for example, {M1 3.0 M2 4.0}.

`-layer_widths` *layer_width_pairs*

Specifies the layer and width pairs used in trunk routing. This is a list of alternating layer and width, for example, {M1 3.0 M2 4.0}.

`-force`

Deletes an existing constraint group if the name matches the specified *constraint_group_name*. The default is false and the command exits with an error if the name already exists.

Feedback

Description

The *create_differential_group* command creates a constraint group for a collection of nets with differential_pair or differential_group intent. You must specify two or three nets with the *-for* option. When two nets are specified, the nets form a differential_pair. When three nets are specified, the nets form a differential_group. The constraint is used by Custom Router.

You can specify which layers are valid for the trunk routing and can also specify layer-specific spacing and width values. If one or more nets are shielded, the shielding placement of main trunk can also be specified.

You can specify how the nets in the differential_pair or differential_group can be twisted with the interval and offset.

Examples

The following example creates a constraint group with a system-generated name of "differential_pair_0" for nets prn and prp which will be of differential_pair intent. The twist style will be none and shield placement will be default. The 'prn' and 'prp' nets are routed with the Custom Router.

```
prompt> create_differential_group -for {prn prp}
{differential_pair_0}
```

The following example creates a constraint group with a system-generated name of "differential_group_1" for nets pr*. Assuming that there are three nets, the nets form a differential_group. The twist style will be none and shield placement will be interleave. A spacing of 3 will be used for layer M2 and spacing of 5 will be used for layer M3. The 'pr*' nets are routed with Custom Router.

```
prompt> create_differential_group -for pr* -shield_placement interleave
 \\
   -layer_spacings {M2 3 M3 5}
{differential_group_1}
```

---

create_diodes

Creates diodes to fix user-specified antenna violations.

Feedback

Syntax

status *create_diodes*

`-options list_of_violations`

Data Types

`list_of_violations` `list`

Arguments

`-options list_of_violations`

Specifies the antenna violations to be fixed by inserting diodes. You can specify one or more antenna violations. Each antenna violation is described by a list that contains the following elements:

- *port_name*

  Specifies the name of the port with the antenna violation.

- *block_instance_name*

  Specifies the name of the block instance with the antenna violation. For diode insertion on top-level ports, specify name of top design for this entry.

- *diode_frame_view_name*

  Specifies the name of the frame view of the diode to insert.

- *number_of_diodes*

  Specifies the number of diodes to insert.

- *max_routing_layer_name*

  Specifies the name of the maximum routing layer within which the diode should be connected to the antenna violating pin.

- *max_routing_distance*

  Specifies the maximum distance in microns along the route from the diode pin to the antenna violating pin.

Note: To use this command to insert diodes for top-level ports (terminals) and connect to them you must specify top design name for the *block_instance_name* entry.

This is a required argument.

Feedback

Description

This command inserts diodes to fix user-specified antenna violations. This command does not do any antenna analysis on the nets. It inserts the specified number of diodes and connects them. After this is done, it is assumed that the antenna violations are fixed. This command supports the use of spare diodes in the design. If a spare diode of the same frame view exists near the specified antenna port within the specified distance, it can be used to make a connection. This feature can be controlled with the *diode_insertion_mode* router detail route option. This command supports reuse of filler cell locations to insert diodes. It can be controlled using the *reuse_filler_locations_for_diodes* router detail route option. This command can be used to create new diodes or reuse diodes that are close to the antenna violating port. If the only legal location or spare diode is far off, the command cannot insert or reuse that diode or location. The distance up to which search is made is bounded by local area and is determined by the tool.

Other types of DRCs reported at the end of the command are not accurate. Run *check_routes* command to report those DRCs and detail route to fix them.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

This command creates diodes to fix user-specified antenna violations on the A port of the CI cell instance by using two diodes with a FRAM view of Adiode within the metal5 layer and within two microns of the port.

```
prompt> create_diodes -options {{A CI Adiode 2 metal5 2}}
```

This command creates diodes to fix two user-specified antenna violations.

```
prompt> create_diodes -options {{A CI Adiode 2 metal5 2}
   {B CI2 Bdiode 1 metal6 3}}
```

This command creates diodes for the ABC top-level port of a design with top cell name TCell.

```
prompt> create_diodes -options {{ABC TCell Adiode 2 metal5 2}}
```

---

create_drc_error

Creates a physical DRC error object.

Feedback

Syntax

```
collection create_drc_error
-error_data drc_error_data
-error_type drc_error_type
[-status error | fixed | ignored | waived]
[-polygons shape_list]
[-polylines shape_list]
[-endpoints coord_list]
[-points shape_list]
[-layers layers]
[-layer_names hierarchical_layer_names]
[-objects objects]
[-must_fix]
[-direction direction]
[-required_spacing distance]
[-actual_spacing distance]
[-width_required distance]
[-height_required distance]
[-shape_uses shape_uses]
[-pin_edge pin_edge]
[-information information]
```

Data Types

drc_error_data	collection
drc_error_type	collection
shape_list	list
coord_list	list
layers	collection
hierarchical_layer_names	string
objects	collection
direction	string
distance	float
shape_uses	list
pin_edge	integer
information	string

Arguments

`-error_data` *drc_error_data*

Specifies the error data in which to create the physical DRC error.

`-error_type` *drc_error_type*

Specifies the error type for which to create the physical DRC error. The error type value becomes available as the *error_type* attribute for the error.

`-status error | fixed | ignored | waived`

Sets the initial status of the new error. Available values are: *error, fixed, ignored,* and *waived*. If omitted, the status value *error* is used. The status value becomes available as the *status* attribute for the error.

Feedback

`-polygons` *`shape_list`*

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

`-polylines` *`shape_list`*

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polylines* attribute for the error.

`-endpoints` *`coord_list`*

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This option is a required option when create open error. The coordinates become available as the *endpoints* attribute for the error.

`-points` *`shape_list`*

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the *points* attribute for the error.

`-layers` *`layers`*

Specifies layers associated with the given shapes or coordinates. The layers are associated with the given shapes or coordinates. If more than one shape is required to describe the error and an exact association of shapes to layers is needed, provide one shape to the *create_drc_error* command and use the *create_drc_error_shapes* command to add the additional shapes with the associated layers. The layers become available as the *layers* attribute for the error. The option *-layers* and *-layer_names* are exclusive.

`-layer_names` *`hierarchical_layer_names`*

Specifies layers as hierarchical layer names that will be associated with the given shapes or coordinates. The layers are associated with the given shapes or coordinates. If more than one shape is required to describe the error and an exact association of shapes to layers is needed, provide one shape to the *create_drc_error* command and use the *create_drc_error_shapes* command to add the additional shapes with the associated layers. The layers become available as a collection from the *layers* attribute for the error if the hierarchical layer names are valid layers from the context of the top design. These layers are also available from the *layer_names* attribute for the error. The option *-layers* and *-layer_names* are exclusive.

Feedback

`-objects` *objects*

Specifies design objects associated with the new error. The objects become available as the *objects* attribute for the error.

`-must_fix`

Sets the *must fix* flag on the error. The default is false. The must fix value becomes available as the *must_fix* attribute for the error.

`-direction` *direction*

Sets the direction of a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The direction is used in rendering the spacing violation in the GUI layout view. The direction value becomes available as the *direction* attribute for the error.

`-required_spacing` *distance*

Sets the required spacing distance which was not met in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The required distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The required spacing value becomes available as the *required_spacing* attribute for the error.

`-actual_spacing` *distance*

Sets the actual spacing distance which did not meet requirements in a spacing violation. The option argument is ignored if the associated error type is not in the spacing class. The error class for the error type is set when it is created. The actual distance is used to provide a more detailed rendering of the spacing violation in the GUI layout view. The actual spacing value becomes available as the *actual_spacing* attribute for the error.

`-width_required` *distance*

Sets the required width of the drc_error object, which is the required width of the violating object. The required width has meaning in the context of a violation in the "size" error_class, where the width of the object does not meet the requirement.

`-height_required` *distance*

Sets the required height of the drc_error object, which is the required height of the violating object. The required height has meaning in the context of a violation in the "size" error_class, where the height of the object does not meet the requirement.

Feedback

`-shape_uses` *shape_uses*

Sets the shape uses associated with the error. The *shape_uses* values can be used to filter errors in the GUI error browser where the attribute is called "route types". The *shape_uses* become available as the *shape_uses* attribute for the error.

`-pin_edge` *pin_edge*

Sets the pin edge associated with the error. Given any shape, rectangular or rectilinear shape, the edge numbers are a list of positive integers that start from 1. The lower left-most vertical edge is the starting edge with side number 1. Going clockwise, the side numbers of the next edges are 2, 3, and so on. The pin edge is reported as a part of the detailed textual report in the GUI error browser. The pin edge value becomes available as the *pin_edge* attribute for the error.

`-information` *information*

Sets the error instance specific information string attribute. Information for an error instance is generally set by setting the brief_info and verbose_info attributes of the owning error type and formatting error instance specific data into these strings. However, there are times that information specific to an error instance must be set. In this case, use this attribute to set the information string.

Description

The *create_drc_error* command creates a physical DRC error object in the given error data for the given error type. Additional shapes with associated layers can be added to a drc_error object after creation by using the *create_drc_error_shapes* command.

Most of the attributes associated with a drc_error object are read-only and can only be set at the time of creation. Exceptions to this is the error status, which can be modified using the *set_attribute* command. All attribute values set at creation can then be accessed with the *get_attribute* command. In addition, the attribute values are displayed in the GUI error browser and the GUI layout view.

Brief and verbose information strings are accessible for each drc_error object as the *brief_info* and the *verbose_info* attributes, respectively. These strings are also displayed in the GUI error browser. These information strings are not attached to the drc_error object in the database but rather with the drc_error_type associated with the drc_error object. A message construction service customizes the information strings for each drc_error object by substituting attribute values from the drc_error object into the strings. A detailed description of the message construction is provided in the man page for *create_drc_error_type*.

Feedback

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the spacing class. A DRC error instance is then created for the new type.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \\
    -name "route spacing" -error_class spacing \\
    -required_objects {net net} \\
    -brief_info "A spacing violation between net %net:0% and net %net:1%
 was detected." \\
    -brief_format message \\
    -severity error]
{"route short"}

prompt> create_drc_error -error_data $data \\
    -error_type $type -objects [get_nets {"F_12_" "F_11_"}] \\
    -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200}
 {78.8600 186.3200}} \\
    -layers METAL -status error -direction vertical \\
    -required_spacing 3.400 -actual_spacing 31.400
{"123"}
```

- open_drc_error_data
- remove_drc_errors

---

create_drc_error_data

Creates an error data file and returns a collection that contains the error data object.

Syntax

```
collection create_drc_error_data
[-name name]
[-file_name file_name]
-checker_name checker_name
[-is_hier_tech_layer true | false]
[-checker_version version_string]
[-information info_string]
```

Feedback

Data Types

name	string
file_name	string
checker_name	string
version_string	string
info_string	string

Arguments

`-name` *name*

Specifies the name of the attached error data file to create. The error data file is attached to the current block.

The *-file* and *-file_name* options are mutually exclusive; you must specify one.

`-file_name` *file_name*

Specifies the name of the external error data file.

The naming convention for an error data file is to append an underscore, the checker name, and the ".err" suffix to the design name. For example, for a design named "my_design" and a checker named "test", the error data file name is named "my_design_test.err".

The *-file* and *-file_name* options are mutually exclusive; you must specify one.

`-checker_name` *checker_name*

Specifies the name of the rule checking engine creating the error data file.

For example, for the route check performed by the router, the engine name might be "zroute".

`-is_hier_tech_layer`

Specifies if the errors in this data will associate layers using strings corresponding to hierarchical layer names. By default, this is false and layer numbers from the technology are used. If this is set to true, use the "-layer_names" option in create_drc_error and create_drc_error_shapes to associate layers to errors.

`-checker_version` *version_string*

Specifies the version string for the checker engine.

`-information` *info_string*

Specifies an informative message to associate with the error data.

Feedback

Description

The *create_drc_error_data* command creates the specified error data file. The command fails if the specified error data file already exists.

If created with the *-name* option, the error data file is attached to the current block and is included in the block operation when the block is saved, copied, moved, and so on. To save an error data file created in this manner, run the *save_block* for the associated block.

If created with the *-file_name* option, the error data file is written to disk and is not attached to the current block. The error data file is not included in the block operation when it is saved, copied, moved, and so on. The created error data file is opened in read/write mode. To save an error data file created in this manner, run the *save_drc_error_data* command.

The command returns a collection that contains the error data object associated with the error data file. If no error data object is created, the command returns an empty string.

The *create_drc_error_data* command increments the open count for the error data object. The *create_drc_error_data* (and *open_drc_error_data*) commands must be balanced by an equal number of *close_drc_error_data* commands to close the error data object.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example creates an attached error data file named "dppinassgn.err", with a checker name of "dppinassgn", and a short information string.

```
prompt> set data [create_drc_error_data -name dppinassgn.err \\
   -checker_name dppinassgn \\
   -information "This error data contains pin assignment and \\
      placement errors for the my_design design"]
{"dppinassgn.err"}
```

The following example creates an external error data file named "my_design_dppinassgn.err", with a checker name of "dppinassgn", and a short information string.

```
prompt> set data [create_drc_error_data \\
   -file_name my_design_dppinassgn.err \\
   -checker_name dppinassgn \\
   -information "This error data contains pin assignment and \\
      placement errors for the my_design design"]
{"my_design_dppinassgn.err"}
```

---

create_drc_error_shapes

Creates shapes and layers and adds to a physical DRC error object.

Syntax

```
status create_drc_error_shapes
-error_data error_data
drc_error
[-polygons shape_list]
[-polylines shape_list]
[-endpoints coord_list]
[-points shape_list]
[-layers layers]
[-layer_names hierarchical_layer_names]
```

Data Types

error_data	collection
drc_error	collection
shape_list	list
coord_list	list
layers	collection
hierarchical_layer_names	string

Arguments

`-error_data error_data`

Specifies the error data in which to find the physical DRC error to modify.

drc_error

Specifies the error to which to add the shapes and layers.

Feedback

`-polygons` *`shape_list`*

Polygon or rectangle shapes which describe the DRC error. The *shape_list* argument is a list of shapes where each shape is a list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polygons* attribute for the error.

`-polylines` *`shape_list`*

Describes polylines shapes for DRC error. The *shape_list* argument is list of shapes where each shapes consist of list of x- and y-coordinate pairs: {{*x y*} {*x y*} {*x y*} {*x y*} ... }. The shapes become available as the *polylines* attribute for the error.

`-endpoints` *`coord_list`*

Specifies the two endpoints of distance shape of violation such as spacing or open error. The *coord_list* argument is a list of two x- and y-coordinate pairs: { {*x y*} {*x y*} }. If more than two points are given, only the first two are used and the rest are ignored. This option is a required option when create open error. The coordinates become available as the *endpoints* attribute for the error.

`-points` *`shape_list`*

Specifies points as shape of violation when necessary. The *shape_list* argument is a list of x- and y-coordinate pairs: { {*x y*} {*x y*} ... }. The coordinates become available as the *points* attribute for the error.

`-layers` *`layers`*

Specifies the layers associated with the given shapes or coordinates. The layers become associated with the given shapes. The option *-layers* and *-layer_names* are exclusive.

`-layer_names` *`hierarchical_layer_names`*

Specifies layers as hierarchical layer names that will be associated with the given shapes or coordinates. These layers become associated with the given shapes. The option *-layers* and *-layer_names* are exclusive.

Description

The *create_drc_error_shapes* command adds additional shapes and layers to an existing physical DRC error object in the given error data. Shapes and layers are added to the DRC error object at the time of creation. If more than one shape is required to describe the error and exact association of shapes to layers is needed, use the *create_drc_error_shapes* command to add the additional shapes with the associated layers. The layers become available as the *layers* attribute for the error. The command requires at least one of shape options be specified either using the *-layers* or *-layer_names* option. If *-layer_names* option is used, the layers become available as a collection from the *layers* attribute for the error if the hierarchical layer names are valid

Feedback

layers from the context of the top design. These hierarchical layer names will be available from the *layer_names* attribute for the error.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the basic class. A DRC error instance is then created for the new type. Additional shapes and layers are then added.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}

prompt> set type [create_drc_error_type -error_data $data \\
    -name "shapely error" -error_class basic \\
    -required_objects {net} \\
    -severity error]
{"route short"}

prompt> set error [create_drc_error -error_data $data \\
    -error_type $type -objects [get_nets {F_12_}] \\
    -polygons {{78.8600 189.4600} {79.8800 189.4600} {79.8800 186.3200}
 {78.8600 186.3200}} \\
    -layers METAL]
{"45"}

prompt> create_drc_error_shapes -error_data $data $error\\
    -polygons {{74.8600 189.4600} {75.8800 189.4600} {75.8800 186.3200}
 {74.8600 186.3200}} \\
    -layers METAL5
```

---

create_drc_error_type

Creates a physical DRC error type object.

Syntax

```
collection create_drc_error_type
-error_data drc_error_data
-name type_name
-error_class basic | spacing | short | open_locator
[-brief_info info_string]
```

Feedback

```
[-brief_format ascii | message]
[-verbose_info info_string]
[-verbose_format ascii | message]
[-severity error | information | recommendation | warning]
[-required_objects {layer net pin port cell pinGuide}]
[-num_detected_errors num_errors]
```

Data Types

```
drc_error_data      collection
type_name       string
info_string     string
num_errors      integer
```

Arguments

`-error_data drc_error_data`

Specifies the error data in which to create the physical DRC error type.

`-name type_name`

The name for the error type being created. Names must be unique in the scope of the owning error data.

`-error_class basic | spacing | short | open_locator`

Specifies the kind of errors represented by the new error type. The error class determines how the shapes of the associated DRC error instances are rendered in the GUI layout view. It also determines some expected attributes for its error instances. Available values are: basic, spacing, short, and open_locator.

The *basic* class allows its types to define required associated design objects. The *spacing* class allows its types to define required associated design objects and the error instances to describe a mismatch in actual and required spacing distance. Spacing errors can also be defined with a direction. The *short* class allows its types to define required associated design objects and is rendered with a diagonal cross inside of its shape. The *open_locator* class is for open nets and expects to be associated with a single net and to have two endpoints describing an open in a net as its shape description.

`-brief_info info_string`

Specifies a brief information string for display. Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The brief information string is expected to be a compact description that is suitable for display in a tabular format in the GUI error browser.

Feedback

`-brief_format ascii | message`

Specifies the display format of the brief information string specified with *-brief_info*. If the format is *ascii*, the brief info string is displayed exactly as specified with the *-brief_info* option, without modification. If the format is *message*, the brief info string is parsed for special tokens. The tokens are replaced with error instance attribute values before display.

`-verbose_info` *`info_string`*

Error instances of an error type are shown with brief and verbose information strings that are derived from the brief and verbose information strings associated with its error type. The strings can be customized for the error instance by using tokens that are replaced by the error instance's attribute values. See the DESCRIPTION section for a detailed explanation.

The verbose information string should be a detailed description that is suitable for display in a report format in the GUI error browser.

`-verbose_format ascii | message`

Specifies the display format of the verbose information string specified with *-verbose_info*. The format can be one of: *ascii* or *message*. If the format is *ascii*, the verbose info string is displayed exactly as specified with the *-verbose_info* option, without modification. If the format is *message*, then the verbose info string is parsed for special tokens. The tokens are replaced with error instance attribute value before display.

`-severity error | information | recommendation | warning`

Specifies the severity of the message associated with instances of this type.

`-required_objects {layer net pin port cell pinGuide}`

Specifies the required object classes associated with this error. A type might require that a specific number of design objects be associated with its error instances. For example, a route spacing type error might require that all of its instances have two associated nets. If the spacing violation is between shapes of the same net, the same net can be repeated twice. By specifying required objects, the type allows instances to be filtered for null object association.

The required objects are specified with a list of the design object class names. If multiple instances of a design object type are required, the class name can be repeated. For example, to specify that two nets are required, use the option argument *{net net}*.

While this option allows definition of the required design object types, additional objects can be associated with an error instance in addition to the required design object types.

Feedback

`-num_detected_errors` *num_errors*

Specifies the maximum number of detected errors that are allowed. Some checkers allow you to specify a limit on the number of errors detected per type. The checker can add information about how many errors were detected, vs. how many errors were added into the error database, by using this option.

Description

The *create_drc_error_type* command creates physical DRC error objects in the specified error data. Error types must have unique names in the scope of the owning error data and error types must be defined with an error class.

The command supports brief and verbose information strings for error type objects. These strings are displayed for each error instance in the GUI error browser. The strings can be customized with attribute values of an error instance by using the *message* format along with replacement of special tokens with attribute values.

A message construction service parses the error message for delimited tokens. If found, the command substitutes them with attribute values to construct a message appropriate for a specific DRC error instance. The token delimiter is the percent (%) character. To pass a percent symbol directly to the output message without modification, escape the character with a backslash: \\%. A token has the form *%<error instance attribute name[:<ordinal value>]>[.<attribute name>]%* Error instance attributes are named as described below.

For associated design objects, the attribute name is the object type name. If there are multiple objects of the same object type, the specific associated object is identified with the ":<ordinal value>" qualifier. The value starts at zero for the first identified object. For example "pin:0" identifies the first associated pin and "pin:2" identifies the third pin associated with the error instance. If the ordinal value qualifier is omitted, the first object of that type is default. The special character "*" can be used in place of the ordinal value to mean all objects of the given type. The supported object type names are: *layer, net, pin, port, cell,* and *pinGuide*.

In addition, the attribute name *type* can be used to denote the associated error type. Append a period character (.) delimiter to the optional attribute name to access a specific attribute for the identified object. If the attribute qualifier is omitted, the object's name is used. Attribute names supported with the associated object are: name and full_name. In addition, pin and port objects support the attribute name *cell* which will print the name of the cell associated with the pin or port. Attribute names supported with the associated error type are: name, severity, and class.

For other error instance attribute fields, access an attribute value by using the attribute name for the object. For example, use *actual* for the actual distance in a spacing violation and *direction* for the direction of a spacing violation. Some of these attributes can also be given with the *:<ordinal value>* qualifier. For example, there can be multiple route types associated with an error. As with design objects, if the ordinal value qualifier is omitted, the

Feedback

first one is selected by default. The * glob character can be used to specify all values. The currently supported error instance attributes are: *status, shapes, bbox, direction, actual, required, routeType,* and *endpoint*.

Examples

The following example opens a physical DRC error data file that is named "my_design_dppinassgn.err", then creates an error type in the short class.

```
prompt> set data [open_drc_error_data -file_name
 my_design_dppinassgn.err]
{"my_design_dppinassgn.err"}
prompt> create_drc_error_type -error_data $data \\
    -name "route short" -error_class short \\
    -required_objects {net net} \\
    -brief_info "A short between net %net:0% and net %net:1% was
 detected." \\
    -brief_format message \\
    -severity error
{"route short"}
```

---

create_drc_error_waiver

Creates a DRC error waiver object.

Syntax

```
collection create_drc_error_waiver
[-name name]
-filter expression
[-comment comment]
[-user user]
-container_name container
```

Data Types

```
name              string
expression        string
comment           string
user              string
container         string
```

Feedback

Arguments

`-name` *name*

Specifies the name of the error waiver to create.

`-filter` *expression*

Filters the collection with *expression*. For any physical DRC errors that match *patterns* the expression is evaluated based on the physical DRC error's attributes. If the expression evaluates to true, the status of physical DRC error included will be waived.

`-comment` *comment*

Specifies a comment or informative message to associate with the waiver.

`-user` *user*

Specifies the name of who create the waiver.

`-container_name` *container*

Specifies the waiver container for which to create the DRC error waiver.

Description

The *create_drc_error_waiver* command creates a DRC error waiver with a filter list for the given error waiver container.

The filter expression is used to waive matching physical DRC errors.

The waiver container supports different waivers being applied to different error databases.

Examples

The following example creates an error waiver container. A DRC error waiver is then created for the new waiver container.

```
prompt> set contain [create_waiver_container -name con1 \\
   -checker_name test
{con1}

prompt> create_drc_error_waiver -name w1 \\
    -container_name $con1 \\
    -filter {layers_name == METAL && type_name == "Off track pins"} \\
    -user Marry \\
    -comment "This is a new waiver to filter DRC errors"
{w1}
```

---

create_early_power_switch_cells

Creates an early power switch cells setup with a main net, virtual net, and a ground net for rail analysis.

Syntax

status *create_early_power_switch_cells*

```
-psw_conversion_factor psw_conversion_factor
-psw_ron_value psw_ron_value

-main_mesh main_mesh_spec
-psw psw_spec
-virtual_mesh virtual_mesh_spec
-ground_mesh ground_mesh_spec

[-virtual_mesh_exclude_region virtual_mesh_exclude_region]
[-ground_mesh_exclude_region ground_mesh_exclude_region]
[-psw_exclude_region psw_exclude_region]
```

Data Types

```
psw_conversion_factor       float
psw_ron_value               float

main_mesh_spec              string
psw_spec                    string
virtual_mesh_spec           string
ground_mesh_spec            string

virtual_mesh_exclude_region string
ground_mesh_exclude_region  string
psw_exclude_region          string
```

Arguments

`-psw_conversion_factor` *psw_conversion_factor*

Specifies the *psw_conversion_factor*.

Feedback

-psw_ron_value *psw_ron_value*

Specifies the *psw_ron_value* in Ohm.

-main_mesh *main_mesh_spec*

Specifies the *main_mesh_spec* in below syntax:

```
{
    {net: power_net}
     {{layer: metal_layer} {width: float} {xpitch: float}
 {ypitch: float} {xoffset: float} {yoffset: float}} | {{layer:
 via_layer} {via_cut_count: float}}
    ...
    {{layer: psw_pin_shape_layer} {psw_conn_count: float}
 {psw_pin_xoffset: float} {psw_pin_yoffset: float}}
}
```

-psw *psw_spec*

Specifies the *psw_spec* in below syntax:

```
{
    {xpitch: float} {ypitch: float} {xoffset: float}
 {yoffset: float}
}
```

-virtual_mesh *virtual_mesh_spec*

Specifies the *virtual_mesh_spec* in below syntax:

```
{
    {net: power_net}
    {{layer: metal_layer} {width: float} {xpitch: float}
 {ypitch: float} {xoffset: float} {yoffset: float}}
    ...
    {{layer: psw_pin_shape_layer} {psw_conn_count: float}
 {psw_pin_xoffset: float} {psw_pin_yoffset: float}}
}
```

-ground_mesh *ground_mesh_spec*

Specifies the *ground_mesh_spec* in below syntax:

```
{
    {net: ground_net}
    {{layer: metal_layer} {width: float} {xpitch: float}
 {ypitch: float} {xoffset: float} {yoffset: float}}
    ...
}
```

[-virtual_mesh_exclude_region *virtual_mesh_exclude_region*]

Specifies the *virtual_mesh_exclude_region* in below syntax:

```
{
{{layer: metal_layer} {bboxes: list_of_bboxes}}
    ...
}
```

Feedback

```
[-ground_mesh_exclude_region ground_mesh_exclude_region]

   Specifies the ground_mesh_exclude_region in below syntax:
   {
   {{layer: metal_layer} {bboxes: list_of_bboxes}}
       ...
   }

[-psw_exclude_region psw_exclude_region]

   Specifies the psw_exclude_region in below syntax:
   {
       {bboxes: list_of_bboxes}
       ...
   }
```

Description

Creates an early power switch cells setup with a main net, virtual net, and a ground net for rail analysis.

EXAMPLE

The following example creates an early power switch cells setup with a main net, virtual net, and a ground net.

```
# remove existing physical objects
prompt> change_selection [get_shapes *]
prompt> remove_physical_objects
prompt> change_selection [get_vias *]
prompt> remove_physical_objects
prompt> remove_cells -all

# configure per-layer routing direction
prompt> set ROUTING_LAYER_DIRECTION_OFFSET_LIST "{METAL4 horizontal}
 {METAL5 vertical}"
prompt> if {$ROUTING_LAYER_DIRECTION_OFFSET_LIST != ""} {
        foreach direction_offset_pair
 $ROUTING_LAYER_DIRECTION_OFFSET_LIST {
            set layer     [lindex $direction_offset_pair 0]
            set direction [lindex $direction_offset_pair 1]
            set offset    [lindex $direction_offset_pair 2]
            set_attribute [get_layers $layer] routing_direction
 $direction
            if {$offset != ""} {
                set_attribute [get_layers $layer] track_offset $offset
            }
        }
    }

# create ideal voltage points
prompt> remove_taps
```

Feedback

```
prompt> create_taps -of_objects [get_terminals {VDD VDD.extra1}]
 -supply_net VDD
prompt> create_taps -of_objects [get_terminals {VSS VSS.extra1}]
 -supply_net VSS

# create early power switch cells setup
prompt> reset_early_power_switch_cells
prompt> create_early_power_switch_cells
    -psw_conversion_factor 1
    -psw_ron_value 0.5

---

create_eco_bus_buffer_pattern

Creates an ECO bus buffer pattern.

Syntax

collection *create_eco_bus_buffer_pattern*

```
-name name
-first_buffer left | right | top | bottom
-measure_from left | right | top | bottom
[-distance length]
[-repeat_after number]
[-user_specified_distance length_list]
```

Feedback

Data Types

name	string
length	float
number	integer
length_list	list

Arguments

`-name` *name*

Specifies the name of the ECO bus buffer pattern to create. The name must be unique in a design.

`-first_buffer left | right | top | bottom`

Specifies the order in which the buffers are created. The order is relative to the location of the first buffer in the pattern. Buffer patterns for horizontal routes are specified by using *-first_buffer top* or *-first_buffer bottom*, and buffers are inserted on the route of the topmost or bottommost bit in the layout. Buffer patterns for vertical routes are specified by using *-first_buffer left* or *-first_buffer right*, and buffers are inserted on the route of the leftmost or rightmost bit in the layout.

`-measure_from left | right | top | bottom`

Specifies the side of the buffer to measure from when placing the next buffer in the pattern. Buffer patterns for horizontal routes are specified by using *-measure_from left* or *-measure_from right*. Buffer patterns for horizontal routes are specified by using *-measure_from top* or *-measure_from bottom*. The first buffer is placed at the reference side of the pattern, succeeding buffers are placed at the specified distance from the previous buffer in the opposite direction. For example, if you specify *-measure_from left* for a horizontal bus, the second buffer is placed to the right of the first buffer, the third buffer is placed to the right of the second buffer, and so on.

`-distance` *length*

Specifies the distance between the reference sides of two adjacent buffers. This option is mutually exclusive with the *-user_specified_distance* option and is used together with the *-repeat_after* option.

`-repeat_after` *number*

Restarts the pattern from the reference side after the specified *number* of buffers. If this option is not specified, the pattern continues and does not repeat. This option is mutually exclusive with the *-user_specified_distance* option and is used together with the *-distance* option.

Feedback

`-user_specified_distance` *`length_list`*

Specifies the distances between successive buffers. The first distance in the list is the distance between the reference sides of the first buffer and the second buffer. The second distance in the list is the distance between the reference sides of the second buffer and the third buffer, and so on. The pattern repeats after the last distance in the list is used, and the next buffer is placed at the reference side of the pattern again.

This option is mutually exclusive with the *-distance* and *-repeat_after* option.

Description

This command creates a buffer pattern with the specified placement edge, buffer-to-buffer placement distances, and pattern size. The command returns an ECO bus buffer pattern, which can be used with the *add_buffer_on_route -user_specified_bus_buffers* command.

Examples

The following example creates an ECO bus buffer pattern named bpLB. The first buffer is placed at the top left corner. Successive buffers are placed at a 2 micron pitch as measured from the left edge of the buffer. The pattern repeats from the left edge every eight buffers.

```
prompt> create_eco_bus_buffer_pattern -name bpLB \\
   -measure_from left -first_buffer top -distance 2 -repeat_after 8
```

The following example creates and ECO bus buffer pattern named bpMF. Distances between buffers are specified with the *-user_specified_distance* option. The pitch between the first buffer and second buffer is 2, the pitch between the second buffer and third buffer is 4, the pitch between the third buffer and fourth buffer is 1. The fifth buffer is placed at the left edge of the pattern.

```
prompt> create_eco_bus_buffer_pattern -name bpMF \\
   -measure_from left -first_buffer bottom \\
   -user_specified_distance {2 4 1}
```

Feedback

create_edit_group

Creates an edit group in the current design.

Syntax

collection *create_edit_group*

```
[-name edit_group_name]
[-ungroup_on_remove first | second-to-last | last | never]
[-group_use user | bump_array | macro_array | io_group]
[-cell cell]
```

Data Types

```
edit_group_name      string
cell                 collection
```

Arguments

`-name edit_group_name`

Specifies the name of the edit group.

By default, the command generates a name automatically. The command uses the prefix "EDIT_GROUP_" and appends a number in consecutive order, such as EDIT_GROUP_0, EDIT_GROUP_1, and so on.

`-ungroup_on_remove first | second-to-last | last | never`

Specifies when the edit group should be automatically removed from the design, depending on when objects in the edit group are removed. The *first* argument specifies that the edit group be removed when any member object is removed. The *second-to-last* or *last* arguments specify that the edit group be removed when the second-to-last or last member objects are removed, respectively. The *never* argument specifies that the edit group remain in the design even after all member objects are removed. By default, the *never* argument is used.

`-group_use user | bump_array | macro_array | io_group | structure`

Sets the use context of this edit group. The default is *user*.

`-cell cell`

Specifies the physical cell where the edit group is to be added. The edit group is created in the cell's reference block. The cell must reference a block, not a library cell, unless this command is executed in the library manager. In the library manager, edit groups can be created in library cells. When not specified, the edit group is created in the current block.

Feedback

Description

The *create_edit_group* command groups objects into a named collection. You can use the edit group to define a relative positioning constraint on a collection of objects, so that they are physically transformed in a consistent manner. Edit groups created using this command are containers which are initially empty. Objects can be added to edit groups with the *add_to_edit_group* command, and removed with the *remove_from_edit_group* command. An object can belong to only one edit group at a time. Removing an object from an edit group does not remove the object from the design, however removing an object from the design automatically removes it from its containing edit group. Edit group nesting is permitted, so edit groups can contain other edit groups as member objects.

This command returns the edit group as a single element collection, an empty string if it fails, or a Tcl error if there is a command syntax error.

Examples

The following example creates an edit group named "edit_group1", which is automatically removed when its last member object is removed.

```
prompt> create_edit_group -name "edit_group1" -ungroup_on_remove last
```

---

create_ems_database

Creates an EMS database and returns it in a collection.

Syntax

```
collection create_ems_database
ems_database_name
```

Data Types

```
ems_database_name  string
```

Feedback

Arguments

ems_database_name

Specifies the name for the EMS database to be created. The name should contain the ".ems" suffix.

Description

The *create_ems_database* command creates an EMS database and makes it the current EMS database. The *ems_database_name* argument must honor the naming convention and end with ".ems", such as "cts.ems", "check_design.ems", and so on. Use the *save_ems_database* command after *create_ems_database* to write out the database to disk. The created EMS database name is returned in a collection.

Examples

The following example creates an EMS database named a.ems and makes it the current EMS database.

```
prompt> create_ems_database a.ems
{a.ems}
prompt> get_current_ems_database
{a.ems}
```

The following example shows the error you receive if you omit the .ems extension.

```
prompt> create_ems_database abc
Error: Illegal EMS filename. Filename needs to have suffix of
 '.ems' (EMS-004)
```

The following example shows the error you receive if you try to create an EMS database that already exists.

```
prompt> create_ems_database a.ems
Error: file 'a.ems" already exists. It cannot be created. (EMS-032)
```

Feedback

create_ems_message

Creates an EMS message for user-defined EMS rule

Syntax

string *create_ems_message*

```
-rule rule_name
[-parameters parameter_values]
```

Data Types

```
rule_name        string
parameter_values string
```

Arguments

`-rule rule_name`

Specifies the name of the user-defined rule for which the EMS message needs to be created. This is a mandatory option. If the rule name is invalid or if it does not match any existing user-defined rule name then an error message is displayed.

`-parameters parameter_values`

Specifies the values for the EMS parameters defined in the EMS rule. This is an optional option. The argument is a list of strings, which is a sequence of one or more pairs, where each pair is of the format <parameter_name>:<parameter_value>. All the parameters defined in EMS rule should be provided with a value, or else the creation of EMS message fails and command returns an error message.

Description

The *create_ems_message* command creates an EMS message using the user-defined EMS rule name. Before invoking this command, you should have a current EMS database in memory. If one does not exist then it can be created using the *create_ems_database* command. This command also takes the values for parameters present in user-defined EMS rule.

Examples

```
prompt> create_ems_rule -name "TEMP-001" -severity "Info" \\
   -message "Pin:%pin has capacitance:%cap" \\
   -parameters "name:pin type:string command:get_pins ; name:cap
 type:double"
prompt> create_ems_rule -name "TEMP-002" -severity "Error" \\
   -message "Cell %cell is not placed" \\
   -parameters "name:cell type:string command:get_cells"
```

Feedback

```
prompt> create_ems_rule -name "DUMMY-001" -severity "Warning" \\
   -message "This is a dummy warning message without parameters"
prompt> create_ems_database a.ems
{a.ems}
prompt> set cap 0.0004
prompt> create_ems_message -rule "TEMP-001" \\
   -parameters "pin:U1/I cap:$cap"
prompt> set cell U23
prompt> create_ems_message -rule "TEMP-002" -parameters "cell:$cell"
prompt> create_ems_message -rule "DUMMY-001"
prompt> report_ems_database
 ...
Information: Pin:U1/I has capacitance 0.0004 (TEMP-001)
Error: Cell U23 is not placed (TEMP-002)
Warning: This is a dummy warning message without parameters (DUMMY-001)
```

See Also

- create_ems_database
- create_ems_rule

---

create_ems_rule

Creates a user-defined EMS rule. An EMS rule is a template used to create EMS messages.

Syntax

```
create_ems_rule
-name        rule_name
-severity    rule_severity
-message     message_template
[-parameters parameter_properties]
```

Data Types

```
rule_name            string
rule_severity        string
message_template     string
parameter_properties string
```

Arguments

`-name rule_name`

Specifies the name used to uniquely identify this rule. This is a mandatory option. If a rule by this name already exists in EMS memory, then an error message will be displayed. The rule name should obey the regular expression [A-Z]+[-][0-9]+ i.e one or more upper-case letters, followed by hyphen character

Feedback

and which should be followed by one or more numerals. If rule name does not obey this regular expression, then an error message is displayed. The sub-string in the rule name before hyphen character is called the *domain* name. If there are many rules which are closely associated with each other then it is advised to choose the same *domain* name.

`-severity` *`rule_severity`*

Specifies whether the rule corresponds to an error, warning, or information. This is a required option. The valid values are *error*, *information*, *info*, *warning*, *warn*, *fatal* and *serror*. These string values can be in upper or lower case or a mix of both. But it is advisable to stick to one convention for the sake of uniformity. But when the EMS message is displayed in the shell or in the EMS GUI message browser, the severity string displayed will be one of *Error*, *Warning*, *Information*, *Fatal* or *Serror*.

`-message` *`message_template`*

Specifies the message template for the rule. This is a mandatory option. The message template can contain placeholders referred to as *parameters*. Parameters begin with a *%* character. The parameter name should obey regular expression [A-Za-z0-9_]+ i.e it should contain one or more of upper or lower case alphabets or numerals or underscore character. There should not be any whitespace between *%* and parameter name. If user wants to use literal *%* the she should use *%%*.

`-parameters` *`parameter_properties`*

Specifies the parameter properties for the rule. This is an optional option. If there are no EMS parameters for the rule being defined, then this option is not required. But if there are EMS parameters specified in message template, this option can be used to define the parameter properties. This option takes a string as an argument which contains groups of name-value pairs fields separated by a semi-colon (;). Each group describes properties of an EMS parameter, which again is a sequence of pairs of format <name>:<value>.

Currently, an EMS parameter can have at-most three properties: name-property, type-property and command-property. Here type-property and command-property are optional and name-property is mandatory. name-property will take a valid parameter name as value and which helps EMS to know properties of which parameter are defined. type-property can take one of *string*, *int*, *float* and *double* values. type-property is used to define the type of the EMS parameter. The command-property of the EMS parameter can take value as any of the *get_** commands such as *get_pins*, *get_cells*, and so on, which take an object name as argument and return the object handle. This property is used to get the object handle corresponding to the EMS parameter name.

Feedback

Description

The *create_ems_rule* command creates a user-defined EMS rule. An EMS rule is a message template with some auxiliary information used to create the EMS message. The user-defined rules created are not persistent across sessions.

Examples

```
prompt> create_ems_rule -name "TEMP-001" -severity "Info" \\
   -message "Pin:%pin has capacitance:%cap" \\
   -parameters "name:pin type:string command:get_pins ; name:cap
 type:double"
prompt> create_ems_rule -name "TEMP-002" -severity "Error" \\
   -message "Cell %cell is not placed" \\
   -parameters "name:cell type:string command:get_cells"
prompt> create_ems_rule -name "DUMMY-001" -severity "Warning" \\
   -message "This is a dummy warning message without parameters"
prompt> create_ems_database a.ems
{a.ems}
prompt> set cap 0.0004
prompt> create_ems_message -rule "TEMP-001" \\
   -parameters "pin:U1/I cap:$cap"
prompt> set cell U23
prompt> create_ems_message -rule "TEMP-002" -parameters "cell:$cell"
prompt> create_ems_message -rule "DUMMY-001"
prompt> report_ems_database
 ...
Information: Pin:U1/I has capacitance 0.0004 (TEMP-001)
Error: Cell U23 is not placed (TEMP-002)
Warning: This is a dummy warning message without parameters (DUMMY-001)
```

---

create_environment

Create environment needed to run run_library_analysis

Syntax

status *create_environment*

```
-name string
-libset libset_name |
[-op_conds op_cond_names]
[-ppvt list_of_ppvt]
[-slew_points Slew characterization points]
[-load_points Load characterization points]
```

Feedback

```
[-std_load_points Standard load characterization points]
[-corners corner_names]
[-auto_infer_design auto infer ppvt from design]
```

Data Types

```
name string
libset string
op_conds  list
ppvt  list
slew_points list
load_points list
std_load_points list
corner_names            list
auto_infer_design boolean
```

Arguments

`-name`

The name for the new environment being created.

`-libset`

The name of the libset to which this environment will apply to.

`-op_conds`

The list of names for the operating conditions to use for analysis. Use -ppvt option for better control of PPVT

`-ppvt`

The list of ppvt to be used to create an environment. It is a list of quadruple which contains process label, process number, voltage and temperature. A process label none will need to be passed if there is no label.

`-slew_points`

The slew points to use for analysis

`-load_points`

The load points to use for analysis in user capacitance units. Exclusive of the -std_load_points option.

`-std_load_points`

The load points to use for analysis expressed in multiples of the standard load. Exclusive of the -load_points option

`-corners corner_names`

Specifies the list of corner names from which the ppvt values can be infered automatically.

Feedback

`-auto_infer_design`

Automatically infers the ppvt values from the scenario and UPF associated with the current design

Description

The create_environment command creates an environment that is needed to run run_library_analysis.

if the -op_conds option is used, then the operating condition name should correspond to the same process, voltage, temperature in all libraries. This option is for backward compatibility only. It is recommended to use -ppvt option.

The process label, process number, voltage and temperature for the quadruple is the same as the one that is passed to set_process_label, set_process_number, set_voltage and set_temperature command respectively.

When the -corners option is used, then the process label, process number, voltage and temperature will be inferred from the corners.

When the -auto_infer_design option is used, then the process label, process number, voltage and temperature will be inferred from the corners and supply voltage information provided in UPF.

The current design needs to be defined for the -corners and -auto_infer_design options to work.

The -slew_points can be used to specify the exact value of slew to use during analysis.

The -load_points can be used to specify the exact values of load points to use during analysis

The -std_load_points can be used to specify the values of load points to use during analysis. The input cap of the characteristic/smallest inverter is multiplied to each of the load points.

If none of -slew_points, -load_points, or -std_load_points are specified, then the default value is used. By default, the smallest area and leakage inverter in the libset is used for input slew and output load if none is specified. An output load of 4 times the input pin cap of the characteristic inverter is used for the characteristic output load, and a single input slew equal to the output slew of the inverter driving 4 copies of itself.

Examples of using the command:

```
create_libset -name libset -libs [get_lib *]
create_environment -name env1 -libset libset -ppvt {{ssgnp0p675v125c,
0.999998, 0.675, 125.00}}
create_environment -name env2 -libset tcbn45 -ppvt { {"(none), 1.0, 0.99,
 125"} {"(none), 1.0, 0.99, -40"} }
```

Feedback

```
create_environment -name env3 -libset tcbn45 -auto_infer_design
create_environment -name env4 -libset tcbn45 -corners nworst
```

create_expression_statement

Creates 1 RTL expression statement.

Syntax

collection *create_expression_statement*

```
-list_members list_members | -literal_text literal_text |
 -operation operation  -operands operands
[-scope scope]
-module module | -cell cell
```

Data Types

```
list_members        collection
literal_text        string
operation           string
operands            collection
module              collection
cell                collection
scope               collection
```

Feedback

Arguments

`-list_members` *list_members*

Creates a list type expression statement. This option is mutually exclusive with the *-operation* and *-literal* options. The list members must be specified with this option. Each list member can be an RTL variable, net, port, busNet, or busPort.

`-literal_text` *literal_text*

Creates a literal type expression statement. This option is mutually exclusive with the *-operation* and *-literal* options. The specified literal text must be in string format.

`-operation` *operation*

This is mutually exclusive with -literal and -list. With this option we need to give list of operands also.

`-operands` *operands*

Specifies the list of operands for the expression. Each operand can be an RTL variable, RTL literal, RTL list, RTL expression, net, port, busNet, or busPort.

`-module` *module*

Specifies the module to create the expression statement in. This option is mutually exclusive with the *-cell* option.

`-cell` *cell*

Specifies the cell to create the expression statement in. This option is mutually exclusive with the *-module* option.

`-scope` *scope*

Adds the newly created expression statement in the scope provided by the RTL statement.

Description

This command creates an expression object representing an expression statement in the RTL. The expression statement is created in the specified module or cell.

Examples

The following example creates 1 expression statement in the given cell doing addition(+) of 2 variable statements rtlVar_var1 and rtlVar_var2.

```
prompt> create_expression_statement -operation + {u1/u1/rtlVar_var1
 u1/u1/rtlVar_var2} \\
   -cell u1/u1 \\
   {"u1/u1/RTL_EXPRESSION_85"}
```

Feedback

---

create_exterior_tap_walls

Creates a tap wall at a specified distance outside a boundary edge of a core area, hard macro, soft macro, or hard placement blockage.

Syntax

status *create_exterior_tap_walls*

```
-lib_cell cell_name
-bbox  coordinates
-side  top | bottom | left | right
[-x_margin distance]
[-y_margin distance]
[-prefix cell_prefix]
[-orientation cell_orientation]
```

Data Types

```
cell_name        string
coordinates      list
distance         float
cell_prefix      string
cell_orientation     string
```

Arguments

`-lib_cell cell_name`

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

`-bbox coordinates`

Specifies the rectangular tap insertion region in microns. Specify the rectangle as a list of four coordinates, {{llx lly} {urx ury}}, which represents the lower-left and upper-right corners of the rectangle.

A tap wall is created along the longest edge of the core boundary, macro, or hard placement blockage encompassed by the rectangular region. The command issues an error message if it cannot find an edge.

This is a required option.

Feedback

`-side top | bottom | left | right`

Specifies the side on which to create a tap wall. You must specify a single side. This is a required option.

`-x_margin` *`distance`*

Specifies the margin in microns of a horizontal tap wall.

The default is 0.

`-y_margin` *`distance`*

Specifies the margin in microns of a vertical tap wall.

The default is 0.

`-prefix` *`cell_prefix`*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

`<cell_prefix>__<lib_cell>_R#_C#_number`

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

`extTapWall__<`*`lib_cell`*`>_R#_C#_`*`number`*

`-orientation` *`cell_orientation`*

Specifies the orientation of the placement of the tap cells. The valid values are: R0, R90, R180, R270, MX, MXR90, MY, MYR90.

The default is R0.

Description

This command adds an exterior tap wall to the design. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cells in the library do not contain substrate or well taps.

Exterior tap wall placement does not honor standard cell rows or sites and does not cross the object's boundary. Only one edge of the specified side is be processed in each command execution. If the tap insertion region spans multiple edges, only the longest edge is processed. If the tap insesrtion region does not contain an edge, the command issues an error message.

The tap cells are inserted within the tap insertion region, including the specified margins. A horizontal tap wall starts at the x-margin from the left of the bounding box. A vertical tap

Feedback

wall starts at the y-margin from the bottom of the bounding box. If the tap insertion region, including the margins is too small, the command does not insert tap cells.

You must ensure that the tap insertion region is empty. Otherwise, the inserted tap wall might overlap macros or other cells.

The command marks the inserted tap cells as fixed.

Examples

The following example creates tap walls outside the longest edge on the bottom of the core area.

```
prompt> create_exterior_tap_walls -lib_cell myLib/Cell1 \\
   -side bottom -bbox {{-20 -20} {20 200}}
```

---

create_failsafe_fsm_group

Creates one failsafe FSM group.

Syntax

status *create_failsafe_fsm_group*

```
[-rule failsafe_fsm_rule]
[-name group_name]
[-registers pins]
[-parity pins]
[-synchronizer pins]
[-error_signal pin_or_port]
[-taps cells]
[-correction_signal pin_or_port]
[-encoder cell]
[-decoder cell]
[-requirement_id requirement_id]
[-update]
[-split_pins pins]
```

Data Types

```
failsafe_fsm_rule  collection
group_name         string
```

Feedback

```
pins                collection
pin_or_port         collection
cells               collection
cell                collection
requirement_id      string
pins                collection
```

Arguments

`-rule` *failsafe_fsm_rule*

Specifies the failsafe FSM rule, based on which this failsafe FSM group should be created. This is mandatory, if the *-update* option is not specified.

`-name` *group_name*

Specifies the name of the new failsafe FSM group. If not specified, the name is automatically generated by the tool.

`-registers` *pins*

Specifies the collection of register output pins, which is part of the failsafe FSM group. This is mandatory, if the *-update* option is not specified.

`-parity` *pins*

Specifies the collection of output pins of registers, which are parity registers for the failsafe FSM group. This is mandatory, if the *-update* option is not specified.

`-synchronizer` *pins*

Specifies the collection of output pins of registers, which are the synchronizer registers for the failsafe FSM group.

`-error_signal` *pin_or_port*

Specifies an existing pin or port in the design to which the error signal generated from the failsafe finite state machine logic should be tied. Either a hierarchical or leaf-level pin or an output port can be specified, but it must exist in the design. This is mandatory for the rules of encoding type *hamming2*. It cannot be specified for the rules of encoding type *hamming3*.

`-taps` *cells*

Specifies the collection of tap cells for this group.

`-correction_signal` *pin_or_port*

Specifies the pin or port in the design where all the correction outputs are connected to. Either a hierarchical or top-level port or input pin of leaf-level cell can be specified, but it must exist in the design. This is optional. It cannot be specified for rules of encoding type *hamming2*.

Feedback

`-encoder` *cell*

Specifies the hierarchical or leaf-level cell, which is the encoder logic for this group. This is optional.

`-decoder` *cell*

Specifies the hierarchical or leaf-level cell which is the decoder logic for this group. This is optional.

`-requirement_id` *requirement_id*

Specifies the requirement Id string for tracking in requirement management system. The requirement Id string should only contains either alphanumeric, underscore or hyphen characters.

`-update`

Specifies that the existing failsafe_fsm_group that needs to be updated. The *-name* must be specified and the group with that name must exist.

The following attributes of the group can be updated: *synchronizer*, *taps*, *error_signal*, *correction_signal*, *encoder*, *decoder*, *requirement_id* and *split_pins*.

This option is mutually exclusive with the *-rule*, *-registers* and *-parity* options.

`-split_pins` *pins*

Specifies the set of pins, which should be split to be a part of different branches of high-fanout tree. This is optional.

Description

This command creates one failsafe FSM group object based on the given parameters. It stores the reference to the original failsafe FSM rule, which was honored to create it. This command supports undo or redo operations.

This command is primarily used for manually created failsafe finite state machines. You can manually create failsafe finite state machines in the design and mark them appropriately for further analysis down the flow.

You can choose two different approaches for this: RTL based flow, and Netlist based flow.

For both the flows, ensure that failsafe finite state machine has been already synthesized. In RTL based flow, the synchronizer and parity registers can be included in the RTL itself. After linking the design using *set_top_module* command, the *create_failsafe_fsm_group* command can be used, and these registers can be specified with it. In other words, the failsafe finite state machine should be implemented at RTL level. In the netlist based flow, you can start with a design, where finite state machines are present (this can be verified by running *report_rtl* command first). Note that netlist creation using *read_verilog* does not work for this flow, since the RTL must go through *analyze* and *elaborate* steps to process the finite state machines. You can instantiate the synchronizer and parity registers

Feedback

manually using a command such as *create_cell* and manually perform the encoding and connections in the netlist. After that, *create_failsafe_fsm_group* can be called to mark it as a failsafe finite state machine.

Examples

The following example creates a failsafe FSM group consisting of three registers, a correction signal and requirement Id:

```
prompt> create_failsafe_fsm_group -rule rule1 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -correction_signal {correction_port} \\
    -requirement_id cff_group-1 -name group1
```

The following example creates a failsafe FSM group with synchronizer and error_signal:

```
prompt> create_failsafe_fsm_group -rule rule2 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -synchronizer {flop5/Q} -error_signal {err_port}
    -name group2
```

The following example creates a failsafe FSM group consisting of tap cells and split_pins:

```
prompt> create_failsafe_fsm_group -rule rule3 \\
    -registers {flop1/Q flop2/Q flop3/Q} -parity {flop4/Q} \\
    -taps {TAP1 TAP2} -split_pins {flop1/pin1 flop2/pin2} -name group3
```

The following example updates the taps and error_signal attributes of existing failsafe_fsm_group group3.

```
prompt> create_safety_error_code_group -update -name group3 \\
    -taps {TAP3 TAP4} -error_signal err_blk/IN1
```

- remove_failsafe_fsm_groups
- report_failsafe_fsm_groups

---

create_failsafe_fsm_rule

Creates one failsafe fsm rule.

Syntax

status *create_failsafe_fsm_rule*

```
[-name rule_name]
[-encoding_style name]
```

Feedback

```
[-isolation]
[-update]
[-error_detection_synchronizer]
[-tap_mapping lib_cell_list]
[-distance values]
[-split_pin_types pin_type_list]
```

Data Types

rule_name	string
name	string
lib_cell_list	collection
values	list
pin_type_list	list

Arguments

`-name` *rule_name*

Specifies the name of the rule to be created. If not specified, a name is automatically generated and assigned.

`-encoding_style` *name*

Specifies the encoding style of the failsafe finite state machine. Valid values are *hamming2* and *hamming3*.

`-isolation`

Specifies that the failsafe finite state machine needs isolation using appropriate tap cell insertion.

`-update`

Specifies that the existing failsafe finite state machine needs to be updated. You must specify the *-name* and the rule with that name must exist.

The following attributes of the rule can be updated: *encoding_style*, *tap_mapping*, *isolation*, *-error_detection_synchronizer*, *-distance* and *-split_pin_types*.

`-error_detection_synchronizer`

Specifies if a synchronizing register needs to be added on the error signal. This option must be specified with *-encoding_style hamming2*. This option is mutually exclusive with *-encoding_style hamming3*.

`-tap_mapping` *lib_cell_list*

Specifies the list of library cells, out of which the appropriate one is used for instantiating tap cells for the failsafe fsm.

Feedback

`-distance` *values*

Specifies the minimum distance by which the registers of a failsafe fsm group need to be separated from each other after placement. It can either be in the form of an {x y} pair or a single number denoting radial distance. The values are in user units and cannot be negative. The distances are measured edge-to-edge, or in other words, from the boundary of one register to the closest boundary of another.

Specifying the {x y} distance pair means that either "x" or "y" separation must be honored. In other words, each pair of registers in the group should be either "x" distance apart measured on x-axis, or "y" distance apart measured on y-axis. This effectively creates a rectangular keep-out region around each register, in which it is forbidden to place another register of the same group. It is allowed to specify a distance of zero for either "x" or "y", but not for both simultaneously.

Specifying the single "r" value means that the Manhattan distance between each pair of registers in the group should be at least "r". The Manhattan distance between two registers is defined as the sum of the vertical distance and horizontal distance between their closest edges. Specifying a radial distance thus creates an octagonal keep-out region around each register, wherein another register of the same group must not be placed. For cells in the same column, the horizontal distance is 0. For cells in the same row, the vertical distance is 0. This "r" value cannot be zero.

This is optional.

`-split_pin_types` *pin_type_list*

Specifies the pin types, which should be considered for splitting to be a part of different branches of clock tree or high-fanout net trees. Valid values are *clock*, *reset*, and *scan*. You can specify the list of one or more valid types. This is optional.

Description

This command creates a new failsafe fsm rule, based on the specified options . This rule can be then used by the tool to implement failsafe finite state machines automatically based on the specified encoding style.

Examples

The following example creates a simple failsafe fsm rule with hamming2 encoding and library cells C and D of tap cells.

```
prompt> create_failsafe_fsm_rule -encoding_style hamming2 -name rule1 \\
        -error_detection_synchronizer -tap_mapping [get_lib_cells {C D}]
```

Feedback

The following example defines a rule that requires isolation:

```
prompt> create_failsafe_fsm_rule -encoding_style hamming3 -name rule2
 -isolation
```

The following example updates the tap_mapping attribute of existing failsafe_fsm_rule rule2.

```
prompt>  create_failsafe_fsm_rule -name rule2 -update \\
    -tap_mapping TAP_LIB_CELL
```

The following example creates failsafe_fsm_rule rule3 with distance as {1 2} and split_pin_types as scan and reset.

```
prompt>  create_failsafe_fsm_rule -name rule3 \\
    -split_pin_types {scan reset} \\
    -distance {1 2}
```

---

create_feature_table

Creates feature table for the specified objects.

Syntax

create_feature_table

```
-table table_name
-objects collection_of_objects
-features list_of_feature_names]
[-function extract_proc_name]
[-type feature_type]
[-labels feature_name_pairs]
[-index index_feature_name]
[-index_function index_proc_name]
[-keep_all_features]
```

Data Types

table_name	string
collection_of_objects	collection

Feedback

```
list_of_feature_names                list
extract_proc_name                    string
feature_type                         string
feature_name_pairs                   list
index_feature_name                   string
index_proc_name                      string
```

Arguments

`-table` *table_name*

Specifies the name of the feature table to be created. You cannot use an existing table name.

`-objects` *collection_of_objects*

Specifies the objects to be used to create the feature table. Each object is created as one row in the feature table.

The objects can be any object class if they are in a collection. For example, cell collection, net collection, and so on.

`-features` *list_of_feature_names*

Specifies the features to be extracted. The feature can be: 1. predefined feature (attribute of the objects) 2. user-defined feature

For user-defined feature, use *-function* option to define how to extract data as the user-defined feature value, and use *-type* option to indicate the data type.

`-function` *extract_proc_name*

Specifies the Tcl proc to be used to extract user-defined feature.

The Tcl proc takes object and feature name as parameters, and return user-defined feature value. The proc returns empty string if it fails to extract user-defined feature. Empty string is converted to nan as default value internally.

Example user-defined proc:

```
proc my_extract {object feature_name} {
  if {$feature_name == "test1"} {
    return 123
  } elseif {$feature_name == "test2"} {
    return {1 2 3}
  } elseif {$feature_name == "test3"} {
    return {{1 2} {3 4}}
  } elseif {$feature_name == "test4"} {
    return {{1 2} {a b}}
  } else {
    return ""
  }
}
```

Feedback

`-type` *`feature_type`*

Specifies the data type of the user-defined feature. You must use this option with *-function* option. The valid values for "type" are:

```
int
double
float
bool
string
list
dict
```

The feature data is converted to data of corresponding type.

This option is optional. If this option is not specified, this command automatically infers the data type, except for dict, bool.

`-labels` *`feature_name_pairs`*

This option is used to change the feature names. Specify the label in the format {{orig_name1 new_name1} {orig_name2 new_name2} ...}

`-index` *`index_feature_name`*

By default, this command uses "full_name" as index. This option is used to specify other feature as index.

The index feature can be: 1. predefined feature (attribute of the objects) 2. user-defined feature

For user-defined feature, use *-index_function* to define how to extract data as user-defined index feature value.

The index data type is converted automatically. If the data can be converted to integer, the index is integer, otherwise, the index is be converted to string.

`-index_function` *`index_proc_name`*

Specifies the Tcl proc to be used to extract user-defined index feature. You must use this option with the *-index* option.

The Tcl proc takes object and index name as parameters, and return user-defined feature value. The proc must not return empty value.

Example user-defined proc:

```
proc my_index_extract {object index_name} {
  if {$index_name == "index1"} {
    return 123
  } elseif {$index_name == "index2"} {
    return "my_[get_attribute $object name]"
  } else {
    return "index"
```

Feedback

```
    }
  }
```

`-keep_all_features`

By default, this command ignores: 1. feature column if all objects fail to get this feature 2. object row if this object fails to get any feature

If this option is specified, this command keeps the columns or rows mentioned previously, and fills nan for the missing values.

Description

This command creates a feature table with the specified table name and features. The features can be predefined features or user-defined features.

Examples

The following example shows the command creates a feature table with predefined features.

```
prompt> create_feature_table -table "my_table" -objects $cells \\
   -features {width height area}
```

The following example shows the command creates a feature table with user-defined features.

```
prompt> proc my_extract {object feature_name} { \\
      if {$feature_name == "test_feature"} { \\
        return 123 \\
      } else { \\
        return "" \\
      } \\
    }

prompt> create_feature_table -table "my_table" -objects $cells \\
   -features {test_feature} -function my_extract -type int
```

The following example shows the command creates a feature table with predefined index feature.

```
prompt> create_feature_table -table "my_table" -objects $cells \\
   -features {width height area} -index object_id
```

The following example shows the command creates a feature table with user-defined index feature.

```
prompt> proc my_index_extract {object index_name} { \\
      if {$index_name == "test_index"} { \\
        return [get_attribute $object object_id] \\
      } \\
    }
```

Feedback

```
prompt> create_feature_table -table "my_table" -objects $cells \\
   -features {width height area} \\
   -index test_index -index_function my_index_extract
```

The following example shows the command creates a feature table with feature names remapped.

```
prompt> create_feature_table -table "my_table" -objects $cells \\
   -features {width height area} \\
   -labels {{width x_len} {height y_len}}
```

---

create_fill_cell

Creates a new fill cell in the current block.

Syntax

```
status create_fill_cell
   -reference reference
```

Data Types

reference string

Arguments

-reference reference

Name of the internal design in this or another design.

Description

Creates a new fill cell in the current block using the specified reference. The specified reference, must be an internal design. If the specified reference is an internal design from another design, it is copied as an internal design in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example creates a fill cell, using internal design "m1_fill" from design "myDesign" as reference.

```
prompt> create_fill_cell -create_reference myDesign.m1_fill.design
2
```

See Also

---

create_for_statement

Creates 1 RTL for statement.

Syntax

collection *create_for_statement*

```
-init init
-next next
-test test
-statement statement
[-module module | -cell cell]
[-scope scope]
```

Data Types

init	collection
next	collection
test	collection
statement	collection
module	collection
cell	collection
scope	collection

Arguments

`-init init`

Specifies the type assignment used as the initialization statement for the RTL for statement.

`-next next`

Specifies the type assignment used as the next statement for the RTL for statement.

Feedback

`-test` *test*

Specifies the type expression used as the test statement for the for statement.

`-statement` *statement*

Specifies the statement for the RTL for statement.

`-module` *module*

Specifies the module to create the for statement in. This option is mutually exclusive with the *-cell* option.

`-cell` *cell*

Specifies the cell to create the for statement in. This option is mutually exclusive with the *-module* option.

`-scope` *scope*

Adds the newly created for statement in the scope provided by the RTL statement.

Description

This command creates an RTL for statement. The for statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the for statement is created in the current instance.

Examples

The following example creates 1 for statement in the given instance with the literal statement named *RTL_LITERAL_2*, the init statement named *RTL_ASSIGNMENT_7*, the next statement named *RTL_ASSIGNMENT_14*, and the test expression named *RTL_EXPRESSION_8*.

```
prompt> create_for_statement \\
   -statement [get_statements u1/u1/RTL_LITERAL_2 ] \\
   -init [get_statements u1/u1/RTL_ASSIGNMENT_7] \\
   -next [get_statements u1/u1/RTL_ASSIGNMENT_14] \\
   -test [get_statements u1/u1/RTL_EXPRESSION_8] \\
   -cell u1/u1 {"u1/u1/RTL_FOR_85"}
```

See Also

- get_statements
- remove_statements

---

create_foreach_statement

Creates 1 RTL foreach statement.

Feedback

Syntax

collection *create_foreach_statement*

```
-expression expression
-statement statement
[-module module | -cell cell]
[-scope scope]
```

Data Types

```
expression          collection
statement           collection
module              collection
cell                collection
scope               collection
```

Arguments

`-expression expression`

Specifies the RTL statement expression type for the foreach statement.

`-statement statement`

Specifies the statement used for the RTL foreach statement.

`-module module`

Specifies the module to create the foreach statement in. This option is mutually exclusive with the *-cell* option.

`-cell cell`

Specifies the cell to create the foreach statement in. This option is mutually exclusive with the *-module* option.

`-scope scope`

Adds the newly created foreach statement in the scope provided by the RTL statement.

Description

This command creates an RTL foreach statement. The foreach statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the foreach statement is created in the current instance.

Examples

The following example creates one foreach statement in the given instance with the literal statement named *RTL_LITERAL_2* and expression named *RTL_EXPRESSION_8*.

```
prompt> create_foreach_statement \\
   -statement [get_statements u1/u1/RTL_LITERAL_2 ] \\
```

Feedback

```
-expression [get_statements u1/u1/RTL_EXPRESSION_8] \\
-cell u1/u1 {"u1/u1/RTL_FOREACH_85"}
```

---

create_frame

Creates a frame view for the current block by extracting blockage, pin, and via information from the design view.

Syntax

status *create_frame*

```
[-block_all auto | true | false | used_layers | topBlockedLayerName |
 frontside_used_layers | frontside_all_layers | backside_userd_layers |
 backside_all_layers ]
[-block_core_margin layer_margin_list ]

[-source_drain_annotation file_name ]
```

Feedback

Data Types

topBlockedLayerName	string
layer_margin_list	list
port_layer_modes_list	list
layer_distance_list	list
layer_distance_mode_list	list
layer_name_list	list
cut_layer_name_list	list
via_list	list
port_list	list
layer_setting_list	list
connection_spare_layer_list	list
layer_width_list	list
port_contact_code_list	list
layer_mode_list	list
file_name	string

Arguments

`-block_all auto | true | false | used_layers | `*topBlockedLayerName*` | frontside_used_layers | frontside_all_layers | backside_userd_layers | backside_all_layers`

Controls whether the tool creates zero-spacing routing blockages in the frame view for the entire block, except for the area around the pins.

The valid values for this option are

- *false*

  The tool does not create zero-spacing routing blockages.

- *true*

  The tool creates a zero-spacing routing blockage on all layers.

- *used_layers*

  The tool creates a zero-spacing routing blockage only on layers used by the cell.

- *topBlockedLayerName*

  The tool creates a zero-spacing routing blockage only on the specified layer and the layers below it. The layer name must be a metal or poly layer defined in the technology file.

- *frontside_used_layers*

  The tool creates a zero-spacing routing blockage only on frontside layers used by the cell.

Feedback

- *frontside_all_layers*

  The tool creates a zero-spacing routing blockage on all frontside layers.

- *backside_used_layers*

  The tool creates a zero-spacing routing blockage only on backside layers used by the cell.

- *backside_all_layers*

  The tool creates a zero-spacing routing blockage on all backside layers.

- *auto* (the default)

  The tool determines whether to create zero-spacing routing blockages based on the design type of the cell. For analog, black-box, and module design types, the tool creates zero-spacing routing blockages on all layers (*true*). For macro cells, the tool creates zero-spacing routing blockages only on used layers (*used_layers*). For all other design types, the tool does not create zero-spacing routing blockages.

When the tool does not generate zero-spacing routing blockages in the frame view, it copies all of the physical geometries from the design view to the frame view.

When the tool generates zero-spacing routing blockages in the frame view, it preserves the detailed shapes within the DRC distance from the edges of the routing blockages. The tool generates the metal shapes to cover the area beyond the DRC distance. If a cut shape is covered by generated metal shapes on both the upper and lower metal layers, the tool does not include the cut shape in the frame view. Otherwise, the tool preserves the cut shape. For more information about the DRC distance, see the description of the *-drc_distances* option.

The setting specified by this option applies to all layers. However, if this option setting conflicts with the setting of the *-block_core_margin* option for a layer, the *-block_core_margin* option has priority for that layer.

`-block_core_margin` *`layer_margin_list`*

Creates zero-spacing routing blockages on the specified layers with the specified margin between the core blockage and the cell boundary.

Specify this argument using the following syntax:

```
{ { layer_name margin } ... }
```

The *layer_name* value can be the layer name defined in the technology file or the keyword "used_layers" or "all_layers".

Feedback

- For "used_layers", the margin value is for the non-empty metal or poly layers.
- For "all_layers", the margin value is for all metal and poly layers.

When there are combined settings, the priority from high to low is:

```
1) layer_name
2) used_layers
3) all_layers
```

The *margin* value can be zero, a positive number, or a negative number. When the specified margin is 0, the tool blocks the entire cell area, except for the area around the pins, with a zero-spacing routing blockage for the specified layer. A positive margin value specifies the distance between the generated zero-spacing routing blockage and the cell boundary. A negative margin value specifies the distance that the zero-spacing routing blockage extends outside the cell boundary.

The *margin* value can also be a keyword "auto_bloat", which means the tool automatically uses layer negative value of min_spacing of specified layer as the margin value. Therefore, the generated routing blockage is extended outside the cell boundary by min_spacing of the specified layer.

When generating zero-spacing routing blockages in the frame view, the tool preserves the detailed shapes within the DRC distance from the edges of the routing blockages. The tool generates the metal shapes to cover the area beyond the DRC distance. If a cut shape is covered by generated metal shapes on both the upper and lower metal layers, the tool does not include the cut shape in the frame view. Otherwise, the tool preserves the cut shape. For more information about the DRC distance, see the description of the *-drc_distances* option.

If this option setting conflicts with the setting of the *-block_all* option for a layer, this option setting has priority.

`-block_hole_and_diagonal_of_pin` *`layer_name_list`*

Specifies the layers to create zero-spacing routing blockages on holes and diagonal edges of the pin shapes.

It can prevent the unpreferred connection to the blocked area.

```
-block_lower_layers_of_pins none | via_blockage_upper |
via_blockage_lower | via_blockage_both | metal_blockage
```

Controls whether the tool creates zero-spacing routing blockages for ports which have multi-layer pin shapes. It will block lower layer pin shapes of the port, so only top layer pin shapes of the port can be connected.

Feedback

The option value controls where the zero-spacing routing blockages are added. It can prevent dropping via from upper/lower via layer or prevent same layer connecting.

- *none* (the default)

  Does not add blockages for lower layer pin shapes.

- *via_blockage_upper*

  Creates zero-spacing routing blockages on upper via layers for the lower layer pin shapes of the port. The blockage size is the same as the source pin shape.

- *via_blockage_lower*

  Creates zero-spacing routing blockages on lower via layers for the lower layer pin shapes of the port. The blockage size is the same as the source pin shape.

- *via_blockage_both*

  Creates zero-spacing routing blockages on both upper and lower via layers for the lower layer pin shapes of the port. The blockage size is the same as the source pin shape.

- *metal_blockage*

  Creates zero-spacing routing blockages on metal layers for the lower layer pin shapes of the port. The blockage size is the source pin shape size bloating minGrid.

For example:

Port A has pin shapes on M1, M2 and M3, so the lower layers are M1 and M2. According to the option value, the tool creates zero-spacing routing blockages on adjacent via layers or on same metal layers for M1 and M2 pin shapes.

Port B only has pin shapes on M2, so there is no lower layer pin shape to be blocked.

`-block_via_layers_by_pins` *`port_layer_modes_list`*

Controls whether the tool creates zero-spacing routing blockages for specific ports. This is a port-based and layer-based option.

Specify this argument using the following syntax:

```
{ { port_name {layer_name mode1 mode2} ... } ... }
```

Feedback

- *mode1* can be "none | upper | lower | both", the default is "none".

  Creates zero-spacing routing blockages on upper/lower via layers for certain layer pins.

- *mode2* (optional) can be "all | inside_only", the default is "all".

  Considers the cell boundary when adding blockages. If a pin shape is extended outside cell boundary, the tool only blocks the inside cell boundary area for the pin in "inside_only" mode.

`-drc_distances` *`layer_distance_list`*

Specifies the distance for each layer within which to preserve detailed shapes from the edges of a zero-spacing routing blockage generated by the *-block_all* or *-block_core_margin* option.

Specify this argument using the following syntax:

```
{ { layer_name distance } ... }
```

By default, the tool uses the maximum spacing value from the Layer section of the technology file for each layer.

`-color_based_dpt_flow false | true | auto`

Controls whether the tool creates the metal shapes beyond the DRC distance with attribute mask_constraint or not. The metal shapes are added by option block_all or block_core_margin in frame creation.

The valid values for this option are :

- *false*

  The metal shapes beyond the DRC distance are colorless and trimmed by colored shapes.

- *true*

  For metal layers, the metal shapes beyond the DRC distance are colored and trimmed by both colored and colorless shapes.

  For poly and below layers, the metal shapes beyond the DRC distance are still colorless and only trimmed by colored shapes.

- *auto* (the default)

  If the following color rules are defined in the technology file, the option is treated as *true*; otherwise, it is treated as *false*.

  ```
  sameColorSpanTblXMinSpacing
      sameColorSpanTblYMinSpacing
  ```

Feedback

```
        diffColorSpanTblXMinSpacing
        diffColorSpanTblYMinSpacing
```

`-connect_within_pin true | false | honor_port_attribute`

Controls whether the via enclosure must be within the pin shape.

This option affects via region creation. If *true*, the tool must place the via enclosure inside the pin shape when inserting vias in the via region. If *false*, the tool can place the via enclosure outside of the pin shape when inserting vias in the via region.

If *honor_port_attribute*, the tool honors "connect_within_pin" attribute of each port in via region creation. It performs "-connect_within_pin false" for ports with "connect_within_pin" attribute "none" and performs "-connect_within_pin true" for the other ports, which attribute may be "via" or "via_wire".

The default is *true*.

`-convert_metal_blockage_to_zero_spacing` *`layer_distance_mode_list`*

Converts regular routing blockages on the specified layers in the design view to zero-spacing routing blockages in the frame view, and specifies the distance by which to enlarge the blockage when doing the conversion. Different enlarge distance can be specified for blockages touching pins and not touching pins by setting the mode as 'touch_pin' and 'no_touch_pin' accordingly. Mode 'all' implies the enlarge distance will be applied to all regular routing blockages on the specified layer.

Specify this argument using the following syntax:

`{ { layer_name distance mode} ... }`

The layer name must be a metal or poly layer defined in the technology file. The distance value must be no less than zero. The mode string must be one of 'touch_pin', 'no_touch_pin', or 'all'.

`-create_zero_spacing_blockages_around_pins` *`layer_width_list`*

Specifies the width to create zero-spacing routing blockages around pins by layer.

For the pin on cell boundary, the routing blockage will not be generated on the boundary side.

For the shallow pin, the routing blockage will not be generated on the channel area, which is from *pin* to *cell boundary*.

For the deep pin, all sides of the pin will have routing blockages.

Feedback

Specify this argument using the following syntax:

```
{ { layer_name width } ... }
```

The width should be no less than zero.

`-design_rule_via_blockage_layers` *cut_layer_name_list*

Converts zero-spacing routing blockages on the specified cut layers of the frame view to design rule via routing blockages. The option accepts a list of cut layers defined in the technology file and works only for zero-spacing routing blockages on the specified layers.

A design rule via routing blockage is a routing blockage whose *is_design_rule_blockage* attribute is *true*. The purpose of a design rule via routing blockage is to honor the spacing between a via blockage layer and a via layer in the DesignRule section of the technology file. For example,

```
DesignRule {
    layer1 = 'via1Blockage'
    layer2 = 'V1'
    minSpacing = 0.084
}
```

`-derive_pattern_must_join true | exclude_pg | false`

Sets *pattern_must_join* attribute as *true* to the port which has multiple terminals on one metal layer. Only terminals on metal layers are considered, terminals on cut layers are ignored. The option value controls which type of port should be checked by this option.

The valid values for this option are

- *true*

  The tool derives *pattern_must_join* attribute for the following ports:

1. The *port_type* attribute is not power/ground related.
2. The *port_type* attribute is power/ground related, and the *is_secondary_pg* attribute is *true*.
3. The *port_type* attribute is power/ground related, and the port name is specified in the *-include_routing_pg_ports* option.

- *exclude_pg*

  The tool derives *pattern_must_join* attribute only for the ports which are not power/ground related.

Feedback

- *false* (the default)

  The tool does not set *pattern_must_join* attribute as *true* to any port.

`-enable_via_regions_for_all_design_types true | false`

Controls whether to create via regions for all design types.

The default is *false*. Only create via regions for standard cell group design types.

When this option is set to *true*, the tool also checks whether the -block_all or -block_core_margin is set to *true*. And then the tool checks the direction of pin shape direction, and cut channel to the closest boundary on same layer or upper layer base on the direction of pin shape.

- For "vertical" pin:

  If the pin is near to "bottom or top" boundary, create channel on "same" metal layer.

  If the pin is near to "left or right" boundary, create channel on "upper" metal layer.

- For "horizontal" pin:

  If the pin is near to "left or right" boundary, create channel on "same" metal layer.

  If the pin is near to "bottom or top" boundary, create channel on "upper" metal layer.

- For "square" pin:

  Create channel to the nearest boundary on "same" metal layer.

`-hierarchical true | false`

Controls whether to extract geometries in subblocks.

If *true*, the tool performs hierarchical extraction. If *false*, the tool ignores the geometries in subblocks.

The default is *true*.

`-include_nondefault_via` *`via_list`*

Specifies the nondefault vias to consider when calculating the via regions. Specify the nondefault vias by using the contact code names defined in the technology file.

The *via_list* can accept keyword "auto", which means when there is no via region created by default vias, the tool automatically includes the nondefault vias to calculate the via regions.

Feedback

By default, the extraction process considers only the default vias.

`-include_routing_pg_ports` *port_list*

Specifies the power and ground port names that require via regions and access edges in the frame view. Usually, these ports are the secondary or bias power and ground ports, which are routed by the signal router.

By default, power and ground ports are ignored when generating via regions and access edges.

`-keepout_spacing_for_non_pin_shapes` *layer_setting_list*

Creates zero-spacing routing blockages around non-pin shapes on the specified layers with the specified *extension_spacing* from the shape boundary and with the specified *corner_keepout_spacing* from the shape corners.

An *edge_threshold* value is also specified for the layer so that frame can identify "edges" of non-pin shapes. If the created zero-spacing routing blockages are overlap with pins, the overlap region on the non-edge sides are trimmed by pins.

Specify this argument using the following syntax:

```
{ { layer_name
 {edge_threshold extension_spacing corner_keepout_spacing} } .
.. }
```

The *edge_threshold* is for determining edges of shapes. If a segment along the contour of the connected non-pin shape has length smaller than or equal to the threshold, the segment is an edge. But if the segment belongs to concave part of the contour, it is still not an edge. The value should be zero or a positive number. If the value is zero, routing blockages are trimmed by pins on each side of the shape.

The *extension_spacing* is for creating zero-spacing routing blockages around non-pin shapes in direction top, bottom, left and right. The value should be zero or a positive number. If the value is zero, no routing blockage is created.

The *corner_keepout_spacing* is for creating zero-spacing routing blockages around corners of non-pin shapes. The value should be zero or a positive number, and it should be smaller than or equal to the *extension_spacing*. If the value is zero, no corner routing blockage is created.

If *-block_all* is *true* or *-block_core_margin* is specified for the same layer, this option becomes invalid.

`-merge_metal_blockage true | false`

Controls whether to merge metal shapes and regular routing blockages to reduce the number of shapes.

Feedback

If *true*, the extraction process fills in the space between the two shapes when two nearby geometries are within the spacing threshold, creating a single larger shape for the blockages in the frame view. The spacing threshold is equal to minimum spacing times two plus minimum width.

The default is *false*.

`-pin_channel_distances` *`layer_distance_list`*

Specifies the pin channel cutting distance from the block boundary to core area per layer. If the distance of the pin from the block boundary is smaller than the pin channel cutting distance, the tool will cut channel from the pin through shapes or blockages to boundary.

By default, the tool uses layer minWidth + minSpacing from the technology file as the pin channel cutting distance.

`-pin_must_connect_area_layers` *`connection_spare_layer_list`*

Specifies connection layer and associated spare layer pairs to designate the required via connection area within the pin geometry.

Specify this argument using the following syntax:

```
{ { connection_layer_name spare_layer_name } ... }
```

The spare layer can be any layer except a layer with a standard mask name.

By default, the router can connect to any part of a large pin. To restrict the connection to a subarea of a large pin, specify the subarea polygon on a spare layer and specify the spare layer associated with each connection layer using this option.

The following example associates connection layer M1 with spare layer S1 and connection layer M2 and spare layer S2:

```
{ {M1 S1} {M2 S2} ... }
```

`-pin_must_connect_area_thresholds` *`layer_width_list`*

Specifies connection layer and the width threshold pairs for automatic determination of the required via connection area within the pin geometry.

Specify this argument using the following syntax:

```
{ { layer_name width } ... }
```

Specify the width threshold using the unit size defined in the technology file.

By default, the router can connect to any part of a large pin. To automatically restrict the connection to a subarea of a pin with various geometry widths, use this option to specify the width threshold for each layer.

Feedback

For example,

```
{ {M1 0.56} {M2 0.63} ... }
```

The tool does not allow via connections in areas within a pin that have a width smaller than the specified threshold width for the layer.

`-port_contact_selections` *`port_contact_code_list`*

Specifies the contact codes to use for specific ports during via region generation.

Specify this argument using the following syntax:

```
{ { port_name { contact_code_list } } ... }
```

Specify the contact codes by using the names defined in the technology file.

Via regions for the specified ports use only the specified contact codes. Via regions for all other ports use only the default contact codes. The via regions generated by this option are hard constraints for the signal router.

`-preserve_metal_blockage true | false | auto`

Controls whether to preserve all metal shapes and routing blockages around pins as they exist in the design view.

If *true*, all metal shapes and routing blockages around pins are retained exactly. If *false*, the metal shapes and routing blockages are trimmed by pins only when the metal shapes and routing blockages touch a pin. The trimming distance is the maximum spacing value from the technology file. The trimmed metal shapes and routing blockages are converted to zero-spacing routing blockages.

The default value is *auto*. The tool determines whether to preserve the metal shapes and blockages based on the design type of the cell. For library cells, diode cells, end cap cells, fill cells, filler cells, feedthrough cells, and well-tap cells, the tool preserves the metal shapes (*true*). For all other design types, the metal shapes and blockages are trimmed (*false*).

If this option setting conflicts with the setting of the *-trim_metal_blockage_around_pin* option for a layer, the *-trim_metal_blockage_around_pin* option has priority for that layer.

`-trim_metal_blockage_around_pin` *`layer_mode_list`*

Specifies how to trim metal shapes and routing blockages around pins by layer. To prevent unpredictable spacing violations during routing, make sure that you set the proper value for this option.

Specify this argument using the following syntax:

```
{ { layer_name touch|all|none } ... }
```

Feedback

If set to *touch*, only the metal shapes and routing blockages that touch a pin are trimmed. If set to *all*, all metal shapes and routing blockages around pins are trimmed. If set to *none*, no metal shapes and routing blockages are trimmed. The trimming distance is the maximum spacing value from the technology file. The trimmed metal shapes and routing blockages are converted to zero-spacing routing blockages.

The default is null, and the behavior is controlled by the setting of the *-preserve_metal_blockage* option.

When this option is specified for a layer, its setting has priority over the *-preserve_metal_blockage* setting for that layer.

`-read_fill_cells true | false`

Controls whether to extract geometries in fill cells.

If *true*, the tool performs extraction for fill cells. If *false*, the tool ignores the geometries in fill cells.

The default is *false*.

`-remove_non_pin_shapes` *`layer_mode_list`*

Specifies the mode to remove the non-pin shapes by layer.

Specify this argument using the following syntax:

`{ { layer_name none|all|core } ... }`

- *none*

  The non-pin shapes of the given layer are not removed and which is the default behavior.

- *all*

  All non-pin shapes of the given layer are removed.

- *core*

  The non-pin shapes inside the core area of the given layer are removed. The core area is within the DRC distance from the edge of the block boundary.

This option is recommended to use with the *-block_all* or *-block_core_margin* option. The combination can create proper blocked area from the boundary and make sure that there is no missing DRC for the routing wire due to the non-pin shapes are removed.

Feedback

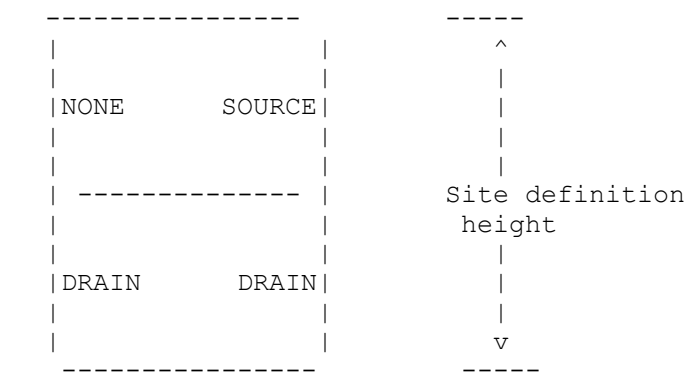
`-source_drain_annotation` *file_name*

Specifies the name of the input file that contains source-drain annotation information for the cell. The file identifies the type of transistor geometry (SOURCE, DRAIN, or NONE) that abuts each side (left or right) and subrow (upper or lower half of the tile height) of the cell. The tool reads this source-drain information from the file and annotates the information in the frame view. Each side of each subrow of the cell receives one annotation: SOURCE, DRAIN, or NONE; the default annotation is DRAIN. Extraction of this property requires the site definition information.

The following is an example source-drain annotation file:

```
CELL cell_name
    LEFT
        DRAIN ROW1_1
        NONE ROW1_2
    END LEFT
    RIGHT
        DRAIN ROW1_1
        SOURCE ROW1_2
    END RIGHT
END CELL
```

This example annotates a single-height standard cell as follows:



The ROW*x_y* notation means row number *x* and subrow number *y*, counting from bottom to top, starting with 1 and up to the number of rows:

```
ROW1_1 = row 1, lower half of row 1
ROW1_2 = row 1, upper half of row 1
ROW2_1 = row 2 (upper row of double-height cell), lower half of
 row 2
ROW2_2 = row 2 (upper row of double-height cell), upper half of
 row 2
```

Feedback

Description

This command creates a frame view for the current block by extracting blockage, pin, and via information from the design view. The frame view of a block contains all the information needed for placement and routing. The exclusion of unnecessary data reduces the database size and routing time.

As part of the frame extraction process, the tool determines the region within each pin where the center of a via can connect. This region, called the via region for the pin, is part of the generated frame view. This information gives the router guidance about where it can make connections to a pin. As a result, the router can quickly find the via connection position. Calculating the via region during extraction saves significant runtime for router.

Obstructions in a frame view include three kinds of geometries: shape, regular routing blockage, and zero-spacing routing blockage. A shape is a non-pin geometry on the metal, cut, and device layers defined in the Layer sections of the technology file. A regular routing blockage is a routing blockage with an *is_zero_spacing* attribute of *false*. A zero-spacing routing blockage is a routing blockage with an *is_zero_spacing* attribute of *true*. The router checks all design rules defined in the technology file between the net shapes and the shapes in the frame view. The router treats a regular routing blockage as a shape to keep a safe distance from the surrounding objects. For a zero-spacing routing blockage, the router checks only that there is no overlap (zero spacing) between the blockage and the net shapes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example extracts the blockage, pin, and via information from the current block.

```
prompt> create_frame
```

The following example uses nondefault via definitions in addition to the default via definitions during via region extraction.

```
prompt> create_frame -include_nondefault_via {VIA23 VIA23A}
```

The following example generates a via region for contact codes VIA12HH and VIA12HV for port A and a via region for contact code VIA12 for port B.

```
prompt> create_frame \\
   -port_contact_selections { {A {VIA12HH VIA12HV}} {B {VIA12}} }
```

The following example blocks M1 and M2 pin shapes of port A, and M2 and M3 pin shapes of port B.

Feedback

```
prompt> create_frame \\
        -block_via_layers_by_pins { {A {M1 both} {M2 lower}} {B {M2 both}
 {M3 lower inside_only}} }
```

- create_abstract

---

create_freeze_silicon_leq_change_list

Creates logic equivalence (LEQ) change list for engineering change order (ECO) cells. This command is typically used in the freeze silicon ECO flow.

Syntax

status *create_freeze_silicon_leq_change_list*

```
[-cells cell_objects]
-output output_file_name
```

Data Types

cell_objects	collection
output_file_name	string

Arguments

`-cells cell_objects`

Specifies the ECO cells for which to create LEQ change list. The given cells must meet three requirements:

- Be leaf cell.
- Have the is_fs_eco_add attribute as true.
- Have the eco_change_status attribute as one of create_cell, add_buffer, add_buffer_on_route, change_link and size_cell.

If this option isn't specified, this command will create LEQ change list for all mappable ECO cells in current design. These ECO cells meet the above mentioned requirements.

`-output output_file_name`

Specifies name of the file to write LEQ change list. If this file doesn't exist, the command will create one. If this file already exists, its contents are discarded and the file is treated as a new empty file.

Feedback

Description

The *create_freeze_silicon_leq_change_list* command automatically searches for LEQ replacement for ECO cells. It skips same reference lib mapping. For each ECO cells, the command outputs a bunch of TCL commands to the specified file. These TCL commands either rebind ECO cell to a reference library that has instantiated spare cell, or replace ECO cell with its LEQ replacement.

The command first searches for a logic equivalence replacement for each ECO cell one by one. Spare cells in current design meets following requirements can be used to create LEQ change list:

- Its is_eco_fs_dont_use attribute hasn't been defined, or value of is_eco_fs_dont_use is false.
- Its fs_mapped_cell_name attribute hasn't been defined, or value of fs_mapped_cell_name hasn't been set.

Currently this command supports maximum of 2 gate level logic equivalence. This means if the LEQ replacement for a cell has its gate level greater than 2, the command won't create LEQ change list for the cell.

Logic equivalence has two types:

- Same function Id mapping

  If there is a spare cell having same function Id as the ECO cell, this command will reserve the spare cell for same function Id mapping.

- LEQ mapping

  If same function Id mapping fails, this command will try LEQ replacement rules on the cell, until find a LEQ replacement that can be composed of existing spare cells.

Then the command dumps LEQ change list to the output file:

- Same function Id mapping

  This command dumps *size_cell* command to the output file to rebind ECO cell to the reference library of the spare cell that has same function id as the ECO cell.

- LEQ mapping

  This command dumps *remove_cell* command to the output file first to remove ECO cell, then dump a series of *create_cell*, *create_net*, *connect_net* commands to create LEQ.

After running this command, User can check the commands in the output file and then source the file.

Feedback

Examples

Suppose there is a ECO cell. Its reference library is AND2X1. Its function is AND. There is a spare cell in current design. Its reference library is AND2XL. AND2XL has same function id as AND2X1. The command will rebind the ECO cell to AND2XL.

```
prompt > create_freeze_silicon_leq_change_list -output leq.tcl
```

leq.tcl will have following content:

```
size_cell ECO_0 AND2XL -not_spare_cell_aware
```

If there is no same function Id spare cell, but there are two spare cells NAND and INV, then leq.tcl will look like:

```
remove_cell ECO_0
create_module AND2X1_leq_1
create_cell ECO_0 AND2X1_leq_1
current_instance ECO_0
create_port -direction in A
create_net A
connect_net A A
create_port -direction in B
create_net B
connect_net B B
create_port -direction out Y
create_net Y
connect_net Y Y
create_cell leq_cell_0 INVX2
create_net leq_net_1
connect_net leq_net_1 leq_cell_0/A
connect_net Y leq_cell_0/Y
create_cell leq_cell_1 NAND2X1
connect_net A leq_cell_1/A
connect_net B leq_cell_1/B
connect_net leq_net_1 leq_cell_1/Y
```

---

create_frontend_tcd_cells

Inserts front-end testkey critical dimension cells (TCDs) into the design.

Syntax

status *create_frontend_tcd_cells*

Feedback

```
-lib_cells libcells
-window_size {width height}
[-tcd_spacing distance ]
[-other_cell_spacing distance]
[-icovl_spacing distance]
[-respect_blockage none | hard_only | both]
[-density fvalue]
[-orientation orient]
[-check_only]
[-include_small_windows]
[-bbox {{x1 y1} {x2 y2}} ]
[-snap_to_fin_grid]
[-place_at_window_center]
[-min_tcd_count count]
[-max_tcd_spacing spacing]
```

Data Types

libcells	list of lib cells
width	float
height	float
distance	float
fvalue	float
orient	orientation
x1	float
y1	float
x2	float
y2	float
count	int
spacing	float

Arguments

`-lib_cells` *libcells*

Specifies the front-end TCD library cells.

`-window_size` *{width height}*

Specifies the width and height of insertion window size.

`-tcd_spacing` *distance*

Specifies the minimum distance between two front-end TCD cells.

`-other_cell_spacing` *distance*

Specifies the minimum distance between front-end TCD cells and cells other than front-end TCDs and ICOVL cells.

`-icovl_spacing` *distance*

Specifies the spacing between front-end TCDs cells and ICOVL cells.

Feedback

`-respect_blockage none | hard_only | both`

Specifies whether the front-end TCD cell should respect blockages. Possible values are *none*, *hard_only*, and *both* defined as follows:

- none: Ignore all blockages (Default).
- hard_only: Respect hard blockages only.
- both: Respect both hard and soft blockages.

`-density` *`fvalue`*

Specifies the target percentage of windows that contains a front-end TCD cell.

`-orientation` *`orient`*

Specifies the front-end TCD cell orientation. Valid values are R0, R90, R180, R270, MX, MXR90, MY, MYR90.

`-check_only`

Checks the current design for front-end TCD violations based on rules specified in other options. An error message is issued for each violation.

`-include_small_windows`

Includes small windows at the last row/column for TCD insertion. By default, these small windows are excluded.

`-bbox` *`{{x1 y1} {x2 y2}}`*

Specifies an insertion area. This area will be divided into the specified window size for TCD insertion. By default, the die area is the insertion area.

`-snap_to_fin_grid`

Places the lower-left corner of the TCD cell to align with the FinFET grid. By default, alignment is not required.

`-place_at_window_center`

Changes the placement preference for TCD cells to be close to window center when specified to:

1. Place TCD in center of window 2. Place TCD in the channel between blocks or IPs (if blocks are not abut) 3. Place TCD at blocks or IP corner

By default, TCD cells are not placed at the center of window.

`-min_tcd_count` *`count`*

Specifies the minimum number of TCD that must be inserted by this command.

Feedback

`-max_tcd_spacing` *spacing*

Specifies the maximum spacing between frontend TCD cells.

Description

This command inserts front-end testkey critical dimension cells (front-end TCDs), which are used to increase design for manufacturability (DFM) and yield.

Front-end TCDs are inserted during floorplanning stage, after macro placement and before tap cells, power switch cells, pre-inserted cells, and so on. Front-end TCDs have no metal layers and no power ports, therefore allowing routing over them.

TCD width and height are not even multiples of unit tile width and height. They are placed similar to regular macros.

A front-end TCD cell is a type of cover cell that allows overlap with other cells.

Front-end TCD cell insertion should prevent die cell area penalty by honoring the following insertion priority:

- Place at window center if -place_at_window_center option is specified
- Place TCD in the channel between blocks or IPs (if blocks are not abut)
- Place TCD in blocks or IP corner
- Place TCD in die area

Examples

The following example inserts the front-end TCD cell DM1 into windows of width 1000 microns and height 1200 microns. Spacing between DM1 cells is 10 microns. Spacing between DM1 cells and other cells is 2 microns.

```
prompt> create_frontend_tcd_cells -lib_cells {DM1} \\
   -window_size {1000 1200} -tcd_spacing 10 -other_cell_spacing 2
```

---

create_frontside_fibs

Insert frontside FIB structures in the design with specified grid pattern. Each FIB structure contains four logic cells and four to eight tie low cells. Each logic cell has one to two inputs. Each logic cell input is connected to one tie low cell. The nets between FIB logic cells and tie low cells are routed on the top two layers specified.

Feedback

Syntax

status *create_frontside_fibs*

```
-lib_cells lib_cell_list
-tie_low_cell tie_low_lib_cell
[-pitch {x_pitch y_pitch}]
[-offset {x_offset y_offset}]
[-max_route_layer layer_name]
[-bbox bounding_box]
```

Data Types

```
lib_cell_list     collection
tie_low_lib_cell  string
x_pitch           float
y_pitch           float
x_offset          float
y_offset          float
offset_list       list
layer_name        string
bounding_box      rectangle
```

Arguments

`-lib_cells lib_cell_list`

Specifies a collection of four logic cells.

`-tie_low_cell tie_low_lib_cell`

Specifies lib cell for tie low cell.

`-pitch {x_pitch y_pitch}`

FIB structures are inserted in the design in grid pattern. They are spaced by x_pitch horizontally and by y_pitch vertically.

`-offset {x_offset y_offset}`

The first (lower left) FIB structure is inserted at {*x_offset y_offset*}.

`-max_route_layer layer_name`

Specifies the maximum routing layer. The nets between FIB cells are routed on the *max_route_layer* and the layer below it. When not specified, the default is the top routing layer in the tech file.

`-bbox bounding_box`

Specifies the area for FIB insertion. When not specified, FIBs are inserted in the core area.

Feedback

Description

This command creates connection from the signal net to the port. A signal elevation buffer is inserted.

This command also promote existing signal elevator pins on macros to the port.

When *-create_terminals* option is used, the command search for existing signal elevator ports and create terminals.

Examples

```
prompt> create_frontside_fibs -lib_cells {NOR2BX1 AND2XL BUFX8 INVX6}
 -tie_low_cells TIELO

prompt> create_frontside_fibs -lib_cells {NOR2BX1 AND2XL BUFX8 INVX6}
 -tie_low_cells TIELO \\
         -pitch {40 40} -offset {10 10} -max_route_layer METAL4

prompt> create_frontside_fibs -lib_cells {NOR2BX1 AND2XL BUFX8 INVX6}
 -tie_low_cells TIELO \\
         -pitch {40 40} -offset {10 10} -max_route_layer METAL4 -bbox
 {{200 200} {300 300}}
```

---

create_function

Creates one RTL statement of type function.

Syntax

collection *create_function*

```
-return_type type
[-name name]
[-scope scope]
[-input input]
]-module module]
```

Data Types

```
type                string
name                string
scope               collection
input              collection
module              collection
```

Arguments

`-return_type type`

Specifies the return type of the function. The available values are "reg" or "integer".

Feedback

`-name` *name*

Specifies the name to be used for the function statement.

`-scope` *scope*

Specifies the scope to create the function statement in. If this option is not specified, the function is created in the current module.

`-input` *input*

Specifies the inputs to be accepted by the function. It can be more than one. RTL variable is accepted as input.

`-module` *module*

Specifies the module to create the function statement in.

Description

This command creates a RTL statement of type function. The function is created in the specified scope. The function is created in the current design if no module is specified.

Examples

The following example creates one function statement in the current module with the function named "func1", return_type "reg", and two variables inputs.

```
prompt > create_function -name func1 -return_type reg -inputs {rtlVar_c
 rtlVar_i}
{"func1"}
```

The following example creates one function statement in the given scope and return type "integer".

```
prompt > create_function -scope alw9_V -return_type integer
{"u1/u1/RTL_FUNCTION_85"}
```

- remove_statements

---

create_gap_lib_cells

Creates lib_cells from one of more of the library gaps discovered by a find_library_gaps run.

Syntax

status *create_gap_lib_cells*

Feedback

```
-analysis         analysis_name
-libset           libset_name
-gap_names        gap_names_string_list
[-name_prefix     string]
[-base_name       lib_cell_name_string]
[-name_suffix     string]
[-lib_cell_names lib_cell_names_string_list]
```

Data Types

```
analysis     string
libset      string
gap_names     list-of-strings
name_prefix     string
base_name     string
name_suffix     string
lib_cell_names    list-of-list-of-strings
```

Arguments

`-analysis`

Name of the analysis in use.

`-libset`

The libset which has a valid suggestion library for creating new gap library cells

`-gap_names`

The name of the gaps being considered. Use *"-gap_names {all}"* for considering all the gaps.

`-name_prefix`

The name prefix for the new gap lib cell being created. Default prefix is "libra". The name of new gap lib cell is constructed by name_prefix + base_name + drive_strength + name_suffix.

`-base_name`

The base name for the new gap lib cell being created. For example if you are creating a new gap cell between AND2_D2 and AND_D5, you might choose 'AND2' as the base name for the new gap lib cell(s). By default, the tool will assign the base name from the lower library cell. The name of new gap lib cell name is constructed by name_prefix + base_name + drive_strength + name_suffix.

`-name_suffix`

The name suffix for the new gap lib cell being created. Default suffix is an empty string. The name of new gap lib cell is constructed by name_prefix + base_name + drive_strength + name_suffix.

Feedback

`-lib_cell_names`

Overrides the auto-generated names of the new gap lib cell(s). You can use it to directly give the name to new gap lib cell(s). The number of the lib cell names must match with the number of the gaps. For example, you can have g0 with gap size of 2 and g1 with gap size of 1. In this case, the options must be used as *"-gap_names {g0 g1} -lib_cell_names { {name1 name2} {name3} }"*. The first new gap lib cell in g0 will be named as "name1", and the second new gap lib cell in g0 will be named as "name2". The new gap lib cell in g1 will be named as "name3". This option cannot be used with *"-gap_names {all}"*.

Description

The create_gap_lib_cells command creates new library cells from the gaps provided by -gap_names option in the command line. It will only create the gaps that belong to provided analysis name. The library cells created have drive strength and other physical properties that are intermediate between the lower and upper library cells in the gap. The newly created library cells are placed in the suggestion library of the provided library set. The gap information is then updated to reflect that library cells were already created for this gap. A summary count of gap library cells created is reported at the end of command execution.

EXAMPLES:

```
create_gap_lib_cells -analysis <analysisName> -libset <libsetName>
 -gap_names {all}
report_library_analysis -analysis_name <analysisName> -analysis_type gap
```

See Also

- report_library_analysis

---

create_generated_clock

Creates a generated clock object.

Syntax

```
collection create_generated_clock
[-name clock_name]
-source master_pin
[-divide_by divide_factor | -multiply_by multiply_factor |
 -edges edge_list ]
[-combinational]
[-duty_cycle percent]
[-invert]
[-preinvert]
[-edge_shift edge_shift_list]
[-add]
```

Feedback

```
[-master_clock clock]
source_objects
[-comment comment]
```

Data Types

```
clock_name          string
master_pin          list
divide_factor       int
multiply_factor     int
edge_list           list
percent             float
edge_shift_list     list
clock               string
source_objects      list
comment             string
```

Arguments

`-name clock_name`

Specifies the name of the generated clock. If you omit this option, the clock receives the same name as the first clock source specified in the *-source* option. If you specify the *-add* option, you must use the *-name* option and the clocks with the same source must have different names.

`-source master_pin`

Specifies the master clock source (a clock source pin in the design) from which to derive the clock waveform. Note that the actual delays (latency) for the generated clock are computed using its own source pins and not the *master_pin*.

`-divide_by divide_factor`

Specifies the frequency division factor. If the *divide_factor* value is *2*, the generated clock period is twice as long as the master clock period.

`-multiply_by multiply_factor`

Specifies the frequency multiplication factor. If the *multiply_factor* value is *3*, the generated clock period is one-third as long as the master clock period.

`-edges edge_list`

Specifies a list of integers that represents edges from the source clock that are to form the edges of the generated clock. The edges are interpreted as alternating rising and falling edges and each edge must be not less than its previous edge. The number of edges must be an odd number and not less than 3 to make one full clock cycle of the generated clock waveform. For example, *1* represents the first source edge, *2* represents the second source edge, and so on.

Feedback

`-combinational`

The source latency paths for this type of generated clock only includes the logic where the master clock propagates. The source latency paths will not flow through sequential element clock pins, transparent latch data pins or the source pins of other generated clocks.

`-duty_cycle` *`percent`*

Specifies the duty cycle, as percentage, if frequency multiplication is used. Duty cycle is the high pulse width.

`-invert`

Inverts the generated clock signal in the case of frequency multiplication and division. This option first creates the gen- erated clock and then inverts the generated clock signal.

`-preinvert`

Creates a generated clock based on the inverted clock signal. This option first inverts the signal and then creates the gener- ated clock signal.

`-edge_shift` *`edge_shift_list`*

Specifies a list of floating point numbers that represents the amount of shift, in library time units, that the specified edges are to undergo to yield the final generated clock waveform. The number of edge shifts specified must be equal to the number of edges specified. The values can be positive or negative. positive indicates a shift later in time, negative a shift earlier. For example, *1* indicates that the corresponding edge is to be shifted by one library time unit.

`-add`

Specifies whether to add this clock to the existing clock or to overwrite. Use this option to capture the case where multiple generated clocks must be specified on the same source, because multiple clocks fan into the master pin. Ideally, one generated clock must be specified for each clock that fans into the master pin. If you specify this option, you must also use the *-name* and *-master_clock* options.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the tool must explore all possible combinations of launch and capture clocks. Use the *set_false_path* command to disable unwanted clock combinations.

`-master_clock` *`clock`*

Specifies the master clock to be used for this generated clock if multiple clocks fan into the master pin. If you specify this option, you must also use the *-add* option.

Feedback

source_objects

Specifies a list of ports, pins or nets defined as generated clock source objects. When a net is used as the source, the first driver pin of the net is the actual source used in creating the generated clock.

-comment *comment*

Associates a string description with the command for tracking purposes. This can be useful when writing out SDC to a tag, such as the methodology or tool that originally synthesized the command.

Description

Creates a generated clock object. Creates a generated clock in the current design. If successful, the command returns a collection containing the new or modified generated clock.

You can specify a pin or a port as a generated clock object. The command also specifies the clock source from which it is generated. The advantage of using this command is that whenever the master clock changes, the generated clock automatically changes.

The generated clock can be created as a frequency divided clock (by using the *-divide_by* option), frequency multiplied clock (by using the *-multiply_by* option), special divide by one (by using the *-combinational* option), or an edge-derived clock (by using the *-edges* option). The frequency-divided or frequency-multiplied clock can be inverted by using the *-invert* option. The shifting of edges of the edge-derived clock is specified by using the *-edge_shift* option. The *-edge_shift* option is used for intentional edge shifts and not for clock latency.

The number of edges specified by *-edges* to make one period of the generated clock waveform must be an odd number equal to or greater than 3. For example, in the following command:

```
create_generated_clock -source clk -edges { 1 3 5 } [get_pins flop/Q]
```

edge 1 indicates the first rising edge of the generated clock, edge 3 indicates the first falling edge of the generated clock, and edge 5 indicates the next rising of the generated clock. Note that the period of the generated clock is determined by the final entry in the edge list.

Non-increasing edges, such as *-edges { 1 1 3 }*, are allowed and usually used with *-edge_shift* to produce a generated clock pulse independent of the duty cycle of the master clock itself.

If a generated clock is specified with a *divide_factor* value that is a power of 2 (1, 2, 4, ...), the rising edges of the master clock are used to determine the edges of the generated clock. If the *divide_factor* value is not a power of two, the edges are scaled from the master clock edges.

Feedback

Using the *create_generated_clock* command on an existing *generated_clock* object overwrites its attributes. The *generated_clock* objects are expanded to real clocks at the time of analysis.

The following commands can reference the generated_clock: *set_clock_latency*, *set_clock_uncertainty*, *set_propagated_clock*, and *set_clock_transition*.

For internally generated clocks, the tool automatically computes the clock source latency if the master clock of the generated clock has propagated latency and no user-specified value for generated clock source latency exists.

If the master clock is ideal and has source latency, and there is no user-specified value for the generated clock's source latency, then zero source latency is assumed.

To display information about generated clocks, use the *report_clocks* command.

Multicorner-Multimode Support

This command works only on the current mode.

Examples

The following example creates a frequency divide_by 2 generated clock.

```
prompt> create_generated_clock -divide_by 2 \\
   -source [get_pins CLK] [get_pins u0]
```

The following example creates a frequency divide_by *3* generated_clock. If the master clock period is *30*, and master waveform is *{24 36}*, the generated clock period is *90* with waveform *{72 108}*.

```
prompt> create_generated_clock -divide_by 3 \\
   -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a frequency multiply_by *2* generated_clock with a duty cycle of *60*%.

```
prompt> create_generated_clock -multiply_by 2 -duty_cycle 60 \\
   -source [get_pins CLK] [get_pins u1]
```

The following example creates a frequency multiply_by *3* generated_clock with a duty cycle equal to the master clock duty cycle. If the master clock period is *30*, and master waveform is *{24 36}*, the generated clock period will be *10* with waveform *{8 12}*.

```
prompt> create_generated_clock -multiply_by 3 \\
   -source [get_pins CLK] [get_pins div3/Q]
```

The following example creates a generated clock whose edges are edges *1*, *3*, and *5* of the master clock source.

Feedback

```
prompt> create_generated_clock -edges {1 3 5} \\
   -source [get_pins CLK] [get_pins u2]
```

The following example shows the generated clock in the previous example with each derived edge shifted by *1* time unit.

```
prompt> create_generated_clock -edges {1 3 5} -edge_shift {1 1 1} \\
   -source [get_pins CLK] [get_pins u3]
```

The following example creates an inverted clock.

```
prompt> create_generated_clock -divide_by 1 -invert
```

The following example creates a rising edge pulse triggered by the rising edge of its master clock.

```
prompt> create_generated_clock -edges {1 1 3} -edge_shift {0 5 0} \\
   -source [get_pins CLK] [get_pins u4]
```

The following example creates a falling edge pulse triggered by the rising edge of its master clock with a period 10.

```
prompt> create_generated_clock -edges {1 1 3} -edge_shift {0 5 0} \\
   -invert -source [get_pins CLK] [get_pins u5]
```

The following example creates a frequency doubling pulse. A rising edge pulse triggered by both rising and falling edges of its master clock with a period of 10.

```
prompt> create_generated_clock -edges {1 1 2 2 3} -edge_shift {0 2.5 0
 2.5 0} \\
   -source [get_pins CLK] [get_pins u6]
```

Feedback

create_geo_mask

Creates a geo_mask object.

Syntax

collection *create_geo_mask*

```
[-objects object_list]
[pos_object_list]
[-merge]
```

Data Types

```
object_list       collection
pos_object_list   collection
```

Arguments

`-objects object_list`

Specifies the objects to be used to define the geometric region to be covered by the geo_mask. Objects may be a heterogenous collection of poly_rects, geo_masks, shapes, layers, and other physical objects.

In the case of poly_rects, geo_masks, shapes, or other physical objects, the resulting area will include the areas of each object. In the case of layers, the resulting area will include the area of every shape in the layer.

pos_object_list

Specifies the objects to be used to define the geometric region to be covered by the geo_mask. This positional option is provided for compatibility with other tools.

`-merge`

Indicates whether the resulting geo_mask should be merged. By default, the resulting geo_mask may contain distinct overlapping or adjacent regions. When this flag is set, the area in the geo_mask is simplified by removing overlapping area and merging adjacent regions.

Description

This command creates a new geo_mask object and returns a collection that contains the new object. geo_masks represent polygonal regions of arbitrary angularity, and can be used for geometrical computation. The region represented by a geo_mask may not necessarily be contiguous, and may also be empty. Calling this command with no arguments will return a geo_mask representing an empty region with zero area.

Feedback

Examples

The following example creates a geo_mask with a rectangular region.

```
prompt> create_geo_mask -objects [create_poly_rect -boundary {{0 0} {200
 100}}]
```

The following example creates a geo_mask with a region defined by shapes on a layer, merged.

```
prompt> create_geo_mask [get_layers M1] -merge
```

---

create_grid

Creates a new user or block grid.

Syntax

```
collection create_grid
[-pg_strategy PG_strategy]
[-layers layers]
[-site_rows rows]
[-site_arrays arrays]
[-x_step step]
[-y_step step]
[-x_offset offset]
[-y_offset offset]
[-orientations allowed_orientations]
[-type block | user]
grid_name
```

Data Types

PG_strategy	string
layers	collection
rows	collection

Feedback

```
arrays                collection
step                  float
offset                float
allowed_orientations  list
grid_name             string
```

Arguments

`-pg_strategy` *PG_strategy*

Specifies the name of the PG strategy to use when creating the block grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid pitches and offsets from the PG strategy. It is mutually exclusive with any option for manual block grid.

`-layers` *layers*

Specifies the tech layers to consider within the PG strategy. This option is applicable only for auto-derived block grid creation. A PG strategy might involve many routing layers. By default, all the layers in the specified PG strategy are used to derive the grid. If *-layers* is specified, only the specified layers in the PG strategy are used. This option is mutually exclusive with any option for manual block grid.

`-site_rows` *rows*

Specifies the site rows to be considered in creating the grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid's pitches and offsets from the given site rows. The specified site rows must be uniform and of the same type of unit site def. This option is mutually exclusive with any option for manual block grid.

`-site_arrays` *arrays*

Specifies the site arrays to be considered in creating the grid. This option is applicable only for auto-derived block grid creation. The tool derives the grid's pitches and offsets from the given site arrays. This option is mutually exclusive with any option for manual block grid.

`-x_step` *step*

Specifies the grid pitch in the x-direction. The default pitch is the litho grid pitch of the design. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

`-y_step` *step*

Specifies the grid pitch in the y-direction. The default pitch is the litho grid pitch of the design. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

Feedback

`-x_offset` *offset*

Specifies the grid offset from the design origin in the x-direction. The default offset is 0. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

`-y_offset` *offset*

Specifies the grid's offset from the design origin in the y-direction. The default offset is 0. This option is applicable for both user grid and block grid creation. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid.

`-orientations` *allowed_orientations*

Specifies the allowed orientations for any associated block instance of the created block grid. This option is applicable only for block grid creation. Specifies one or more of: R0, MX, MY, R180. By default, all four orientations are allowed. This is an option for manual block grid and is mutually exclusive with any option for auto-derived block grid. The allowed orientations of an auto-derived block grid are derived automatically from the PG strategy, layer, and site rows.

`-type block | user`

Specifies the type of grid to be created. By default a block grid is created. The *-type* option has two possible values: *block* for block grid, or *user* for user grid.

grid_name

Specifies the name of the grid to be created.

Description

This command creates a new grid. Two grid types are supported: block and user. The block grid can be used to tune block locations with commands such as *shape_blocks*, or by editing the layout in the GUI.

Use the *set_block_grid_references* command to associate the grid with a block reference design. Snapping the block instances to the block grid is done automatically inside the *shape_blocks* command and when editing the layout in the GUI with the snap setting. You can also use the *snap_cells_to_block_grid* command to snap block instances to the block grid.

Examples

The following example creates an auto-derived block grid named gr1 from patterns on layers M4 and M5 of PG strategy s1.

```
prompt> create_grid -pg_strategy s1 -layers [get_layers {M4 M5}] gr1
```

Feedback

The following example creates manual block grid named gr2 with pitch of 20 microns in the y-direction. All associated block instances must be placed in orientation R0, or flipped around the y-axis.

```
prompt> create_grid -y_step 20 -orientations {R0 MY} gr2
```

The following example creates a user grid named ug1 with a pitch of 10 microns in both x- and y-directions at an offset of 12 microns in the x-direction.

```
prompt> create_grid -type user -x_step 10 -y_step 10 -x_offset 12 ug1
```

---

create_group

Creates a group object in the current design.

Syntax

collection *create_group*

```
[-name group_name]
[-allow_duplicate_names]
[-type collection | set]
[-remove_when any_member_removed | empty | no_auto_removal | one_member]
[-shaping]
[object_list]
```

Data Types

group_name	string
object_list	list

Arguments

`-name group_name`

Specifies the name of the group. By default, the command generates a name automatically and uses the prefix GROUP_0, GROUP_1, and so on for new groups.

Feedback

`-allow_duplicate_names`

Allows duplicate group names in the design. When a new group is created with the *-allow_duplicate_names* option, the tool allows other groups to be created with the same name.

By default, the tool ensures that group names are unique in the design. When a new group is created, the tool validates that no other group has the same name and ensures that no other group is ever assigned the same name.

`-type collection | set`

Sets the type of the group. By default, the type is *set*.

A member of the group can appear only one time in a *set* type. A member of the group can appear multiple times in a *collection* type group.

`-remove_when any_member_removed | empty | no_auto_removal | one_member`

Specifies when the group should be automatically removed from the design, based on the removal of member objects in the group.

- any_member_removed: Remove the group when any member object is removed from the group.
- empty: Remove the group when the last member from the group is removed.
- one_member: Remove the group when only one member is left in the group after removing a different member.
- no_auto_removal: Never remove the group automatically.

By default, the *no_auto_removal* argument is used.

`-shaping`

The -shaping argument creates the group as a shaping group. Shaping groups must be sets and may only contain shapeable objects (voltage areas, move bouds, cells, and shaping groups). This argument is mutually exclusive with -repelling.

`-repelling`

The -repelling argument creates the group as a repelling bound group. Repelling bound groups must be sets and remove when empty. Furthermore, they may only contain cells. This argument is mutually exclusive with -shaping.

`object_list`

Specifies the objects to be added to the group.

Feedback

Description

The *create_group* command creates a group object. You can use a group object to implement a general purpose collection of design scoped supported objects. You can bundle these design scoped objects in a group and then can use as per the requirement.

Objects from the same design can be added to groups with the *add_to_group* command, and removed with the *remove_from_group* command. An object can belong to any number of groups at a time. Removing an object from a group does not remove the object from the design, however removing an object from the design automatically removes it from its containing group. Group nesting is permitted, so groups can contain other groups as member object, however cyclic relationship is not permitted between two groups so two groups cannot be member to each other.

This command returns the group as a single element collection, an empty string if it fails, or a Tcl error if there is a command syntax error.

Examples

The following example creates a group named "group1", which is automatically removed when its first member object is removed.

```
prompt> create_group -name "group1" -remove_when any_member_removed
{group1}
```

The following example creates a group named "group2" and adds the "CornUR" cell to the group.

```
prompt> create_group -name group2 [get_cells CornUR]
{group2}
```

---

create_group_repeaters_guidance

Creates net groups using the smart net grouping algorithms.

Syntax

status *create_group_repeaters_guidance*

Feedback

```
-nets collection_of_nets | -reset
[-group_spacing group_spacing_in_um]
[-exclude_pin_port]
[-ignore_layers]
[-max_nets_in_group number_of_nets_in_group]
[-number_of_interleaving_groups number]
```

Data Types

collection_of_nets	collection
group_spacing_in_um	float
number_of_nets_in_group	integer
number	integer

Arguments

`-nets` *collection_of_nets*

Specifies multiple nets for adding group repeaters. This option is required.

`-reset`

Clears all net group attribute marking on the nets and removes the cells, also resets net group ID to 0. This option and the *-nets* option are mutually exclusive.

`-group_spacing` *group_spacing_in_um*

Specifies the maximum spacing between routes to be in a group. The default is twice of site height. This option is optional.

`-exclude_pin_port`

Ignores the driver and load pins when grouping nets. With this option, signal direction in a net group might not be the same.

`-ignore_layers`

Ignores the routing layers when grouping nets. With this option, nets in the same group might not route on the same layer.

`-max_nets_in_group` *number*

Specifies the maximum number of nets in a group. During automatic net grouping, when the number of nets in a group exceeds the specified number, the nets are split into the separate groups.

`-number_of_interleaving_groups` *number*

Specifies the number of interleaving groups. With this option, the command separates the nets in a net group into a specified number of interleaving net groups. For example, if *-number_of_interleaving_groups* is 2, one net group are separated into 2 interleaving net groups. For example, without this option, 3 net groups are created. The net group IDs are {0 1 2}. With

Feedback

-number_of_interleaving_groups 2, 6 net groups are created. The net group IDs are {0 1 2 3 4 5}.

Description

This command creates the net groups based on their routing topology, signal direction, and routing layers. The net group IDs are set by net attribute *eco_net_group_id*.

Examples

The following command groups the specified nets into groups with default spacing, considering signal directions and routing layers:

```
prompt> create_group_repeaters_guidance -nets nets
```

When grouping nets, the following command specifies the maximum spacing between the routes, and ignores the driver and load pins of the nets:

```
prompt> create_group_repeaters_guidance -nets -group_spacing 5 \\
         -exclude_pin_port
```

The following command clears all net group attribute marking on the nets and removes the cells, also resets the net group ID to 0:

```
prompt> create_group_repeaters_guidance -reset
```

The following command performs net grouping and further separates each group into 2 interleaving groups:

```
prompt> create_group_repeaters_guidance -nets nets
 -number_of_interleaving_groups 2
```

See Also

- add_group_repeaters

---

create_hdl2upf_vct

Defines a value conversion table that can be used to convert HDL logic values into UPF net state type values. This command is supported only in UPF mode.

Syntax

status *create_hdl2upf_vct*

```
vct_name
-hdl_type {vhdl|sv [typename]}
-table {{from_value to_value}*}
```

Feedback

Data Types

```
vct_name      string
typename      string
from_value    HDL logic value
to_value      UPF state type value
```

Arguments

vct_name

The value conversion table name.

`-hdl_type {vhdl|sv [`*typename*`]}`

The HDL type for which the value conversions are defined.

`-table {{`*from_value to_value*`}*}`

A list of the values of the HDL type to map to UPF state type values.

Description

The *create_hdl2upf_vct* command defines a value conversion table from an HDL logic type to the state type of the supply net value when that value is propagated from HDL port to a UPF supply net. It shall provide a conversion for each possible logic value that the HDL port can have. The *create_hdl2upf_vct* command does not check that the set of HDL values are complete or compatible with any HDL port type.

The *vct_name* argument provides a name for the value conversion table for later use with the *connect_supply_net* command (see 6.6).

The *-hdl_type* argument specifies the HDL type for which the value conversions are defined. This information allows a tool to provide completeness and compatibility checks. If the typename is not one of the language's predefined types or one of the types specified in the next paragraph, then it shall be of the form library.pkg.type.

The following HDL types shall be the minimum set of types supported. An implementation tool may support additional HDL types:

-) VHDL
  - Bit, std_[u]logic, Boolean
  - Subtypes of std_[u]logic
- SystemVerilog
  - reg/wire, Bit, Logic

The *-table* option defines the 1:1 conversion from HDL logic value to the UPF partially on and on/off states. The values are consistent with the HDL type values.

Feedback

For example:

- When converting from SystemVerilog logic type, the legal values are 0, 1, X, and Z.
- When converting from SystemVerilog or VHDL bit, the legal values are 0 or 1.
- When converting from VHDL std_[u]logic, the legal values are U, X, 0, 1, Z, W, L, H, and -.

The conversion values have no semantic meaning in UPF. The meaning of the conversion value is relevant to the power-aware HDL model to which the supply net is connected.

See Also

- create_upf2hdl_vct
- connect_supply_net

---

create_icovl_cells

Inserts in-chip overlap (ICOVL) cells for layer-to-layer alignment control.

Syntax

status *create_icovl_cells*

```
-lib_cells libcells
[-partitions inst_pair]
[-xy_grid int_pair ]
[-type backend | frontend]
[-tcd_spacing distance ]
[-other_cell_spacing distance]
[-icovl_spacing distance]
[-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90
[-check_only]
[-bbox {{x1 y1} {x2 y2}} ]
[-placement_blockage_extension extension]
[-routing_blockage_extension extension]
[-routing_blockage_layers {start_layer end_layer}]
[-over_icovl_routing_guide_extension extension]
[-over_icovl_routing_guide_layers {start_layer end_layer }]
```

Data Types

```
int_pair     2 integers
libcells     list of library cells
inst_pair    list of instance pairs
distance     float
x1           float
y1           float
x2           float
```

Feedback

```
y2           float
extension    float
start_layer  layer
end_layer    layer
```

Arguments

`-xy_grid` *int_pair*

Divide the chip area into boxes based on specified grids. Insert one icovl cell to each grid box if possible. Either us -xy_grid or -partitions option to specify how icovl cells should be inserted

`-lib_cells` *libcells*

Specifies the collection of ICOVL library cells to insert as a set.

`-partitions` *inst_pair*

Specifies a list of integer pairs that describe how the insertion area should be divided and specify the number of ICOVL sets that should be inserted. The first number of each integer pair is the relative size of the insertion area. The second number of each pair is the number of ICOVL sets for this part. For example, the following option

```
-partitions {{1 1} {7 5} {2 2}}
```

specifies that insertion area should be vertically divided into 1+7+2=10 parts. The first partition is equal to 1 part and should contain one set of ICOVL cells. The second partition is equal to 7 parts and should contain 5 sets of ICOVL cells. The third partition is equal to 2 parts and should contain 2 sets of ICOVL cells.

`-type backend | frontend`

Specifies the type of ICOVL insertion. Valid values are *frontend* or *backend*. Use this option to indicate you are doing frontend or backend ICOVL insertion.

`-tcd_spacing` *distance*

Specifies the minimum distance between ICOVL and testkey critical dimension (TCD) cells.

`-other_cell_spacing` *distance*

Specifies the minimum distance between ICOVL cells and cells other than testkey critical dimension (TCD) and ICOVL cells.

`-icovl_spacing` *distance*

Specifies the spacing between ICOVL cells.

Feedback

`-orientation R0 | R90 | R180 | R270 | MX | MXR90 | MY | MYR90`

Specifies the front-end ICOVL cell orientation. Valid values are R0, R90, R180, R270, MX, MXR90, MY, MYR90.

`-check_only`

Checks the current design for front-end ICOVL violations based on rules specified in other options. An error message is issued for each violation.

`-bbox` *{{x1 y1} {x2 y2}}*

Specifies an insertion area in which to insert the ICOVL cells. This area will be divided into the specified window size for ICOVL insertion. By default, the die area is the insertion area.

`-placement_blockage_extension` *extension*

Specifies the extension size of placement blockage for ICOVL cells in microns. The blockage will extend beyond ICOVL boundary by the size specified. When specified, the tool creates placement blockages around new ICOVL cells. Note that this placement blockage does not prevent existing cells from placement within the blockage. To keep other cells outside the placement blockage, apply a cell spacing rule that is greater or equal to placement blockage size. By default, no placement blockage extension is applied.

`-routing_blockage_extension` *extension*

Specifies the extension size of routing blockage for ICOVL cells in microns. The blockage will extend beyond ICOVL boundary by the specified size. Routing blockages will be created on layers specified in *-routing_blockage_layers*. You must specify the *-routing_blockage_layers* option together with the *-routing_blockage_extension* option. This option is not required.

`-routing_blockage_layers` *{start_layer end_layer}*

Specifies the metal routing blockage layers. Routing blockages will be created on each metal layer from *start_layer* to *end_layer*. To specify only one routing blockage layer, use the same layer name for both *start_layer* and *end_layer*, for example, *-routing_blockage_layers {M3 M3}*. This option is not required.

`-over_icovl_routing_guide_extension` *extension*

Specifies the size (in micron) for special over-ICOVL cell route guides to be created on ICOVL cells. Over-ICOVL routing guides are created over ICOVL cells and extend outward from an ICOVL cell edge by the specified size. This option must be used together with the *-over_icovl_routing_guide_layers* option. This option is not required.

Feedback

`-over_icovl_routing_guide_layers {start_layer end_layer }`

Specifies the metal layers for special over-ICOVL cell routing guides to be created on ICOVL cells. To specify a single metal layer for the routing guide, use the same layer name for both start_layer and end_layer, for example, *-over_icovl_routing_guide_layers {M3 M3}*. This option is not required.

Description

This command inserts in-chip overlap (ICOVL) cells into the current design. ICOVL cells are used for layer-to-layer alignment control during fabrication to improve yield. ICOVL cells are included on one layer with different DP masks. ICOVL cells are inserted into the core area of the design. The core area is divided into partitions, where each partition can have a different size and require a different number of ICOVL cell sets. ICOVL cells are macros and are not allowed to overlap any other cells.

This command is used for both frontend and backend ICOVL cell insertion. Frontend ICOVL cells are inserted during the floorplanning stage, after macro and frontend TCD cell placement. Backend ICOVL cells are inserted after power planning.

Examples

The following command inserts frontend ICOVL cell sets. Each ICOVL sets has 3 ICOVL cells: icovl_m1, icovl_m2, and icovl_m3. The core area is divided into 4 partitions in the y-direction. From bottom to top, the first partition equals 10 percent of the core area and needs 1 ICOVL sets. The 2nd partition equals 30 percent and needs 2 ICOVL sets. The 3rd partition is 20 percent and needs 2 ICOVL sets, and 4th partition is 40 percent and needs 3 ICOVL sets. Routing blockages will be created on metal layers from metal1 through metal6. ICOVL cells will be placed in R0 orientation.

```
prompt> create_icovl_cells -lib_cells {icovl_m1 icovl_m2 icovl_m3} \\
   -partitions { {1 1} {3 2} {2 2} {4 3}} \\
   -placement_blockage_extension 20.0 \\
   -routing_blockage_extension 3.0 \\
   -routing_blockage_layers { metal1 metal6} \\
   -icovl_spacing 10.0 \\
   -tcd_spacing 5.0 \\
   -other_cell_spacing 5.0 \\
   -orientation R0 \\
   -type frontend
```

Below example will divide chip area into 4 x 5 grids and insert one icovl cell into each grid if possible.

```
prompt> create_icovl_cells \\
-lib_cells ICOVL_CELL  \\
-tcd_spacing 90 \\
-xy_grid { 4 5}
```

---

create_if_statement

Creates 1 RTL if statement.

Syntax

collection *create_if_statement*

```
-test test
-then then
[-else else]
[-module module | -cell cell]
[-scope scope]
```

Data Types

```
test                collection
then                collection
else                collection
module              collection
cell                collection
scope               collection
```

Arguments

`-test test`

Specifies test expression statement for the if else statement.

`-then then`

Specifies the if statement for the if else statement.

`-else else`

Specifies else statement for the if else statement.

`-module module`

Specifies the module to create the if else statement in. This option is mutually exclusive with the *-cell* option.

`-cell cell`

Specifies the cell to create the if else statement in. This option is mutually exclusive with the *-module* option.

Feedback

`-scope` *scope*

Adds the newly created if statement in the scope provided by the RTL statement.

Description

This command creates an if else object that represents an RTL if else statement. The if else statement is created in the specified module or cell. If the *-module* or *-cell* option is not specified, the if else statement is created in the current instance.

Examples

The following example creates 1 if else statement in the given instance with the test expression named *RTL_EXPRESSION_8]f* and the statement named *RTL_ASSIGNMENT_14*.

```
prompt> create_if_statement -test [get_statements u1/u1/RTL_EXPRESSION_8]
 \\
   -then [get_statements u1/u1/RTL_ASSIGNMENT_14] \\
   -cell u1/u1 {"u1/u1/RTL_IF_ELSE_85"}
```

See Also

- get_statements
- remove_statements

---

create_interconnect_groups

Identifies interconnect groups based on backward path tracing from input loads.

Syntax

```
status create_interconnect_groups
-loads pin_port_list
[-lib_cell_input pin_name]
[-lib_cell_output pin_name]
```

Data Types

pin_port_list	collection
pin_name	string

Arguments

`-loads` *pin_port_list*

Specifies list of pin or port as load.

Feedback

`-lib_cell_input` *pin_name*

Specifies pin name when the lib cell has multiple input pins. The default is D.

`-lib_cell_output` *pin_name*

Specifies pin name when the lib cell has multiple output pins. The default is Q.

Description

This command traces paths from input loads through combo gates, registers and repeaters to driver pins on macro cells, and output interconnect grouping information.

```
Rules for interconnect groups:
1. Supernet bus definition (start point to end point)
• Macro pin to combo gate
• Combo gate to combo gate
• Combo gate to load

2. Identify type for supernet
• Macro pin to combo gate
     Consider buffer.
• Combo gate to combo gate
     If there is register in between, consider buffer, otherwise, ignore
 buffer.
     If there is only buffer in between, type is empty.
• Combo gate to load
     Consider buffer.

3. Grouping rule
• Group driver by macro and type.
• Group load by type only.
• Group combo gate according to one of driver macro and type and level of
 combo gate.
• Group supernet by start point, so supernet group depends on driver
 groups and combo gate groups.

4. The command creates supernet for each group of driver groups and combo
 gate groups.

The command outputs the group info as follows.
4 types of list of collection:
• Drivers: eco_driver_groups
     A list of driver groups, and a driver group is a list of collection
 of drivers.
     Drivers in one collection belong to same hard/soft macro.
     e.g.  { $HM1_33 $HM2_33 $HM3_33 $HM4_36 $HM5_36 $HM6_36 }
• Loads: eco_load_groups
     e.g.  { $loads_69}
• Combo gates: eco_combo_gate_groups
     e.g.  { $Combo_33 $Combo_36 }
• Supernets: eco_supernet_groups
     e.g.  { $sn_HM1_33 $sn_HM2_33 $sn_HM3_33 $sn_HM4_36 $sn_HM5_36
 $sn_HM6_36 $sn_Combo_33 $sn_Combo_36}
```

Feedback

```
3 new attributes:
• sn_type: a new attribute for pin and port.
     Record type on start point and end point for a supernet.
     The type is a string to represent object types one supernet pass
 through from start point to end point. e.g. LRSSSC
     L: load
     S: sequential cell
     R: repeater (buf / inv)
     C: combo gate
     M: macro cell
• sn_point: a new attribute for pin and port.
     Record start point or end point for a supernet.
     For start point, it records its end point, while for end point, it
 records its start point.
• combo_level: a new attribute for cell.
     Record traversal level of combo gate from load.

The Flow is like below.
• Create interconnect groups
     create_interconnect_groups -loads -lib_cell_input d -lib_cell_output
 q
• Place combo gates
• Auto repeater grouping for each supernet group and create interconnect
 plan accordingly.
foreach one_sn_group $::eco_supernet_groups {
   // create a supernet bundle,  e.g. bundle for supernets $sn_Combo_33
   create_bundle -name bundle_$idx  [get_supernets $one_sn_group ]
   // get target cells to do grouping,  registers and repeaters
   set target_cells [get_attribute [get_supernets $one_sn_group ]
 transpare_cells]
   // get unique lib cells to do grouping
   set target_lib_cells [get_lib_cells -of [get_cells $target_cells]]

   // The target cells are grouped automaticlly and the output
 ”crg_created_group_ids” is a list of list which including list of path
 groups.
   // And the order in each list is from load to driver.
   // The cell order in related path groups are aligned.
   create_repeater_groups -lib_cell_input d -lib_cell_output q
 -supernet_bundles {bundle_$idx} -lib_cells $target_lib_cells
   // For one supernet group, it includes one list path groups.
   // e.g. {{1 2 3 4}}
   foreach path_groups $::crg_created_group_ids {
       // create interconnect plan by user based on query command
   }
}
```

Examples

The following examples show the usages of command.

Feedback

```
prompt> create_interconnect_groups -loads [get_ports o_bus*]
 -lib_cell_input d -lib_cell_output q
```

---

create_interior_tap_walls

Creates a tap wall inside a boundary edge of a core area, hard macro, soft macro, hard placement blockage, or nondefault voltage area. The boundary typically already contains boundary cells.

Syntax

status *create_interior_tap_walls*

```
-lib_cell cell_name
-side  top | bottom | left | right
[-x_spacing spacing]
[-bbox  coordinates
[-prefix cell_prefix]
[-orientation  R0 | R180 | MX | MY]
```

Data Types

```
cell_name       string
spacing         float
coordinates     list
cell_prefix     string
```

Arguments

`-lib_cell` *cell_name*

Specifies the library reference cell to be used as a tap cell. You must specify a single library cell. This is a required option.

`-side top | bottom | left | right`

Specifies the side on which to create a tap wall. You must specify a single side. This is a required option.

`-x_spacing` *spacing*

Specifies the spacing between tap cells in microns for horizontal tap walls. This option is ignored for vertical tap walls.

Feedback

If the specified value is not an integer multiple of the site width, the tool rounds it down to a multiple of the site width. If the value is less than the width of the tap cell, the tool uses zero spacing.

The default is 0, and there is no space between the tap cells.

`-bbox` *`coordinates`*

Specifies the rectangular tap insertion region in microns. Specify the rectangle as a list of four coordinates, {{llx lly} {urx ury}}, which represents the lower-left and upper-right corners of the rectangle.

A tap wall is created along the longest edge of the core boundary, macro, hard placement blockage, or nondefault voltage area encompassed by the rectangular region. The command issues an error message if it cannot find an edge.

If you do not specify this option, the command creates an interior tap wall along each edge of the specified side.

`-prefix` *`cell_prefix`*

Specifies the prefix for the created tap cells.

When you use this option, the command uses the following naming convention for the inserted tap cells:

`<cell_prefix>__<lib_cell>_R#_C#_number`

By default, no prefix is added and the tool uses the following naming convention for the inserted tap cells:

`tapfiller__<`*`lib_cell`*`>_R#_C#_number`

`-orientation R0 | R180 | MX | MY`

Specifies the orientation of the placement of the tap cells.

By default, the orientation follows the orientation of the row or site.

Description

This command adds an interior tap wall to the design. A tap wall is a row or column of identical tap cells placed linearly. A tap cell is a special cell with a well tie, substrate tie, or both. Tap cells are typically used when most or all standard cells in the library do not contain substrate or well taps.

Interior tap wall placement follows the usual rules of standard cell placement and snaps the tap cells to rows and sites. The command does not insert tap cells if the rows or sites are missing.

Feedback

If you specify the *-bbox* option, the command creates a single tap wall along the longest edge segment. If the edge segment does not contain a corner, the tap wall aligns to the left or bottom of the tap insertion region. If the edge segment contains one corner, the tap wall aligns to the corner. If the edge segment contains two corners, the tap wall aligns to the left or bottom of the tap insertion region. When the edge segment contains two corners for a horizontal wall, the gap between the last cells the might be shortened.

Obstructions such as placement blockages, fixed cells, and macros might prevent successful placement of the tap cells, resulting in incomplete or missing tap walls.

The command marks the inserted tap cells as fixed.

Examples

The following example creates tap walls along the inside of all edges on the top side of the core area.

```
prompt> create_interior_tap_walls -lib_cell myLib/Cell1 -side top
```

---

create_interposer_routeplan

Places vias and routes for an interposer design.

Syntax

string *create_interposer_routeplan*

```
[-interposer_style default | fpga | single_hbm | vertical_routing]
[-pattern_file file_name]
```

Data Types

```
file_name    string
```

Arguments

```
-interposer_style default | fpga | single_hbm | vertical_routing
```

Specifies the style of the design. Based on the selection, the tool will process different types of pattern files and perform different actions. If this option is not specified, the *default* style is used.

Feedback

`-pattern_file` *file_name*

Specifies a pattern file that contains information on how to place interposer vias and routes. The keywords supported in the pattern file depend on the *-interposer_style* option specified.

The pattern file contains one or more sections, where each section starts with a keyword followed by a pair of curly brackets. Inside the curly brackets, one or more constraints are specified. Each constraint is made of a pair of curly brackets which contains the information of the element. Comment lines begin with the pound sign (#) and inline comments begin with two forward slashes (//).

If the *default* style is chosen, the following sections and elements are supported:

The configuration section is specified by the *config* keyword and contains a *stack_level* specification and a *via_def* specification. The *stack_level* keyword is followed by a positive integer, where zero specifies that simple vias will be inserted and a positive integer specifies an additional number of stacked via levels. For example, {stack_level 1} specifies that the tool places the basic via and one additional level.

The *via_def* keyword is followed by a non-negative integer and a string. The integer represents the via level in the via stack and the string specifies the via reference, where the specified via reference is used to create new vias. If the integer following the via_def keyword conflicts with the level specified by stack_level, it will be ignored and the tool will issue a warning message. An example configuration section is given below which specifies a stacked via.

```
config {
  {stack_level 2}
  {via_def 0 via7}
  {via_def 1 via6}
  {via_def 2 via5}
}
```

In the config section, user can describe via arrays. Specifically, the orientation keyword specifies the orientation of the via w.r.t the via_def. It is followed by a string $orientation describing the orientation. The $bump_instance_name is optional. If it is used, the via configuration is only for the bump cell instance specified. Otherwise, it is the default and will be used for all bumps without individual via configuration information. The columns and rows keyword define the dimension of the via array. They are followed by positive integers. Similarly, they can have the optional $bump_instance_name.

```
config {
  {orientation $orientation  [$bump_instance_name]}
  {columns $positive_integer [$bump_instance_name]}
  {rows $positive_integer [$bump_instance_name]}
}
```

Feedback

It is important to note that, if a bump already has a via placed, which has a different configuration from that described by the pattern file, the existing via will not be changed. It is user's responsibility to remove the existing via before running the command with correct via configuration in the pattern file.

The design rule section, specified with the *drc* keyword, contains spacing rules for via insertion and placement. This section contains the *bump*, *peer*, *layer*, *via_def_name*, and *via_def_index* specifications. The *bump* keyword is followed by a floating point number that specifies the minimum distance between the base via and any bump in microns. The *peer* keyword is followed by a floating point number and specifies the minimum distance between the base vias. The *layer* keyword is followed by a layer name string and a floating point number, and specifies the minimum distance between the base via and a preroute on the specified layer. Only the top and bottom layers of the base via are relevant, all other layers are ignored. The *via_def_name* keyword is followed by a string and a floating point number, and specifies the minimum distance between the base via and the specified type of via. If the specified via def is the base via, this element provides the same functionality as that of the second type element. Otherwise, since the via on any lower metal level is inside the base via, the distance is measured between the edges of the vias inside of the base via. The *via_def_index* keyword is followed by non-negative integer and a floating point number, provides similar functionality to *via_def_name*, but specifies the via by using a level index instead of a via_def name. The base via is on level 0, lower level vias beneath the base via will have indexes of positive values. An example of the design rule section is given below.

```
drc {
  {bump 0.1}
  {peer 0.1}
  {layer AP 0.1}
  {via_def_name VIA34 0.2}
  {via_def_index 1 0.2}
}
```

The via count section, specified with the *count* keyword, contains the rule for the number of vias or stacked vias to add to the interposer. The *bump* keyword specifies that a base via might be added for each front-side bump of a net. The *flat_net* keyword specifies that at most a single base via can be added for the entire flat net. If any part of the flat net has been routed on the layer of the bump, the via location will be selected on a preroute. Otherwise, a bump will be selected for via insertion. The third possible keyword is *bump_share*. If this mode is selected, tool will try to insert an interposer via for each bump of the net. If at least one bump is added for the net, no error message will be issued. Namely, bumps can share an interposer via. If no via can be inserted, an error message will be issued. Note that the vias do not include existing ones. If there are interposer vias already in the design for all bumps of the net, no error

Feedback

message will be issued. If this section is not given, the default value is *bump*. An example of the via count section is shown below.

```
count {
  flat_net
}
```

The exclusion section, specified with the *exclusion* keyword, specifies that specific bump cells, nets, or reference cells should be ignored. The *bump* keyword is followed by a bump instance string. The specified bump cell instance is ignored. The *net* keyword is followed by a flat net string. The specified net is ignored. The *reference_cell* keyword is followed by a reference cell string. All bump instances of the specified reference cell are ignored for via insertion. By default, the tool processes the entire interposer design. An example of the exclusion section is given below.

```
exclusion {
  {bump BUMP_1}
  {net NET}
  {reference_cell REF_BUMP}
}
```

The inclusion section, specified with the *inclusion* keyword, specifies the part of netlist which the tool will process. Its format is identical to the exclusion section. All three keywords reference_cell, bump, net can be used. The inclusion and exclusion sections are mutually exclusive. An example of the inclusion section is given below.

```
inclusion {
  {bump BUMP_1}
  {net NET}
  {reference_cell REF_BUMP}
}
```

The location section, specified with the *location* keyword, contains location constraints for the new vias. This section contains the *x*, *y*, or *xy* keywords, specifying a horizontal coordinate, a vertical coordinate, both coordinates. The keyword is followed by the *relative* or *absolute* keyword. The *relative* keyword specifies values with respect to the center of the corresponding bump boundary box. The *absolute* keyword specifies values with respect to the interposer origin. The next field specifies one or two float values for the horizontal, vertical, or both coordinates. The optional last field specifies the bump instance name to use when applying the constraint. If there is no bump name, the constraint is applied to all bumps. An example of the location section is given below.

```
location {
  {x  relative 4      BUMP_1}
  {y  absolute 400    BUMP_2}
  {xy relative 2   2  BUMP_3}
}
```

Feedback

It is important to note that if you specify both horizontal and vertical coordinates for a bump, the tool places a via at the specified location as long as there is not a via already at the exact same location. Therefore, if you run the tool multiple times with different horizontal and vertical coordinates, many vias will be placed for the same bump. It is your responsibility to remove any redundant vias.

The exception section specified with the *exception* keyword, contains many special constraints. If the *default* design style is chosen, user can use *45degree* make the tool place a via close to a corner of the corresponding bump boundary box. Note that this feature is only applied when the bump is at a corner of the correspond net bounding box. Vias placed on nets will not be affected. Using this option will reduce the overall wirelength of the interposer routing.

```
exception {
  {45degree}
}
```

If the *default* design style is chosen, the tool only places interposer vias within the bounding box of the corresponding net. No vias can be placed if there is no enough area for a single via inside the bounding box. User can use *box_enlarge_value* in the exception section specified with the *exception* keyword in the pattern file to increase the area where interposer vias can be placed. Specifically, both dimension of the net bounding box is increased by the amount specified by *box_enlarge_value*. User can use *box_dimension_threshold* in addition to *box_enlarge_value*. If *box_dimension_threshold* is used, only any net bounding box whose dimension is less than the value specified will be increased. The following example enlarges all net bounding box areas whose dimension is less than 10 micron by 0.5 micron.

```
exception {
  {box_dimension_threshold 10}
  {box_enlarge_value 0.5}
}
```

The tool is able to report net routing order by generating text files containing sets of net names. User needs to use the keyword *report_shielding_groups* followed by net patterns. Only two patterns are supported as shown below. Nets routed in different layers will be grouped in separate files. The filenames are upper_ $index and lower_$index, corresponding to the two routing metal layers.

{report_shielding_groups interleave_4} {report_shielding_groups interleave_2}

If the *single_hbm* style is chosen, the following elements are supported. They are all inside the exception section. The keyword channel_direction describes the channel orientation.

{channel_direction vertical | horizontal}

Feedback

The routing width and spacing in the bump array region of the 3D channel are specified by the keyword wire_width and wire_spacing, respectively. The routing width and spacing in the middle section of the channel are the same unless they are changed by constraints of other keywords. The values following the keywords must be positive. User is responsible for the correctness of the values.

{wire_width $micron} {wire_spacing $micron}

In the default mode, bumps are cell instances. If bumps are simple shapes or terminals, users must set the layer of bump shapes in the pattern file as follows.

{bump_shape_layer $layer}

All bump shapes must be of the same size. Otherwise the tool will error out without performing routing. There cannot be both bump cells and bump shapes.

The keyword *via_bump_abutment* is a boolean constraint that determines the routing style produced by the tool. When it is set to true, all vias that connect the top RDL layer to any lower metal layer are placed with bump abutment. As a result, there is no need for RDL routing between vias and bumps. User can add a gap of a given distance between a via and the corresponding bump with the following constraint. The gap will be filled with route on RDL.

{via_bump_abutment_gap $micron}

When *via_bump_abutment* is true, the Manhattan double-Z style is chosen for the routing in the middle section of the 3D channel. The following keywords are used to specifies the route widths and lengths for the middle section routing. Particularly, the middle segment length is described by keyword midtrack_lengths. The routing width and spacing for the two routing segments perpendicular to the channel orientation are described by keyword midtrack_turn_width and midtrack_turn_spacing, respectively. The routing width and spacing for the middle section routing are described by keyword midtrack_width and midtrack_spacing, respectively.

{midtrack_lengths $micron} {midtrack_turn_spacing $micron} {midtrack_turn_width $micron} {midtrack_spacing $micron} {midtrack_width $micron}

It is possible to route each net of an 3D channel using different widths. Specifically, users can set three width values, for the two bump array regions and middle section of the channel, respectively. User specify the width and spacing in the *exception* section of the pattern file. The width values are set as follows.

{wire_width_upper_array $micron} {wire_width_lower_array $micron} {wire_width_mid_connector $micron}

Feedback

The upper and lower arrays refer to the top and bottom bump array regions, respectively, if the channel is vertical. The upper and lower arrays refer to the right and left bump array regions, respectively, if the channel is horizontal. Alternatively, users can use the following.

{wire_width_right_array $micron} {wire_width_left_array $micron}

If keyword *via_bump_abutment* is false, the tool may not place vias with bump abutment. The vias are aligned to the corresponding routing. The gap between the via and bump bounding box is specified by the keyword rdl_via_offset. The gap length is measured along the channel direction. The vias are always placed above or on the right side of the corresponding bumps, for vertical and horizontal channels, respectively. When keyword *via_bump_abutment* is false, the 45-degree Z-style is chosen for the routing in the middle section of the 3D channel. The keyword middle_turn_offset specifies the length of top or right segment routing, for vertical and horizontal channels, respectively.

{rdl_via_offset $micron} {middle_turn_offset $micron}

The value of rdl_via_offset must be non-negative unless the following keyword is also used.

{via_under_bump}

User can add a spacing control to specify the gap between a bump-access via and its neighboring track. This space is applied to shapes on the upmost routing layer only. Namely, the space between the boundary box of a via and the boundary of a routing shape must be at least equal to the specified value regardless of the layer of the routing shape. The format is given below.

{rdl_via_spacing $micron}

When keyword *via_bump_abutment* is true, user can choose the 45-degree Z-style for the routing in the middle section of the 3D channel using the following keyword and value string.

{middle_pattern 45_degree}

If the bump array alignment offset is larger than the middle channel length, a 5-stage routing mode must be used for middle section of the 3D channel. This routing is selected with the following keyword in the pattern file.

{mid_routing_switch_direction}

Three paramenters are used to describe the 5-stage routing shape in the middle channel area and specified using the following keyword. The perpendicular track locations is related to the boundary stubs near the upper bump array. The upper and lower offset refer to the stubs at the boundary of bump arrays, respectively, which are defined based on the 3D channel orientation. They are

Feedback

not related to the vertical coordinates of the bump arrays. The default values are 60 microns, 30 microns and 30 microns, respectively. The constraints are applied to the lower metal routing if two layer routing is selected. The high metal routing are built according to the layer track offset style, which can be inline, staggered_before and staggered_after.

{mid_routing_switch_direction_gaps $perpendicular_route_location $perpendicular_mid_switch_upper $perpendicular_mid_switch_lower}

The column or row of the 3D channel can be identified in two ways. First, user can specify two bounding boxes, at the two ends of the channel. Bumps inside of the two boxes are routed as part of the channel. The keyword for channel bounding boxes is bump_array_box, followed by the corner coordinates of the two boxes. If users want to exclude any bumps inside either box, keyword excluded_bump_in_box must be use for each of the excluded bumps.

{bump_array_box {llx_box1 lly_box1} {urx_box1 ury_box1} {llx_box2 lly_box2} {urx_box2 ury_box2}} {excluded_bump_in_box $bump_name}

The second way to describe a channel is to use the inclusion section to specify all the nets that connect two bumps. User also needs to describes any addition bumps in the channel that are not connected to any nets using the keyword float_bump. Furthermore, if any bump of the channel are connected to components other than front-side micro bumps, the corresponding net needs to be described using the keyword 2pin_through_net. Both float_bump and 2pin_through_net are in the exception section.

{float_bump $bump_name} {2pin_through_net $net_name}

Normally bumps must be placed in an array of a regular pattern as defined by the corresponding 3D standards. In case user needs to route a channel in which bumps are placed at irregular locations, the following keyword must be added in the exception section of the pattern file:

{non_hbm_bump_pattern}

Two metal layers must be specified for 3D routing. The keywords are right_array_routing_layer, left_array_routing_layer, upper_array_routing_layer and lower_array_routing_layer. The keywords are followed by the corresponding layer names. The bump arrays at the two ends of the channel are divided into two regions. The bumps in the top or right region are routed using the layer specified with upper_array_routing_layer or right_array_routing_layer. The other bumps in the bottom or left region are routed using the layer specified with lower_array_routing_layer or left_array_routing_layer.

{lower_array_routing_layer $layer_name} {upper_array_routing_layer $layer_name} {left_array_routing_layer $layer_name} {right_array_routing_layer $layer_name}

Feedback

User can route the 3D channel using a single metal layer. The layer is specified using keyword routing_layer followed by the layer name. If this keyword is used, other layer specification information will be ignored. In the single layer 3D routing mode, the tool will detect any pre-routes or vias on the routing layer in the bump array region to avoid routing rule violations. This feature is not intended for incremental 3D routing. This feature is not intended for iterative routing quality improvement. User cannot select a subset of remaining unrouted nets and perform 3D routing. The pre-existing shapes are expected to be small and sparsely placed.

{routing_layer $layer_name}

If pre-routes and/or vias exist in the middle section of the 3D channel, they are ignored during 3D routing. As a result, routing rule violations may not be prevented. The tool will issue warning messages in such a situation, however. Users are recommended to remove those vias and/or pre-routes. If these vias and/or pre-routes cannot be removed, users need to add new routing constraints or modify existing constraints to resolve any violations.

The routes created by the tool are called stubs. They are used in conjunction with a guidance file during the subsequent RDL routing step. There are two kinds of stubs. The boundary stubs are placed at the boundaries between the bump array regions and the middle routing region of the channel. The routing stubs are inside of the bump array region. The length of stubs can be specified by the keyword boundary_stublength and routing_stublength, respectively.

The default routing stub length is equal to the length of a bump access via or the dimension of any preroute discovered, with the minimal value as the routing pitch. If bump access vias are long, for instance when a via array is used, the stub length might be too long, leading to bad routing result. A key word short_stub can be used in the pattern file to reduce the routing stub length to half of the default value, with minimal value as one and one-half of wire width.

The locations of the boundary stubs can be controlled by the keyword boundary_stub_corners. Specifically, if user choose the keyword auto_align after boundary_stub_corners, the boundary stub bounding box will be align to the corresponding bump array box. The offsets along the channel direction for the upper and lower end of the channel, high_offset and low_offset, can be given optionally. If not given, the offset values are derived by the tool based on bump dimension and wire routing pitch. Alternatively, user can specify the exact locations for the stubs. The location can be described using the absolute coordinates or the relative offset values with respect to the bump array box as follows.

{boundary_stub_corners auto_align [high_offset low_offset]}
{boundary_stub_corners absolute | relative x_high y_high x_low y_low}

Feedback

The boundary stubs are placed on two routing layers. The stubs on the two layers can overlap or be placed in an interleaved pattern. The keyword that controls the stub pattern is stub_alignment_type. User can choose three pattern as given below. The stub on the lower metal layer is used as the reference.

{stub_alignment_type inline | staggered_before | staggered_after}

When the keyword *via_bump_abutment* is false, the locations of boundary stubs can be set to any desired values although the same patterns must be used for both routing layers. Specifically, the gaps between pairs of adjacent boundary stubs are set using keyword boundary_stub_gaps followed by a list of values in microns. User must specify at least 23 values. Values more than 23 are ignored.

{boundary_stub_gaps gap_1 gap_2 ... gap_23}

If a repeating pattern exist, the following concise format can be used, in which the repeating pattern is specified in a pair of curly brackets, with the repeating number before.

{boundary_stub_gaps repeat_times {gap_1 gap_2 ... } }

Although the boundary stubs of high metal layer must be the same as that of the lower metal, the stub locations can be shifted by an offset w.r.t those of the lower metal layer. The offset is given using keyword boundary_stub_staggered_offset. The value is perpendicular to the channel direction. It can be either positive or negative. If the offset is the same for both sides of the 3D channel, a single value is provided as below.

{boundary_stub_staggered_offset $value}

If the offset for the upper/right side is different from that of the lower/left side, two values are provided as below.

{boundary_stub_staggered_offset $upper_right_value $lower_left_value}

If the stub spacing values need to be different for the two bump arrays and/or the middle section of the 3D channel, the spacing values are set using the following keywords. The $gap_list has the same format as that of keyword *boundary_stub_gaps*. *boundary_stub_gaps_high* is used for the top bump array or right bump array. *boundary_stub_gaps_low* is used for the bottom bump array or left bump array.

{boundary_stub_gaps_high $gap_list} {boundary_stub_gaps_low $gap_list} {boundary_stub_gaps_middle $gap_list}

The keyword *three_zone_routing_rule* should be used with *boundary_stub_gaps_middle* so that the gaps defined by *boundary_stub_gaps_middle* is used for the entire middle section of the 3D channel.

Feedback

{three_zone_routing_rule}

The keyword *bump_index_pair* is used in combination with keyword *boundary_stub_gaps*. User uses *bump_index_pair* to specify which two nets will be routed next to each other. The format is given below.

```
{bump_index_pair
{{rowIndex_0_0 column_index_0_0} {rowIndex_0_1 columnIndex_0_1}}
{{rowIndex_1_0 column_index_1_0} {rowIndex_1_1 columnIndex_1_1}}
{{rowIndex_N_0 column_index_N_0} {rowIndex_N_1 columnIndex_N_1}}
}
```

The orientation of bump rows is defined as the orientation perpendicular to the channel orientation. The first row and the first column are with the least coordinate value. If the bump is missing at the location specified by the row and column indexes, the bump pair is ignored. If the bump at the location specified by the row and column indexes is not connected to any net, the bump pair is also ignored.

User can specify two pairs of nets and ask the tool to route these four nets in a special manner. Specifically, either pair of nets are routed together. There is no other net routed between the two nets in the pair. In addition, the two pairs are routed on two different layers. The footprint of the two pairs overlap. Only two-layer routing is supported for differential routing. The different pairs are specified using *differential_nets* as follows. Note that the bumps of each pair of nets need to be close to ensure a routable result.

{differential_nets {$netName0_pair0 $netName1_pair0} {$netName0_pair1 $netName1_pair1} }

When the keyword *via_bump_abutment* is true, the Manhattan double-Z style is chosen for the routing in the middle section of the 3D channel. User can add shielding to the the middle section routing by adding the following in the pattern file.

{mid_shielding $NET_NAME}

The shielding will have the same width as the corresponding signal routes. The shielding wires are logically assigned to the net $NET_NAME. It is the user's responsibility to keep the routing width less than the routing spacing so that that routing result is valid. In an 3D routing procedure, two layers of metal are used for signal routing. The metal layer beneath either layer is potentially used for the shielding. If the shielding metal cannot be derived, the tool will error out. If both signal routing layers are used, both shielding layers are used. In case that only one signal routing layer is occupied, due to missing nets, only the shielding layer between the two signal routing layers is used for shielding. The shielding routes are not placed above nor below the signal routes. Instead the shielding routes are aligned to the gaps between the signal routes. In this routing style, the signal

Feedback

routings are evenly spaced. Therefore, a shielding route can potential be shared by the signal routes on both sides.

If a channel contains less than 48 nets, the channel is called incomplete channel. An incomplete channel has the same number of bumps but a smaller number of nets. In case that the number of nets is very small, user can force the routing to occur in portions of the bump array regions using the keyword as boundary_stub_range follows.

{boundary_stub_range $range_low_upper $range_high_upper $range_low_lower $range_high_lower}

The values are in microns. The pair ($range_low_upper $range_high_upper) and ($range_low_lower $range_high_lower) define corridors in the upper and lower bump array regions, respectively where routing shapes are placed. Since the range is reduced, user must ensure the range is wide enough for all existing nets. When *boundary_stub_range* and *via_bump_abutment* are used together, the tool performs a more agressive routing style to ensure routeability than the case without *boundary_stub_range*. Vias can be abutted to any edge of bumps.

A stub is placed along the routing track, connecting to corresponding bump access via if the following is specified in the pattern file. The stubs are only on the high metal layer.

{bump_access_dir true}

The length of the stubs can be controlled by the following keyword bump_access_length. The default value is half routing width plus routing spacing.

{bump_access_length $DISTANCE}

The tool created two routing guide files for the subsequent RDL routing step. User can provide a prefix for the file names using the keyword route_guidance_file. The actual file names are created by combining the prefix with the corresponding metal layer names. The default prefix is hbm_p2p.txt.

{route_guidance_file $prefix}

User can use the keyword *stacked_via_dimension* to specify the configuration of any low-level vias placed beneath the interposer vias connected to bump. This keyword is used in the *exception* as follows.

{stacked_via_dimension $x_size $y_size}

All low-level vias share the same configuration. The default values are 2x2 when *via_bump_abutment* is false. When the keyword *via_bump_abutment* is true, the default values are 2x6 and 6x2 for vertical channels and horizontal channels, respectively.

Feedback

A keyword *middle_layer_switch* is introduced in the *exception* section in the *single_hbm* style. When it is used, a special routing pattern is used for the 3D channel routing. Specifically, two metal layers are used to route each net between corresponding bump-access vias. This routing style is only applicable when *via_bump_abutment* is false. The location of switching is in the middle of two bumps but not overlaps with any routing direction switch in the middle of the 3D channel.

During 3D routing, a detour is used to route around a via. The default detour spacing is *pitch-via_dimension/2-wire_width/2*. A keyword *detour_spacing* is added so that users can use it in the *exception* section to specify the exact value of detour spacing, namely the distance between the via and detour route. All routing detours share the same value. Users are responsible for the correctness of the value.

{detour_spacing $micron}

If the bump_region_compaction keyword is used in the pattern file, the tool tries to push all tracks inside of the bump array bounding box if possible The format of bump_region_compaction is shown below. The track_count is a positive integer that represents the maximal distance, which is the integer times the pitch of tracks.

{bump_region_compaction $track_count}

Preroutes are detected during 3D style routing. The detection area is the bump array bounding box enlarged by a margin. The default value of the margin is equal to half of bump dimension. User can change the margin using the following constraint in the pattern file. The value can be either positive or negative.

{blockage_region_extension $micron}

For *single_hbm* routing style, the two bumps of the same net should be at the same relative position in their corresponding bump arrays. In practice, bump assignment mismatch could occur. By default, the tool will error out after detecting bump assignment mismatch and ask users to change bump-net assignment. However, if the assignment cannot be changed, user can use keyword *stub_order_fix* in the *exception* section to force the tool to proceed. The tool will try to route with a high tolerant to wirelength mismatch. The tool will error out if no solution can be derived.

If the *vertical_routing* style is chosen, the keyword *vertical_route* can be used in the *exception* section to describe how the route mesh will be created. An example is given below. The first string following the keyword describes the metal layer. It is followed by the width and spacing of the routes to be created on that layer. The default width and spacing is the dimension of a single-size via beneath the layer. The last integer is optional. It specifies how many tracks to

Feedback

be created. If the track count is not provided, tracks will be added to cover the entire C4. The dimension of vias between routes are derived based on the track widths.

{vertical_route $layer_name $micron $micron $integer}

Description

This command places vias and routes for an interposer based on the netlist. It has four modes of operation depending on the style of interposer: default, single_hbm, vertical_routing and fpga. In the default mode, the command will only insert vias. In the single_hbm or vertical_routing or fpga mode, both vias and routes can be added. You can provide a pattern file which contains constraints for via and route insertion. The vias inserted by this command can be a single via (base via) or via array which connects a front side bump on the redistribution layer to a metal layer below. Any other vias that are stacked below the base via can also be created based on the specification in the pattern file. Any blockages and preroutes on metal layers related to new vias are considered so that no design-rule violations will occur. If any bumps or nets already have vias placed, no redundant vias will be added. After vias are added, you can use any router to complete the routing of the interposer.

The single_hbm mode is for a single column or row of a 3D channel. The tool creates vias and routes according to constraints in the pattern file. It also creates routing guidance files which are used by the subsequent RDL routing command to complete the routing. Many keywords for 3D channel route planning are used in the exception section of the pattern file. They are not applicable to other modes.

The vertical_routing mode is for the connection between a C4 bump and one or two micro bumps. Given a high-speed net with a C4 bump and one or two micro bumps, the tool will add vias and routing shapes to connect the C4 to the micro bump or micro bumps. Specifically, an RV via is added for each micro bump. The via is abutted to its micro bump. The top layer of the via is the layer of micro bumps. If there is a single micro bump, the default location of the via is along the top edge of the micro bump. The via is entirely inside the C4 bump. If the default location of via is not inside the C4 bump, the via will be placed along the bottom edge. If the via cannot be placed inside the C4 bump, the tool will error out. If there are two micro bumps, the default location is along the top or right edge, when the two micro bumps are aligned horizontally or vertically, respectively. A single route on the bottom layer of the via is added. If there is a single micro bump on the net, the route will be horizontal. Otherwise, the orientation of the route is the same as the alignment of the two micro bumps. On the layers between the top routing layer and layer of C4 bump pins, routing tracks are created to form connection mesh. Specifically, the routings on the layer just below the top routing layer are perpendicular to the routing on the top routing layer. The routing orientation then switches between horizontal and vertical in a round-robin manner in the following layers below until reaching the layer of the C4 pins.

Feedback

Examples

The following example places vias by using the default style.

```
prompt> create_interposer_routeplan
```

---

create_io_break_cells

Inserts I/O break cells into the floorplan.

Syntax

status *create_io_break_cells*

```
[-reference_cells lib_cell_name_list]
[-cells cell_name_list]
[-location start | end | both | offset | cell]
io_guide_list
```

Data Types

```
lib_cell_name_list  string
cell_name_list      string
offset              float
cell                string
io_guide_list       list
```

Arguments

`-reference_cells lib_cell_name_list`

Specifies the library cell names of the break cells. For each name in the list, the command inserts a new cell instance with the name __added_break_cell_index, where index is an integer. All new cells are placed consecutively with no gap in between.

`-cells cell_name_list`

Specifies the instance names of the break cells. All cell instances must already exist in the design. Only cell instance names are supported, collections are not supported.

Feedback

`-location start | end | both | offset | cell`

Specifies the location of the break cells to insert with respect to the corresponding I/O guide. You can specify only one guide when using this option.

When the keyword *start* or *end* is specified, the break cells are placed right before or after the I/O guide, respectively. You can also place the break cells at both ends of the I/O guide. If you specify *-location both*, only the *-reference_cells* option can be used.

The *offset* specifies the distance from the starting point of the I/O guide. When a *cell* is specified, the break cells are placed next to the specified cell, away from the guide starting point. If this cell is not placed in the guide, projection is used to determine the break cell location. That is, the cell is projected along its orientation direction toward the I/O guide. The crosspoint will be the location. Note that the cell must be in the correct orientation with respect to the I/O guide. Otherwise, no break cell are inserted.

io_guide_list

Specifies the list of I/O guides. This option is required.

Description

This command places one or more break cells at the intersection of two I/O guides or a specified location in one I/O guide. When one guide is given, the break cell location is determined by the *-location* option.

When two I/O guide names are given, the break cell location is derived from the two guides. If the two I/O guides are perpendicular, the location is the crossing point of the two I/O guides. If the two I/O guides are in parallel, they must have the same orientation. In addition, the extended lines of the two guides must overlap. There must be a gap between the two I/O guides. Otherwise, the command will error out. The break cell location always starts from the gap endpoint of the first I/O guide and extends toward the second I/O guide.

The orientations of the break cells are determined by the first I/O guide and the orientations of their reference cells. Specifically, if the first I/O guide has side set to bottom, the break cell orientations are the same as those of the reference cells. Namely, the break cell instances will be in R0 orientation. If the first guide is with different side values, the break cells will be rotated in the same way as that of IO guide with respect to a bottom guide. User can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, break cell orientations will be changed accordingly.

If the break cells are already in the netlist, use the *-cells* option. Otherwise, use the *-reference_cells* option. You can specify only one of the *-cells* and *-reference_cells* options.

Feedback

Examples

The following example inserts a break cell with the instance name "break_left" between the io guides io_guide_left and io_guide_top.

```
prompt> create_io_break_cells -cells break_left {io_guide_left
 io_guide_top}
```

The following example inserts a break cell with the reference name "LEFT_BREAK".

```
prompt> create_io_break_cells -reference_cells LEFT_BREAK {io_guide_left
 io_guide_top}
```

The following example inserts a break cell with the reference name "LEFT_BREAK" after a pad cell instance named "PAD".

```
prompt> create_io_break_cells -reference_cells LEFT_BREAK -location PAD
 io_guide_left
```

---

create_io_corner_cell

Inserts an I/O corner cell into the floorplan.

Syntax

status *create_io_corner_cell*

```
[-reference_cell lib_cell_name]
[-cell cell_name]
[-force block_pathname]
io_guide_list
```

Data Types

```
lib_cell_name  string
cell_name      string
io_guide_list  list
block_pathname string
```

Arguments

`-reference_cell lib_cell_name`

Specifies the library cell name of the corner cell. Only one name can be given. The command inserts a new cell instance with the name

Feedback

__added_corner_cell_*index*, where *index* is an integer. This option is mutually exclusive with the *-cell* option.

`-cell` *`cell_name`*

Specifies the instance name of the corner cell to be placed. Only one instance name can be given. This option is mutually exclusive with the *-reference_cell* option.

`io_guide_list`

Specifies the name of the two I/O guide names between which to place the corner cell. This option is required. The two guides must be perpendicular to each other.

`-force` *`block_pathname`*

Specifies the parent cell of the newly created corner cell. This option only takes effect if the newly created corner cell using -reference_cell overlaps with multiple hierarchical blocks. The bounding box of the new cell must overlap with the specified block path name.

Description

This command places a corner cell at the intersection of two I/O guides. The two I/O guides must be perpendicular. The location is the crossing point of the two I/O guides.

The orientation of the corner cell is determined by the first I/O guide and the orientation of its reference cell. Specifically, if the first guide is an IO guide with side set to bottom, the corner cell's orientation is the same as that of the reference cell. If first guide is with different side values, the corner cell be rotated in the same way as that of IO guide with respect to a bottom guide. User can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, corner cell orientation will be changed accordingly. For example, if users set the reference_orientation to R270, the corner cell will be in R0 orientation when the first guide has its side set to left.

If the corner cell is already in the netlist, use the *-cell* option. Otherwise, use the *-reference_cell* option. You can specify only one of the *-cell* and *-reference_cell* options.

Examples

The following example inserts a corner cell with the instance name "lt_corner" between the I/O guides io_guide_left and io_guide_top.

```
prompt> create_io_corner_cell -cell lt_corner {io_guide_left
 io_guide_top}
```

"SEE ALSO"

```
create_io_filler_cells(2)
place_io(2)
```

Feedback

create_io_filler_cells

Inserts I/O filler cells into the specified I/O guides.

Syntax

status *create_io_filler_cells*

```
[-io_guides io_guide_list]
[-reference_cells cell_list]
[-overlap_cells cell_list]
[-extension_bbox bounding_box]
[-prefix prefixString]
[-top]
[-block list_of_block_path_names]
[-force block_path_name]
[-auto_tie_to_pg]
```

Data Types

io_guide_list	collection
cell_list	collection
bounding_box	list
prefixString	string
list_of_block_path_names	string
block_path_name	string

Arguments

`-io_guides` *io_guide_list*

Specifies the names or collection of the target I/O guides. If this option is not used and the *-top* and *-block* options are not used, all I/O guides which are logically on top are selected.

`-reference_cells` *cell_list*

Specifies the lib cell names of the filler cells. These filler cells cannot overlap regular signal or power pad drivers. The reference cells must have difference widths. If there are two filler cells with the same width, only one is used.

`-overlap_cells` *cell_list*

Specifies the lib cell names of the filler cells that can overlap with regular signal or power pad drivers. The reference cells must have difference widths. If there are two filler cells with the same width, only one is used.

`-extension_bbox` *bounding_box*

Specifies the bounding box in which filler cells are placed. The filler cells can only be placed in the specified guides and the bounding box.

Feedback

`-prefix` *`prefixString`*

Specifies the added filler cell name prefix with *prefixString*. If this option is not specified, the command will use the default prefix string __added_filler_instance.

`-top`

Specifies the tool to select all I/O guides which are logically on top.

`-block` *`list_of_block_path_names`*

Specifies the tool to select I/O guides from the mentioned block path names.

`-force` *`block_path_name`*

Specifies the parent cell of the newly created filler cell. This option only takes effect if the newly created filler cell overlaps with multiple hierarchical blocks. The bounding box of the new cell must overlap with the specified block path name.

`-auto_tie_to_pg`

Specifies the tool to connect newly inserted filler cells to logical nets based on physical abutment.

Description

This command inserts filler cells into I/O guides. New filler cells are named __added_filler_instance_*index*, where *index* is a positive integer.

The orientation of a filler cell is determined by the orientation of its reference cell and the I/O guide which the filler cell is placed in. Specifically, if the filler cell is placed in an I/O guide with side set to bottom, its orientation is the same as that of the reference cell. If the filler cell is placed in I/O guides with different side values, the filler cell will be rotated in the same way as that of I/O guide with respect to a bottom guide. You can change the reference cell orientation by setting the reference_orientation attribute of the reference cell. Consequently, the filler cell orientations will be changed accordingly. For example, if you set the reference_orientation to MY, a filler cell placed in a bottom guide will be flipped on the y-axis.

In case, the user specifies the -auto_tie_to_pg option all the terminals of all pins of the newly inserted filler cells for a gap are collected as well as the terminals of the prexisting cells in that gap. The net connection is made for the newly inserted filler cells based on physical contact between the pins. A transitive connection relationship is applied to establish the net connection. The nets are only connected to the filler pins if no errors are reported during filler placement.

The *-block* and *-top* options are mutually exclusive with the *-io_guides* option.

Examples

The following example inserts filler cell "FILLER" into all I/O guides.

Feedback

```
prompt> create_io_filler_cells -reference_cells FILLER
```

---

create_io_guide

Creates an I/O guide in the current design.

Syntax

collection *create_io_guide*

```
[-name io_guide_name]
-line { {x y} length }
-side left | right | bottom | top
[-offset {start_gap end_gap} ]
[-pad_cells pad_cell_list]
[-min_pitch min_pitch]
```

Data Types

```
io_guide_name  string
x              float
y              float
length         float
start_gap      float
end_gap        float
pad_cell_list  list
min_pitch      float
```

Arguments

`-name io_guide_name`

Specifies the name of the I/O guide. If this option is not used, the I/O guide is named default_guide_*index*, where *index* is a positive integer.

Feedback

`-line { {x y} length }`

Creates an I/O guide along the horizontal or vertical line specified by a starting point {*x y*} and a length *length*. The orientation of the guide is defined by the *-side* option. Left and right lines must be vertical, and top and bottom lines must be horizontal. This is a required option. The line defines the outer edge of a target placement area for the pads associated with the I/O guide. The coordinates are relative to the chip origin.

`-side left | right | bottom | top`

Indicates the orientation of the I/O guide by specifying the outer edge. For instance, the I/O pads of a left guide are aligned on the right side of the guide line. All guides follow a clockwise orientation. For example, the starting point of a left guide is the bottom end of the line, and the starting point of a right guide is the top point of the line. This option is a required option.

`-offset {start_gap end_gap}`

Specifies the minimal distance (*start_gap*) between the first pad and the starting point of the guide and the minimal distance (*end_gap*) between the last pad and the ending point of the guide. By default, both offsets are zero.

`-pad_cells pad_cell_list`

Specifies a list of pad cells to be included in the I/O guide. The list can contain names, patterns, or collections. It is an error to include a pad cell whose reference module is not a pad type or a cell that has already been assigned to another I/O guide. This option is not required, you can create an empty I/O guide without specifying a pad cell list.

`-min_pitch min_pitch`

Specifies a minimum pitch between I/O drivers on the I/O guide. The distance between two consecutive I/O drivers can be zero, one or multiple times of the min pitch value. Min pitch will be honored during place_io.

There are some limitations. a. If there are conflicts between min pitch and signal I/O constraints or power I/O constraints, the tool will honor signal and power I/O constraints first. b. If there are multiple rings in design, only when there's no overlap between pads and I/O guides can the result be guaranteed.

Description

The *create_io_guide* command creates a line-based I/O pad constraints for I/O placement. The I/O placer uses the I/O guide to properly place the pads within the region. Unlike a move bound or group bound, I/O guides are ordered. Ordering is based on the constraints set by the *set_signal_io_constraints* command.

Note that it is possible to create an inconsistent I/O guide. There might be insufficient space within the specified line to fit the I/O pad cells with the required edge and spacing

Feedback

between pads. Secondly, there is nothing to enforce the position of the pad cells relative to the I/O guide. It is expected that the I/O placer will ensure that the I/O guide constraints are honored. If no *pad_cell_list* is provided as an argument, the command creates an empty I/O guide. You can add pad cells to the I/O guide with the *add_to_io_guide* command and remove pad cells from the I/O guide with the *remove_from_io_guide* command.

Examples

The following example creates an I/O guide named "io_guide1". The guide starts at location {100 100}, and extends north by 100 due to the *-side left* argument. The guide contains the pads "pad1" and "pad2", which align to the right of the I/O guide line.

```
prompt> create_io_guide -name "io_guide1" -line {{100 100} 100} \\
 -side left -pad_cells { pad1 pad2 }
```

---

create_io_ring

Creates an IO ring in the current design.

Syntax

collection *create_io_ring*

```
[-name ring_name]
[-inside outer_ring_name]
[-offset offset]
[-guides io_guide_list]
[-bbox bounding_box]
[-corner_height height]
[-pad_cell_list pad_list]
```

Feedback

Data Types

```
ring_name         string
outer_ring_name   string
offset            float
io_guide_list     list
bounding_box      bBox
height            float
pad_list          list
```

Arguments

`-name` *`ring_name`*

Specifies the string used as the ring name. If the command creates new IO guides, the ring name is used as the prefix for the IO guides of the ring. Specifically, the left, right, top, and bottom IO guides are named by adding .left, .top, right, and .bottom to the ring name, respectively. By default, the ring name is named _default_io_ring*index*, where index is a positive integer.

`-inside` *`outer_ring_name`*

Specifies the name of the (outer) IO ring that is used as the outer boundary for the new ring. When this option is used, the target bounding box is the inner perimeter of the specified outer ring, if the outer ring has a valid corner height. Otherwise, the target bounding box is the bounding box of the outer ring.

`-offset` *`offset`*

Indicates the required offset from the target boundary. Namely, the bounding box of the ring is computed as a rectangle inside of the target bounding box. The value specified with the *-offset* option is the distance between the target bounding box and the outer bounding box of the newly created ring. The default offset is 0.

`-guides` *`io_guide_list`*

Specifies a list of IO guides to be included in the IO ring. The list may contain names, patterns, or collections. This command does not perform any checking, you are responsible for the correctness of the IO guides and the guides should define a valid ring structure. If you specify an IO guide that is already assigned to another IO ring, the command issues an error message. This option cannot be used with any other options except for the *-name* option. When you use this option to create an IO ring, the corner height of the ring remains at 0.

`-bbox` *`bounding_box`*

Specifies the bounding box for the ring. If this option is not used and the target bounding box of the ring cannot be determined with other options such as *-inside*, the default bounding box is the inner bounding box of the smallest IO ring, or the die area if no IO ring exists.

Feedback

`-corner_height` *`height`*

Specifies the distance between the outer bounding box of the ring and inner bounding box of the ring. When you use the *-guides* option to create an IO ring, the corner height of the ring remains 0 until you set it to a different value. The default value is the height of the tallest pad cell instances assigned to the ring, or the height of the shortest pad cell instances in the design if no pad cell instance is assigned to the ring.

`-pad_cell_list` *`pad_list`*

Lists the pad cell instances to assign to IO guides inside the ring. The pads will be evenly assigned to the IO guides if the total width of pads in each IO guide is not more than the guide length. This list is not required and you can create a IO ring without specifying a pad cell list.

Description

This command creates or groups a related set of IO guides that are used for IO placement. Note that it is possible to create an inconsistent IO ring, especially for the inner rings of a concentric set. If the *-guides* option is not used, the command creates a default IO ring. The size of the IO ring is assigned using the following priority:

- The *-bbox* argument
- The inner bounding box of the outer ring, if given
- The boundary for the design
- The inner boundary of the smallest existing ring

The command also creates four IO guides: _default_io_ring1.left, _default_io_ring1.bottom, _default_io_ring1.right, and _default_io_ring1.top. You can add additional IO guides to the IO ring with the *add_to_io_ring* command. You can also remove IO guides from the IO ring with the *remove_from_io_ring* command. You can also assign pad cell instances to the ring during the creation of the ring or add pad instances to each guide in the ring at a later time.

Examples

The following example creates two IO rings and populates them with pad cells:

```
prompt> create_io_ring -name io_ring1
 prompt> add_to_io_guide io_ring1.bottom {ioPad_1 ioPad_2 ioPad_3
 ioPad_4}
 prompt> add_to_io_guide io_ring1.left {ioPad_5 ioPad_6 ioPad_7 ioPad_8}
 prompt> add_to_io_guide io_ring1.top {ioPad_12 ioPad_11 ioPad_10
 ioPad_9}
 prompt> add_to_io_guide io_ring1.right {ioPad_16 ioPad_15 ioPad_14
 ioPad_13}
 prompt> create_io_ring -name io_ring2 -inside io_ring1
```

Feedback

```
prompt> add_to_io_guide io_ring2.bottom {ioPad_17 ioPad_18 ioPad_19}
prompt> add_to_io_guide io_ring2.left {ioPad_20 ioPad_21 ioPad_22}
prompt> add_to_io_guide io_ring2.top {ioPad_25 ioPad_24 ioPad_23}
prompt> add_to_io_guide io_ring2.right {ioPad_28 ioPad_27 ioPad_26}
```

The following example creates four IO guides (io_guide1, io_guide2, io_guide3, and io_guide4), then places the guides into an IO ring named "io_ring1".

```
prompt> create_io_guide -name io_guide1 -side left -line {{0 0} 2000}
prompt> create_io_guide -name io_guide2 -side top -line {{0 2000} 2000}
prompt> create_io_guide -name io_guide3 -side right -line {{2000 2000}
 2000}
prompt> create_io_guide -name io_guide4 -side bottom -line {{2000 0}
 2000}
prompt> create_io_ring -name "io_ring1" -guides { io_guide1 io_guide2
 io_guide3 io_guide4 }
```

---

create_keepout_margin

Creates design and cell keepout margins.

Syntax

```
collection create_keepout_margin
   [-type hard | soft | hard_macro | routing_blockage | clock |
   seal_ring | assembly_die]
   [-outer margin_spec]
```

Feedback

```
[-inner margin_spec]
[-layers layers]
[-tracks_per_macro_pin number_of_tracks]
[-min_padding_per_macro padding_size]
[-max_padding_per_macro padding_size]
[design_and_cell_list]
```

Data Types

```
margin_spec           list
layers                list
number_of_tracks      float
padding_size          float
design_and_cell_list  list
```

Arguments

`-type hard | soft | hard_macro | routing_blockage | clock | seal_ring | assembly_die | filler_allowed`

Specifies the type of the keepout margin to create. Valid values are

- *hard* (the default)

  A hard keepout margin prevents objects from being placed in the keepout margin area throughout the entire flow. However, it would not prevent hard macros being placed in the keepout margin area.

- *soft*

  A soft keepout margin prevents the coarse placer from placing objects in the keepout margin area, but optimization and legalization can place objects within the keepout margin. Also, it would not prevent hard macros being placed in the keepout margin area.

- *hard_macro*

  A hard macro keepout margin prevents hard macros from being placed in the keepout margin area throughout the entire flow.

- *routing_blockage*

  A routing blockage keepout margin prevents PG routes from being placed in the keepout margin area.

- *clock*

  A clock keepout margin prevents clocks from being placed in the keepout margin area.

- *seal_ring*

Feedback

A seal_ring keepout margin around the block to prevent any shapes from being placed in the keepout margin area. Only outer keepout can be set for this type. The margin must be pointing outward (positive), and can only be placed on a block.

- *assembly_die*

  An assembly_die keepout margin around the block or seal_ring keepout to prevents any shapes from being placed in the keepout margin area. Only outer keepout can be set. The margin must be pointing outward (positive), and can only be placed on a block. An assembly die keepout is relative to the seal_ring keepout if a seal_ring keepout is set, otherwise it is relative to the block.

- *filler_allowed*

  A filler_allowed keepout margin is a hard keepout and prevents objects from being placed in the keepout margin area throughout the entire flow. However, it would not prevent filler cells or hard macros being placed in the keepout margin area.

`-outer` *`margin_spec`*

Specifies the padding margin to maintain outside of the design or cell boundary. This setting is used for physical designs and cells.

Use the following syntax to specify the margins:

`{`*`left bottom right top`*`}`

The margin parameters must be zero or positive and all four parameters are required. The directions are relative to the core area. The units are microns.

`-inner` *`margin_spec`*

Specifies the padding margin to maintain inside the design boundary. This option is not valid for leaf cells.

Use the following syntax to specify the margins:

`{`*`left bottom right top`*`}`

The margin parameters must be zero or positive and all four parameters are required. The directions are relative to the core area. The units are microns.

`-layers` *`layers`*

Specifies the layers for the routing_blockage type keepout. This option must by specified with, and can only be used with the *-type routing_blockage* keepout. Providing an empty layer list causes an error. Specify the layers by using the layer names from the technology file.

Feedback

`-tracks_per_macro_pin` *`number_of_tracks`*

Specifies the number of tracks per macro pin. This option setting is used to calculate the keepout margin based on wire tracks. When you specify *-tracks_per_macro_pin*, the outer keepout margin is calculated by multiplying the number of tracks by the number of pins. For example, if you set *number_of_tracks* to 0.5, and the macro contains 100 pins on the side, the keepout margin for that side is 50 tracks.

```
100 pins * 0.5 tracks/pin = 50 tracks
```

The *-tracks_per_macro_pin* is mutually exclusive with the *-inner* and *-outer* options.

`-min_padding_per_macro` *`padding_size`*

Specifies the minimum padding distance per macro. This value is used to calculate the keepout margin based on pin count, and is valid only with the *-tracks_per_macro_pin* option. By default, the minimum padding is the minimum grid size, which is 0.

`-max_padding_per_macro` *`padding_size`*

Specifies the maximum padding size per macro. This value is used to calculate the keepout margin based on pin count, and is valid only with the *-tracks_per_macro_pin* option. By default, there is no maximum padding value.

`design_and_cell_list`

Specifies the list of physical designs and cells for which to create keepout margins.

Description

The *create_keepout_margin* command creates keepout margins for the specified physical designs and cells.

The outer and inner keepout margins can be set explicitly with the *-outer* and *-inner* options. Outer keepouts are allowed only on leaf cells and physical designs. Inner keepouts are allowed only on physical designs and are not supported on leaf cells.

Outer keepout margins can be created for macro cells based on the pin count by using the *-tracks_per_macro_pin* option. The minimum and maximum margins can be specified using the *-min_padding_per_macro* and *-max_padding_per_macro* options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Examples

The following example creates the soft outer keepout margin on a leaf cell.

Feedback

```
prompt> create_keepout_margin -type soft \\
   -outer {10 10 10 10}  [get_cells MY_LEAF_CELL]
```

The following example creates the hard outer and inner keepout margins on a design.

```
prompt> create_keepout_margin -type hard \\
   -outer {10 10 10 10} -inner {5 5 5 5} [get_designs MY_DESIGN]
```

The following example creates the hard outer and inner keepout margins on a physical design.

```
prompt> create_keepout_margin -type hard \\
   -outer {10 10 10 10} -inner {5 5 5 5} [get_cells MY_BLOCK]
```

The following example creates the hard outer keepout margin based on the pin count of the macro.

```
prompt> create_keepout_margin -tracks_per_macro_pin .6 \\
   -min_padding_per_macro .1 -max_padding_per_macro 0.2 [get_cells
 MY_MACRO]
```

The following example creates the routing_blockage keepout margin for the PG router on a macro cell for the specified layers.

```
prompt> create_keepout_margin type routing_blockage \\
   -outer {10 10 10 10} -layers {M1 M3 M5} [get_cells MY_MACRO]
```

---

create_layer

Creates a layer in the given tech object.

Syntax

collection *create_layer*

```
[-tech tech_object ]
-name layer_name
-number layer_number
[-purpose purpose_object ]
[-layer_type layer_type ]
[-mask_name mask_name ]
```

Feedback

```
[-before reference_layer ]
[-after reference_layer ]
```

Data Types

```
layer_name            string
layer_number          int
layer_type            string
mask_name             string
reference_layer       string or collection
```

Arguments

`-tech`

Layer will be created in this tech object. If not specified then tech object of current library will be used.

`-name layer_name`

Specifies the name of the layer to be created.

`-number layer_number`

Specifies the number of the layer to be created.

`-purpose`

Layer will be created using this purpose object. If not specified then the default purpose used for layer creation is "drawing". This option is mutually exclusive with -before and -after.

`-layer_type layer_type`

Specifies the type of the layer to be created. Valid values are: *diffusion*, *implant*, *interconnect*, *local_interconnect*, *local_via_cut*, *mim_interconnect*, *mim_via_cut*, *n_implant*, *nwell*, *p_implant*, *place_and_route*, *pwell*, *sadp_trim*, *unknown*, and *via_cut*. Default layer type is unknown.

`-mask_name mask_name`

Specifies the mask_name of the layer to be created.

`-before reference_layer`

Specifies the mask_order of the layer to be created relative to the given reference layer. The reference layer should be an ordered layer with valid mask_order before which the created layer will be inserted. Please note that this option would increment the mask_order of all higher order layers including the given reference layer to create space in the mask_order sequence for insertion of the created new layer. If unspecified, the mask_order of the created layer is -1 (unordered). This option is mutually exclusive with -after and -purpose.

Feedback

`-after` *`reference_layer`*

Specifies the mask_order of the layer to be created relative to the given reference layer. The reference layer should be an ordered layer with valid mask_order after which the created layer will be inserted. Please note that this option would increment the mask_order of all higher order layers excluding the given reference layer to create space in the mask_order sequence for insertion of the created new layer. If unspecified, the mask_order of the created layer is -1 (unordered). This option is mutually exclusive with -before and -purpose.

Description

create_layer command creates a layer in the given technology. The layer creation requires a name and a number for the new layer. If a purpose is specified, then the new layer uses the given purpose, otherwise the new layer uses the default purpose "drawing".

If the command is successful, it returns the newly-created layer as a single-element collection. If the command fails, it returns TCL_ERROR with appropriate error message. If there is a syntax error, it returns a TCL_ERROR.

Examples

The following example creates a layer in the technology of the current design.

```
prompt> create_layer -tech [get_techs [current_lib]] -name test_layer
 -number 100 -purpose signal
{test_layer:signal}
```

The following example creates the same layer without -tech option.

```
prompt> create_layer -name test_layer -number 100 -purpose signal
{test_layer:signal}
```

The following example creates the same layer with mask_name and mask_order after layer M1.

```
prompt> create_layer -name test_layer -mask_name test_layer -after M1
 -number 100
{test_layer}
```

---

create_left_right_filler_cells

Inserts left or right filler cells for specific center cells.

Feedback

Syntax

status *create_left_right_filler_cells*

```
-lib_cells center_left_right_pair_list
[-prefix prefix]
[-boundaries polyrect_list]
[-voltage_areas va_list]
[-rules rule_list]
[-follow_stdcell_orientation]
```

Data Types

center_left_right_pair_list	list
prefix	string
polyrect_list	list
va_list	list
rule_list	list

Arguments

`-lib_cells` *center_left_right_pair_list*

Specifies the list of center cell list, left filler cell list and right filler cell list pair. The format should be {{{center_cell_list1} {left_filler_list1} {right_filler_list1}} {{center_cell_list2} {left_filler_list2} {right_filler_list2}}...}. By default, the tool adds the left right filler cells in the order that you specify. We recommend to specify them from the largest to smallest. The center cell list, left filler list and right filler list allow wildcard "*" specification. If wildcard is used for left filler list and right filler list, the order will be the same with that you get from *get_lib_cells*. The center cell list can't be empty. Either the left or right filler list can be empty. For example, {{center_cell_list} {left_filler_list} {}} or {{center_cell_list} {} {right_filler_list}}. But left and right filler lists can't be empty simultaneously. Besides, a lib cell can't be repeated in two or more center cell lists. If so, only the last specification will be used.

`-prefix` *prefix*

Adds the specified prefix to the instance names of left right filler cells inserted by this command. You can later use the prefix to identify the filler cell instances.

`-boundaries` *polyrect_list*

Specifies the rectangular or rectilinear polygon regions (in microns) where left right filler cells are to be inserted. A rectangle is specified as a list of two points, {{*llx lly*} {*urx ury*}}, which represent the lower-left and upper-right corners of the rectangle.

By default, left right filler cells are inserted in the entire chip.

Feedback

`-voltage_areas` *va_list*

Specifies the voltage areas in which to insert left right filler cells.

By default, the tool inserts left right filler cells in all voltage areas.

`-rules` *rule_list*

Specifies the special rules to follow during left right filler cell insertion.

You can specify one or more of the following keywords:

- *no_1x*

  Indicates this is no-1x design. Prevents tool from placing left right filler cells such that it would leave a 1x gap.

`-follow_stdcell_orientation`

Specifies the left and right filler cells to follow the center cell's orientation. If the center cell's orientation is R180 or MY, its left and right side will be swapped. Besides, its left right filler cells' orientation will be MY on R0 rows and R180 on MX rows. If the center cell's orientation is R0 or MX, its left right filler cells' orientation will be R0 on R0 rows and MX on MX rows.

By default, the tool will place the left right filler cells with the allowable orientation of the corresponding rows.

Description

This command inserts left or right filler cells for the specified center cells. The height of center cells must be multiple integer of the height of the left or right filler cells. There will be no gaps between the left or right filler cells and its corresponding center cells. Intercell spacing rules will be ignored.

After the left or right filler cells insertion, you may use check_legality to verify filler placement legality.

Examples

The following example inserts left and right filler cells for center cells whose reference library named mylib/Center_1 and it also inserts left filler cells for center cells whose reference library named mylib/Center_2. All the left and right filler cells will only be inserted within the specified region {{0 0} {500 500}}. If the sizes of the left filler cells are such that LeftFiller_4X > LeftFiller_2X > LeftFiller_1X, this ordering minimizes the number of left filler cells added by using the larger filler cells first. And it was the same case for the right filler cells.

```
prompt> create_left_right_filler_cells \\
   -lib_cells { { {mylib/Center_1} \\
                  {mylib/LeftFiller_4X mylib/LeftFiller_2X} \\
                  {mylib/RightFiller_2X mylib/RightFiller_1X} } \\
```

Feedback

```
                { {mylib/Center_2} \\
                  {mylib/LeftFiller_2X mylib/LeftFiller_1X} \\
                  {} } \\
              } \\
   -boundaries {{0 0} {500 500}}
```

- check_legality

---

create_length_limit

Creates an analog constraint group with wire_length_limit intent in the current design.

Syntax

collection *create_length_limit*

```
[constraint_group_name]
-for objects
[-min_value float]
[-exclude objects]
[-driver objects]
[-force]
```

Data Types

constraint_group_name	string
objects	collection
float	float

Arguments

constraint_group_name

Specifies the name of the constraint group. If not specified then a system generated name is assigned.

-for *objects*

Specifies the objects - can be nets, pins, ports, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

-min_value *float*

Specifies the minimum value that needs to be achieved by each constituent object in the constraint group. The default is zero.

Feedback

`-exclude` *objects*

Specifies the objects that need to be excluded from the analog constraint group. The objects can be pins or ports, and can be specified as strings (object names) or collections. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in *-for* option but want to exclude a few pins / ports connecting to that net.

`-driver` *objects*

Specifies the object to be treated as the driver for the analog constraint group. The object can be a pin or port, and can be specified as a string (object name) or collection. This option is useful when user gives a net which is connecting physically (across logical hierarchies) to multiple pins / ports in *-for* option but want to control the length of each driver to receiver connection.

`-force`

Specifies force deletion of existing constraint group by the same name as specified and re-creation of new constraint group. The default is false and the command exits with error if same name is encountered.

Description

The *create_length_limit* command creates a constraint group for a collection of nets, pins, ports, bundles, and topology_edges with wire_length_limit intent. Each constituent object must honor the minimum value specified for its wire length. Constraint applicable on pin/port check the net which is connecting pin/port to driver pin/port. The constraint is used by Custom Router.

Examples

The following example creates a constraint group named 'abc' for nets and bundles matching the pattern 'pr*' such that none of the constituent objects have wire length lesser than 10. The 'pr*' nets are routed with Custom Router.

```
prompt> create_length_limit abc -for pr* -min_value 10
{abc}
```

- get_constraint_groups
- remove_constraint_groups
- report_constraint_groups

---

create_lib

Creates a design library.

Feedback

Syntax

collection *create_lib*

```
[-technology tech_path | -use_technology_lib tech_lib_name]
[-use_parasitic_tech_lib para_tech_lib_name]
[-scale_factor scale_factor]
[-ref_libs ref_libs]
[-convert_sites site_name_pairs_list]
[-base_lib base_library_path]
[-dont_set_current]
library_name
```

Data Types

```
tech_path              string
tech_lib_name          string
para_tech_lib_name     string
scale_factor           integer
ref_libs               list
site_name_pairs_list   list
base_library_path      string
library_name           string
```

Arguments

`-technology tech_path`

Specifies the technology file for this library.

`-use_technology_lib tech_lib_name`

Specifies the reference library to use as a dedicated technology library.

The library must contain a technology section and must be one of the libraries specified with the *-ref_libs* option.

This option is mutually exclusive with the *-technology* option, and it must be used with the *-ref_libs* option.

`-use_parasitic_tech_lib para_tech_lib_name`

Specifies one library on the reference library list as a dedicated parasitic logic library.

You must use this option with the *-ref_libs* option.

`-scale_factor scale_factor`

Specifies the length precision for this library. The length precision for the library and all of its reference libraries must be identical. The value is specified in terms of units per micron. By default, a length precision of 10000 is used, which implies one internal unit is equal to one Angstrom or 0.1 nm

Feedback

Choose a *scale_factor* value that results in a whole number of database units per minimum grid spacing. For example, if your minimum grid spacing is 1 nm, the default scale_factor of 10000dbu per micron could be used. But if your minimum grid spacing is 0.25 nm, a scale factor of, for example, 4000, must be used otherwise rounding errors might result.

`-ref_libs` *`ref_libs`*

Specifies the reference libraries for this library.

In addition to pre built cell libraries, this option accepts physical source data such as physical libraries (which contain frame views of the cells), LEF files, and Milkyway libraries. The tool automatically builds cell libraries based on the physical source data.

You can specify the reference libraries and physical source data using absolute or relative paths. If you specify the libraries with a relative path or with no path, the tool uses the search path defined with the *search_path* variable to locate the libraries.

`-convert_sites` *`site_name_pairs_list`*

Specifies the mapping for the site names in the technology file in the following format:

{*`tech_file_site_name new_site_name`*}

This option must be used with the *-technology* option.

`-base_lib` *`base_library_path`*

Creates a sparse library based on the specified library. The base library must be a design lib and cannot be a lib-cell library. No other options can be specified when the *-base_lib* option is used. For example, the sparse library must use the same technology file and ref_libs as the base library.

`-dont_set_current`

An optional argument to create the lib without setting it as the current lib.

`library_name`

Specifies the name of the new library. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after he last '/' becomes the name of the library. It is an error if a library, file, or directory with the same name already exists on disk.

The name can be a simple path, a path relative to the current working directory, or an absolute path. The name cannot contain spaces or the colon (":") character, which is used to delimit the library and design name.

Feedback

The *library_name* is optional when *-base_lib* option is used. If unspecified, the name of the created local sparse library matches the name of the base library specified using the *-base_lib*.

Description

The *create_lib* command creates a new design library. The library can contain technology information specified with the *-technology* option. If there are sites defined in the technology file (and one is being used), you can use the *-convert_sites* option to map the sites from one name to another. This same option is used with the *read_def* command to ensure that the site names match among all the input data.

You can directly specify the library's reference library path list with the *-ref_libs* option. Alternatively, if you specify physical source data with the *-ref_libs* option, the tool creates the cell libraries and sets them as reference libraries. The supported physical source data includes physical libraries, which contain the frame views of the cells, LEF files, and Milkyway libraries. The logic libraries are determined from the *link_library* variable. The created cell libraries are put in the directory specified by the *lib.configuration.local_output_dir* application option. You can use the *lib.configuration.default_flow_setup* application option to point to a Tcl script with customized settings for the cell library creation. See the man pages of these application variables and options for detailed information about how to use them.

When the *-base_lib* option is used the *create_lib* command creates a new sparse library based upon an existing design library on disk. The sparse library uses the same technology file and ref_libs as the base library. Initially, a sparse library does not have any locally stored blocks. It copies the base library's catalog and ref_lib list into memory as its own and also remembers the full path of the base library for reference.

The library is then opened and made the current library.

If the command is successful, it returns the newly-created library as a single-element collection. If the command fails, it returns an empty string. If there is a syntax error, it returns a TCL_ERROR.

Examples

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000
Information: Loading technology file
 '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{r4000}
prompt> current_lib
{r4000}
```

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file and has a scale factor of 4000.

Feedback

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000 -scale_factor
 4000
Information: Loading technology file
 '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{r4000}
prompt> current_lib
{r4000}
prompt> get_attribute [current_lib] scale_factor
4000
```

The following example creates a library named top_lib in the ./lib_dir directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf lib_dir/top_lib
Information: Loading technology file
 '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
{top_lib}
```

The following example creates a library named design_lib in the /home/user directory that uses the my_tech.tf technology file.

```
prompt> create_lib -technology my_tech.tf /home/user/design_lib
Information: Loading technology file 'my_tech.tf' (FILE-007)
{design_lib}
```

The following example creates a sparse library named top_sparse_lib based on the design library top_lib in the /home/user directory.

```
prompt> create_lib -base_lib /home/user/top_lib top_sparse_lib
Information: Creating Sparse View library 'top_sparse_lib' with base
library '/home/user/top_lib'. (NDM-103)
{top_sparse_lib}
```

The following example creates a library named design_lib and automatically creates cell libraries for it. The cell libraries are created based on the logic library files specified in the *link_library* variable and the physical library specified with the *-ref_libs* option.

```
prompt> set_app_var link_library \\
   "* 1_pvt1.db 1_pvt2.db 2_pvt1.db 2_pvt2.db"
prompt> create_lib -technology my_tech.tf /home/user/design_lib \\
   -ref_libs frame_only.ndm
 ... run lm_shell to build reference libraries.
 ..........................................................
Information: Successfully built 3 reference libraries: 1.ndm 2.ndm
EXPLORE_physical_only.ndm
{design_lib}
```

create_libset

Create a libset in Libra from reference libraries

Syntax

status *create_libsets*

```
-name libset_name_string
-libs library_object_list
```

Data Types

```
libset_name_string string
library_object_list list-of-library-objects
```

Arguments

`-name`

The name of the libset that will be created.

`-libs`

The libset will be created from this set of reference libraries.

Description

Creates a named libset from a collection of reference libraries. The *libset* is a named group of reference libraries. The libset has a unique name string, and many Libra commands take *-libset* which allows you to specify that name. This is easier than keeping track of the many library files that are analyzed together, and defining one also allows

Feedback

Libra to do some initial checking for consistency and data validity across all the libraries that you will analyze.

So, *create_libset* is actually the beginning of most user flows in Libra. Multiple libsets can exist simultaneously, and individual library dbs can appear in multiple libsets. Use *report_libset* to see more information about each libset you create, and *delete_libset* to delete any libsets that you wish to delete.

Note that when you have created a libset, if you then close/remove one of the libraries within it, the libset will still exist, but will not contain that library.

Here is an example of using the command:

```
create_libset -name myLibset -libs $MY_LIBS
Information: Created libset myLibset from: abcd1.db (LRA-1000)
1
```

This creates a libset named 'myLibset' from the given libraries. You can then use the string name "myLibset" as an input argument to other Libra commands that require it.

See Also

- report_libset

---

create_logic_net

Creates a logic net

Syntax

status *create_logic_net*

```
        net_name
```

Data Types

net_name string

Arguments

net_name

Specifies the name of the net to create.

Description

The create_logic_net command creates a logic net in the current scope.

Feedback

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

See Also

- create_net

---

create_logic_port

Creates a logic port

Syntax

string *create_logic_port*

```
port_name
[-direction in | out | inout]
```

Data Types

```
port_name   string
```

Arguments

port_name

Specifies the name of the port to create.

`-direction in | out | inout`

Specifies the direction of the port. The default is *in*.

Description

The create_logic_port command creates a logic port in the current scope. Logic ports should be created before corresponding isolation and level-shifting strategies are applied so any isolation or level-shifting strategy defined for a power domain may apply to logic ports created on the boundary of that power domain.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

See Also

- create_port

---

create_macro_array

Arranges macros into an array.

Feedback

Syntax

collection *create_macro_array*

```
-num_rows rows
-num_cols columns
[-horizontal_channel_height list_of_numbers]
[-vertical_channel_width list_of_numbers]
[-align align_mode]
[-orientation list_of_orientations]
[-flip_alternate_rows]
[-flip_alternate_cols]
[-create_group true | false]
[-name edit_group_name]
[-fill_pattern by_row | by_col | by_row_snake_pattern |
 by_col_snake_pattern]
macros
```

Data Types

rows	integer
columns	integer
list_of_numbers	list
align_mode	string
list_of_orientations	list
edit_group_name	string
macros	collection

Arguments

`-num_rows` *rows*

Specifies the number of rows in the array.

`-num_cols` *columns*

Specifies the number of columns in the array.

`-horizontal_channel_height` *list_of_numbers*

Specifies the height of each horizontal channel. The height for each macro is set based on its position in the list. If there are fewer elements in the list than there are channels, the remaining channel heights are set to the first element of the list. In particular, if only one number is specified, all heights are set to that number. The default for all heights is 0. Note that heights are calculated from macro edges; keepout margins are not considered.

`-vertical_channel_width` *list_of_numbers*

Specifies the width of each vertical channel. The width for each macro is set based on its position in the list. If there are fewer elements in the list than there are channels, the remaining channel widths are set to the first element of the list. In particular, if only one number is specified, all widths are set to that number.

Feedback

The default is for all widths is 0. Note that the widths are calculated from macro edges; keepout margins are not considered.

`-align` *`align_mode`*

Specifies the edge or corner of each macro to which to align for non-homogeneous macro arrays. The valid values are *center*, *top*, *bottom*, *right*, *left*, *top_left*, *bottom_left*, *top_right*, and *bottom_right*.

The default is *center*.

`-orientation` *`list_of_orientations`*

Specifies the orientation for each macro in the array, based on its position in the list. If there are fewer elements in the list than there are macros, the remaining macro orientations are set to the first element of the list. In particular, if only one orientation is specified, all macro orientations are set to that value. The default is for all orientations to be unchanged from the current value.

Legal orientation values are: N, FN, S, FS, E, FE, W, and FW

- N - specifies an R0 orientation
- FN - specifies an MY orientation
- S - specifies an R180 orientation
- FS - specifies an MX orientation
- E - specifies an R270 orientation
- FE - specifies an MYR90 orientation
- W - specifies an R90 orientation
- FW - specifies an MXR90 orientation

`-flip_alternate_rows`

Flip macros in every other row. By default, macros are not flipped.

`-flip_alternate_cols`

Flip macros in every other column. By default, macros are not flipped.

`-create_group true | false`

Specifies whether to create an edit group for the macro array. The default is true.

`-name` *`edit_group_name`*

Specifies the name of edit group to create. This option is valid only if *-create_group true* is specified. If *-name* is not specified and -create_group is

Feedback

true, a unique default name, MACRO_ARRAY_#, is used to name the macro. If *-name* is specified and the specified name already exists in another edit group, the command issues an error message.

`-fill_pattern by_row | by_col | by_row_snake_pattern | by_col_snake_pattern`

Specifies how macros are placed in the array. by_row places macros starting from the first column; new rows are started from the first column. by_row_snake_pattern creates the array row-by-row, but with each row starting where the previous row ended, thus creating a snake pattern.

by_col and by_col_snake_pattern are similar, but place macros column-by-column rather than row-by-row The default fill pattern is by_row.

macros

Specifies a list of macros to place in the array.

Description

This command arranges a list of macros in an array and optionally creates an edit group for the array. If an edit group is created, the command returns it; otherwise a collection equal to the list_of_objects argument is returned.

Examples

The following example creates an array from the selected macros.

```
prompt> create_macro_array -num_rows 2 -num_cols 2 [get_selection] -name
 my_edit_group
```

The following example creates an array from the selected macros and specifies their channels widths, and heights. The orientation for each macro in the array is N.

```
prompt> create_macro_array -num_rows 4 \\
   -num_cols 3 [get_selection] -orientation { N } \\
   -horizontal_channel_height 10 \\
   -vertical_channel_width { 10 20 }
```

The following example creates an array from the selected macros and specifies their orientations, channels widths, and heights.

```
prompt> create_macro_array -num_rows 4 \\
   -num_cols 3 [get_selection] -orientation { N S N S } \\
   -horizontal_channel_height 10 \\
   -vertical_channel_width { 10 20 }
```

The following example returns all macro arrays (edit groups that begin with "MACRO_ARRAY_") and deletes them.

Feedback

```
prompt> set macro_arrays [get_edit_groups -filter name=~MACRO_ARRAY_*]
{MACRO_ARRAY_0}
prompt> remove_edit_groups $macro_arrays
1
```

See Also

- create_edit_group
- get_edit_groups
- remove_edit_groups

---

create_macro_groups

Creates macro groups.

Syntax

```
collection_of_macro_group create_macro_groups
-method auto | by_hierarchy | by_connectivity | by_pattern |
 by_index_pattern | by_macros
[-names group_names]
[-pattern pattern_string]
[-index_pattern index_pattern_string]
[-macros list_of_macros]
[-preview]
```

Data Types

group_names	string or list
pattern_string	Regular expression
index_pattern_string	Index pattern expression
list_of_macros	collection of macros

Arguments

`-method auto | by_hierarchy | by_connectivity | by_pattern | by_index_pattern | by_macros`

Specifies the method to use to create the macro group. There are five modes to create macro groups: auto, by_hierarchy, by_connectivity, by_pattern, by_index_pattern, and by_macros.

auto is the default method. This method is the same as default grouping method of *create_placement -floorplan* command. It groups macros based on combinations of hierarchy, connectivity, and coarse placement result.

by_hierarchy is the same grouping by hierarchy method of *create_placement -floorplan* command. It groups macros purely based on hierarchy information.

Feedback

by_connectivity is the same grouping by connectivity of *create_placement -floorplan* command. It groups macros based on connectivity between macros and sequential cells.

by_pattern method groups macros based on name pattern. The *-pattern* option must be specified to use this method. Pattern is a regular expression string. Macros which match the pattern and belong to same placeable area will be grouped together. For example, assume the following four macros belong to same block:

```
HIER1/MEM_1_1
HIER1/MEM_1_2
HIER1/MEM_1_3
HIER1/MEM_1_4
```

In this case, use the following command to create a macro group which contains these four macros. If one macro belongs to another macro group before this command, the command removes it from its previous macro group and assign it to the new macro group.

```
prompt> create_macro_groups -method by_pattern \\
    -pattern HIER1/MEM_1*
```

by_index_pattern method group macros based on index pattern. The *-index_pattern* option must be specified to use this method. Index pattern is comprised of fixed text and index. Index has two types, fixed and auto. Fixed index is represent as ?, fixed index is represented as *. Fixed index is used to group macros of same placeable area together. For example, assume the following four macros belong to the same placeable area:

```
HIER/MEM_1_1
HIER/MEM_1_2
HIER/MEM_2_1
HIER/MEM_2_2
```

The following command can be used to group the macros:

```
prompt> create_macro_groups -method by_index_pattern \\
  -index_pattern HIER/MEM_?_*
```

The command specifies the index pattern as HIER/MEM_?_*. The question mark (?) represents a fixed index and the star character (*) represents an auto index. The command will first find all macros which match the pattern, i.e, macros with name HIER_MEM_number1_number2. Since the index pattern indicates the first number is fixed, and second is auto, the command will group macros with same first number together and create the following two groups:

```
HIER/MEM_1_1
HIER/MEM_1_2
```

Feedback

```
and

HIER/MEM_2_1
HIER/MEM_2_2
```

The following command uses a different index_pattern.

```
prompt> create_macro_groups -method by_index_pattern \\
    -index_pattern HIER/MEM_*_?
```

The index pattern indicates the first number is auto, and the second number is fixed. The command will create the following two groups:

```
HIER/MEM_1_1
HIER/MEM_2_1

and

HIER/MEM_1_2
HIER/MEM_2_2
```

by_macros method creates macro group based on given macros. The *-macros* option must be specified to use this method. The command will create a macro group which contains macros in the list.

`-names` *`group_names`*

Specifies the names for each macro group as a list of strings. The *create_macro_groups* command can create multiple groups. Each item is a group name. If the number of names specified in this option is more than macro groups created by the command, additional names will be discarded. If the number of names specified in this option is less than macro groups created by the command, the command will create default names for additional macro groups. If any name is already used by other macro group, the command will issue a warning message and pick a default name.

`-pattern` *`pattern_string`*

Specifies the regular expression to use when matching macro names. This option must be used together with the *-method by_pattern* option.

`-index_pattern` *`index_pattern_string`*

Specifies the index pattern to use when matching macro names. This option must be used together with the *-method by_index_pattern* option.

`-macros` *`list_of_macros`*

Specifies the list of macros to group together. This option must be used together with the *-method by_macros* option.

Feedback

`-preview`

Return a list of collections that contain the macro groups to be created. The actual macro groups are not created. Use this option to experiment with different options and patterns to and view the resulting macro groups without creating the groups.

Description

This command creates macro groups and is used in the Macro Placement Assistant flow. Use the Macro Placement Assistant flow to group and pack macros based on pattern matching and other criteria. This is different from command *create_placement -floorplan*, where the grouping and packing of macros are done automatically. A typical macro placement assistant flow is as follows:

1. Place macros. Macros can be placed automatically by the *create_placement -floorplan* command or by hand.
2. Use the *create_macro_groups* command to create macro groups. User can use different methods to create macro groups. Macros of same macro groups should be placed together.
3. Create the macro group contours with the *set_macro_group_shape* command.
4. Pack macros using the *pack_macro_group* command.

You can undo the change at any step to experiment with different macro placements. Macro groups are treated as a subclass of movebounds. A macro group contains a group of macros and a contour. All macros of one macro group must belong to the same macro group. A placeable area can be a movebound, a voltage area, or a block. When a macro group is first created, its contour will be placed outside of block area. Use *set_macro_group_shape* command to modify the contour.

Examples

The following command creates macro groups with the auto method

```
prompt> create_macro_groups -method auto
```

The following command creates a macro group for the specified macros

```
prompt> create_macro_groups -method by_macros \\
    -macros [get_cells {M1 M2 M3 M4}]
```

The following command prints macro groups which will be created by method by_pattern.

```
prompt> create_macro_groups -method by_pattern \\
    -pattern  I_ORCA_TOP/I_CONTEXT_MEM/I_CONTEXT_RAM_* \\
    -preview
```

---

create_macro_relative_location_placement

Performs macro placement based on the relative location placement constraints.

Syntax

status *create_macro_relative_location_placement*

```
[-hierarchical]
```

Arguments

`-hierarchical`

Performs macro relative location placement in the top-level design and in the child blocks. By default, the command performs macro relative location placement in the current block.

Description

This command performs macro relative location placement based on the constraints for current block. If the *-hierarchical* option is specified, the command places the macros in the current block and the macros in child blocks.

Examples

The following example performs relative location placement on current block.

Feedback

```
prompt> create_macro_relative_location_placement
1
```

The following example performs relative location placement on the top-level block and in the child blocks.

```
prompt> create_macro_relative_location_placement -hierarchical
1
```

See Also

- create_placement
- remove_macro_relative_location

---

create_manufacturing_shape

Creates a manufacturing shape object in the current design.

Syntax

collection *create_manufacturing_shape*

```
-type seal_ring | assembly_die | stitching_zone | custom
[-name shape_name]
[-label abel]
[-boundary boundary_spec]
[-offsets distance_spec]
```

Data Types

shape_name	string
boundary_spec	list
distance_spec	list

Arguments

`-type seal_ring | assembly_die | stitching_zone | custom`

Specifies the type of manufacturing shape to create. This is a required option.

`-name` *shape_name*

Optionally specifies the name of the manufacturing shape to be created. With *-type seal_ring*, this is a required option. For other types, this option is not allowed, and the name is auto generated by the tool.

Feedback

`-label` *label*

Optionally specifies a custom string label for the manufacturing shape to be created. Labels aren't unique, meaning that 2 manufacturing shapes can share the same label. With *-type custom*, this is a required option. For other types, this option is not allowed

`-boundary` *boundary_spec*

Specifies the list of points which represent the boundary corners of the manufacturing shape, or a pair of points representing it in the form of bounding box. You can use the following methods to specify the boundary:

- Specify a rectangular boundary by using the following syntax to specify the lower-left and upper-right corners of the rectangle:

  `{{llx lly} {urx ury}}`

- Specify a rectilinear boundary by using the following syntax to specify the boundary of the polygon:

  `{{x1 y1} {x2 y2} ... {xn yn}}`

  This option cannot be specified along with *-offsets* option.

`-offsets` *distance_spec*

Specifies the distance values which are the offsets of the shape with respect to the die boundary. These must be specified in the order of left, top, right and bottom offset values by using the following syntax: {*dleft dtop dright dbottom*}. This option is only supported if the die boundary is rectangular. This option cannot be specified along with *-boundary* option.

Note that using this option does not mean that the offset values are always preserved. In other words, if the block boundary is modified, the manufacturing shape is not updated.

Description

This command creates a new manufacturing shape of the specified type in the current block and returns the newly created object, if successful. The shape dimensions can be specified via either the *-boundary* or the *-offsets* options, exactly one of which must be specified.

Examples

The following command creates an assembly die shape.

```
prompt> create_manufacturing_shape -type assembly_die -boundary {{0 0}
 {1000 1000}}
```

Feedback

The following command creates a seal ring shape with name SL1 and equal offsets around the die boundary.

```
prompt> create_manufacturing_shape -type seal_ring -name SL1 -offsets {10
 10 10 10}
```

The following command creates a custom shape with label CUS1 with a rectangle boundary.

```
prompt> create_manufacturing_shape -type custom -label CUS1 -boundary {{0
 0} {10 10}}
```

See Also

- get_manufacturing_shapes
- remove_manufacturing_shapes
- report_manufacturing_shapes

---

create_marker_layers

Populates a set of shape objects in the marker layers in the given design.

Syntax

collection *create_marker_layers*

```
[-design design]
[-cells cells]
[-references references]
[-horizontal_extension hextension]
[-vertical_extension vextension]
[-horizontal_offset_from_cell hoffset]
[-vertical_offset_from_cell voffset]
[-exclude { { {llx lly} {urx ury} } |
            { {x y} {x y} {x y} {x y} ... } } |
            geometric_objects]
```

Data Types

```
design              collection
cells               collection
references          string
hextension          string
vextension          string
hoffset             string
voffset             string
llx                  float
lly                  float
urx                  float
```

Feedback

```
ury                 float
x                   float
y                   float
geometric_objects   collection
```

Arguments

`-design` *design*

Specifies the top design for finding objects. If this is not specified, objects will be found in the current design.

`-cells` *cells*

Specifies the collection of cells which are to be excluded for generating the shapes in the marker layers.

`-references` *references*

Specifies the names of the IPS which are to be excluded for generating the shapes in the marker layers.

`-horizontal_extension` *hextension*

Specifies the horizontal extension for marker layers where the tracks are vertical. The input is a list of layername and extension pairs. The extension value can be positive or negative.

`-vertical_extension` *vextension*

Specifies the vertical extension for marker layers where the tracks are horizontal. The input is a list of layername and extension pairs. The extension value can be positive or negative.

`-horizontal_offset_from_cell` *hoffset*

Specifies the horizontal offset from excluded cells or references for generating the shapes of the marker layers.The input is a list of layername and offset pairs. The offset value can be positive or negative.

`-vertical_offset_from_cell` *voffset*

Specifies the vertical offset from excluded cells or references for generating the shapes of the marker layers.The input is a list of layername and offset pairs. The offset value can be positive or negative.

`-exclude { {{`*llx lly*`} {`*urx ury*`}} | {{`*x y*`} {`*x y*`} {`*x y*`} {`*x y*`}...} } | geometric_objects`

Specifies the objects to be excluded from the marker layers. The object list can be a heterogeneous collection of poly_rect, geo_mask, shape, layer, and other physical objects.

Feedback

Description

This command creates a collection of new rectangles and polygons on the marker layers and returns a collection that contains the new shape.

Examples

The following example creates shapes on the marker layers.

```
prompt> create_marker_layers -references {IP1 IP3} -cells u1 \\
   -horizontal_extension {{{M2_P48 10} {M3_P48 20}}}
```

The following example creates shapes on the marker layers where offset from cells and references are specified.

```
prompt> create_marker_layers -references {IP1 IP3} -cells u1 \\
   -horizontal_extension {{{M2_P48 10} {M3_P48 20}}}
   -horizontal_offset_from_cell {{{M2_P48 6} {M3_P48 8}}}
```

See Also

- get_shapes
- remove_shapes

---

create_mask_constraint_routing_blockages

Creates routing blockages around the terminals and boundaries in the current top-level design, or around the block pins and inside the block instance boundaries on the layers that have mask constraints defined.

Syntax

status *create_mask_constraint_routing_blockages*

```
[-cells cells]
[-create_placement_blockages]
[-self]
```

Data Types

```
cells     collection
```

Arguments

`-cells cells`

Specifies a list of block instances in which to create the mask constraint routing blockages. If this option is omitted, the command creates mask constraint routing blockages inside each of the block instances within the current top-level design.

Feedback

The command places mask constraint routing blockages inside the specified block instances (or all of the block instances if omitted). The blockages surround the block pins on the layers where mask constraints are defined.

`-create_placement_blockages`

Creates placement blockages in addition to routing blockages. The shapes and locations of the placement blockages are the union of the mask constraint routing blockages.

`-self`

Specifies that the mask constraint routing blockages are created at top-level design. The mask constraint routing blockages are created in the top-level design and surround the top-level terminals on layers where mask constraints are defined. This option is mutually exclusive with the *-cells* option.

When this option is omitted, mask constraints routing blockages are created inside the block instances within the current top-level design.

Description

This command creates mask constraint routing blockages, and optionally creates placement blockages. If the technology file for the current top-level design defines mask constraint rules on one or more layers, this command creates routing blockages. If the *-self* option is specified, routing blockages are created around the terminals and boundaries of the top-level design. If the *-self* option is not specified, the command creates routing blockages around the block pins and inside the block instances specified by the *-cells* option. If both *-self* and *-cells* options are omitted, the command creates routing blockages inside all of block instances. Blockages are created on the layers that have the mask constraint rules defined. The *set_editability* can enable/disable this command for blocks or levels of physical hierarchy. This command has no effect on the blocks that are disabled by *set_editability*.

Routing blockages prevent the router from accessing those terminals or the block pins on the same layers within a certain distance of the boundaries and avoid creating mask constraint violations.

The routing blockages created by this command use the naming style __DPT_ROUTING_BLOCKAGE_x__, where x is a nonnegative integer. If the design already contains a routing blockage with the same naming style, the tool deletes the blockage automatically.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

Feedback

Examples

The following example creates double-patterning routing blockages for the current top-level design.

```
prompt> create_mask_constraint_routing_blockages
```

See Also

- create_routing_blockage
- set_editability

---

create_matching_type

Creates a matching type in the current block.

Syntax

collection *create_matching_type*

```
-name matching_type_name
[-uniquify count]
[object_list]
```

Data Types

```
matching_type_name string
count              int
object_list        list
```

Arguments

`-name matching_type_name`

Specifies the name of the matching type. The name must be unique among all matching types in the block.

`-uniquify count`

Specifies how bump cells are assigned to pad pins within the same matching type. This is optional. If specified, the valid value range is [-4, 8]. If the value is > 0, the value indicates the number of pad pins that can be assigned to a single bump cell, and no two bump cells can be assigned to the same pad pin. If the value is < 0, the absolute value indicates the number of bump cells that must be assigned to each pad pin, and no two pad pins can be associated to the same bump cell. If the value = 0, only 1 bump cell is assigned to all pad pins.

Feedback

object_list

Specifies a list of cells, pins, and terminals to add to the matching type. The list can contain names, patterns, or collections. This list is optional. You can create an empty matching type without specifying any object list. It is an error to add an object which is already in another matching type. Each object can exist in at most one matching type in the block.

Description

This command defines a matching type constraint. A matching type specifies which bump cells are to be connected to which pad pins through its list of objects. It also optionally specifies how this is done through its uniquify number. If the matching type contains only bumps or no bumps, no bump assignment will be performed on its list of objects.

When I/O placement is performed, objects can be connected only to other objects with the same matching type. The matching type exists only in the block in which it was created, but its containing objects can span into subblocks. This means that the current block's matching types can apply to objects in subblocks when performing I/O placement from the current block, but matching types created in other blocks are not visible from the current block.

A pin is a RDL pin if it contains at least a single terminal with class attribute equal to bump. When a pad is in a matching type, all its RDL pins are in the matching type. When a RDL pin with multiple terminals with class attribute equal to bump is included in a matching type, only a single terminal will be selected for bump assignment and RDL routing. To force the tool to connect all, users need to create a matching type with all terminals explicitly described. Bumps and the uniquify number must also be set accordingly.

Examples

The following example creates a matching type named "myMatchingType1" with cell "bump" and pin "padCell/padio".

```
prompt> create_matching_type -name "myMatchingType1" -uniquify 0 \\
   [list [get_cells bump] [get_pins padCell/padio]
```

Feedback

create_material

Creates a material object in the current library.

Syntax

collection *create_material*

```
-name material_name
-type type
[-thermal_conductivity thermal_conductivity]
-density density
-specific_heat_capacity specific_heat_capacity
[-prandtl_number prandtl_number]
[-nusselt_number nusselt_number]
[-cte cte]
[-youngs_modulus youngs_modulus]
[-shear_modulus shear_modulus]
[-thermal_conductivity_anisotropic thermal_conductivity_anisotropic]
```

Data Types

material_name	string
type	string
thermal_conductivity	double
density	double
specific_heat_capacity	double
prandtl_number	double
nusselt_number	double
cte	double
youngs_modulus	double
shear_modulus	double
thermal_conductivity_anisotropic	list

Arguments

`-name material_name`

Specifies the name of material to be created. This is a mandatory option.

`-type type`

Specifies the type of the material. Valid values are *conductor* and *dielectric*. This is a mandatory option.

`-thermal_conductivity thermal_conductivity`

Specifies the thermal conductivity of the material, popularly denoted by k, i.e. its ability to conduct heat. It is a double value in the units W/m-oC, i.e. W/m-K. Note that this physical property can vary with temperature, the value specified is the thermal conductivity at 25 oC(degree Celsius), i.e. room temperature. At least one of the *thermal_conductivity* or *thermal_conductivity_anisotropic* options must be specified.

Feedback

`-density` *density*

Specifies the density of the material. It is a double value in the units g/cm^3. Note that this physical property can vary with temperature, the value specified is the density at 25 oC, i.e. room temperature. This is a mandatory option.

`-specific_heat_capacity` *specific_heat_capacity*

Specifies the specific heat capacity of the material, popularly denoted by cp. It is a double value in the units J/g-oC, i.e. J/g-K. Note that this physical property can vary with temperature, the value specified is the specific heat capacity at 25 oC, i.e. room temperature. This is a mandatory option.

`-prandtl_number` *prandtl_number*

Specifies the Prandtl number of the material, popularly denoted by Pr. It is a double value without any units. Note that this physical property can vary with temperature, the value specified is at 25 oC, i.e. room temperature. This is an optional option.

`-nusselt_number` *nusselt_number*

Specifies the Nusselt number of the material, popularly denoted by Nu. It is a double value without any units. This is an optional option.

`-cte` *cte*

Specifies the Coefficient of Thermal expansion of the material, popularly denoted by CTE. It is a double value with the units 1e-6/oC. Note that this physical property can vary with temperature, the value specified is the value at 25 oC, i.e. room temperature. This is an optional option.

`-youngs_modulus` *youngs_modulus*

Specifies the Young’s Modulus of the material, popularly denoted by E. It is a double value with the units GPa. Note that this physical property can vary with temperature, the value specified is the value at 25 oC, i.e. room temperature. This is an optional option.

`-shear_modulus` *shear_modulus*

Specifies the Shear Modulus value of the material, popularly denoted by G. It is a double value with the units GPa, i.e. 1e06 N/m2. Note that this physical property can vary with temperature, the value specified is the value at 25 oC, i.e. room temperature. This is an optional option.

`-thermal_conductivity_anisotropic` *thermal_conductivity_anisotropic*

Specifies the anisotropic thermal conductivity of the material. It is a list of 3 double values in the units W/m-oC, i.e. W/m-K. Note that this physical property can vary with temperature, the value specified is the anisotropic thermal conductivity at 25 oC(degree Celsius), i.e. room temperature. At least one of

Feedback

the *thermal_conductivity* or *thermal_conductivity_anisotropic* options must be specified.

Description

This command creates a material object in the current library and returns the newly created object, if successful.

The material can be used to model any object used in the multi-die assembly environment for which thermal analysis can be done.

This command requires a current library, but does not require a current design to be present.

Examples

The following command creates a material 'mat_1' with type as conductor.

```
prompt> create_material -name mat_1 -type conductor -thermal_conductivity
 401 \\
    -density 8900 -specific_heat_capacity 900
```

The following command creates a material 'mat_2' with type as conductor. option.

```
prompt> create_material -name mat_2 -type conductor -thermal_conductivity
 420 \\
    -density 10800 -specific_heat_capacity 235 -prandtl_number 373 \\
    -nusselt_number 8.81 -cte 18.5 -youngs_modulus 69 -shear_modulus 24
 \\
    -thermal_conductivity_anisotropic {400 500 300}
```

The following command creates a material 'mat_3' with type as conductor.

```
prompt> create_material -name mat_3 -type conductor -thermal_conductivity
 {250} \\
    -thermal_conductivity_anisotropic {100 200.8 300.5} -density 8.2
 -specific_heat_capacity 900.5
```

---

create_metal_area

Creates a metal area.

Feedback

Syntax

collection *create_metal_area*

```
-boundary boundary
-net net
-layer layer_name
[-top]
[-bottom]
[-above metal_area]
[-below metal_area]
```

Data Types

```
boundary          string
net               collection
layer_name        collection
metal_area        collection
metal_area        collection
```

Arguments

`-boundary { {llx lly} {urx ury} } | {{x y} {x y} {x y} {x y}...}`

Specifies the boundary of the metal area. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}). A polygon is specified by its points as {*x y*} {*x y*} {*x y*} {*x y*} and so on. This is a required option.

`-net net`

Specifies the net with which to associate the metal area. Specify the netby using a collection or by specifying the net name. This is a required option.

`-layer layer_name`

Specifies the layer with which to associate the metal area. Specify the layer by using a collection or by specifying the layer names from the technology file. This is a required option.

`-top`

Places the metal area above all other existing metal areas. A metal area on top has higher stacking order.

`-bottom`

Places the metal area below all other existing metal areas. A metal area on bottom has higher stacking order.

`-above metal_area`

Place the metal area above the given metal area.

Feedback

`-below` *metal_area*

Place the metal area below the given metal area shape.

Description

The *create_metal_area* command creates a metal areas for a particular net of the layer name. The metal area is created on a stacking order based on the user input parameters like top, bottom, above or below. By default, the metal area is created on top and has highest stacking order.

Examples

The following example creates a metal area for a layer of a net:

```
prompt> create_metal_area -boundary {{0 0} {1000 1000}} -net test_mode
 -layer METAL2
{MA_0}
```

See Also

- get_metal_areas
- remove_metal_areas
- report_metal_areas

---

create_metal_area_hole

Creates a metal area hole.

Syntax

collection *create_metal_area_hole*

```
-boundary boundary
-metal_area metal_area
```

Data Types

```
boundary          string
metal_area        collection
```

Arguments

`-boundary { {llx lly} {urx ury} } | {{x y} {x y} {x y} {x y}...}`

Specifies the boundary of the metal area hole. The boundary can be a rectangle or a polygon. A rectangle is specified by its lower-left and upper-right coordinates as {*llx lly*} {*urx ury*}). A polygon is specified by its points as {*x y*} {*x y*} {*x y*} {*x y*} and so on. This is a required option.

Feedback

`-metal_area` *metal_area*

Specifies the metal area with which to associate the metal area hole. Specify the metal area by using a collection or by specifying the metal area name. This is a required option.

Description

The *create_metal_area_hole* command creates a metal area hole for a particular metal area.

Examples

The following example creates a metal area hole for the specified metal area:

```
prompt> create_metal_area_hole -boundary {{150 150} {170 170}}
 -metal_area MA_0
{MAH_0}
```

See Also

- get_metal_area_holes

---

create_mim_capacitor_array

Places Metal-Insulator-Metal (MIM) capacitor cells in the design in an array style. When inserting MIM capacitor cells, the command ignores placement blockages, macros, standard cells and PG network routes.

Syntax

status *create_mim_capacitor_array*

```
-lib_cell lib_cell
-x_increment distance
-y_increment distance
[-prefix prefix]
[-orientation R0|R90|R180|R270|MX|MY|MXR90|MYR90]
[-boundary polygon]
```

Data Types

lib_cell	string
distance	float
prefix	string
polygon	list

Feedback

Arguments

`-lib_cell` *lib_cell*

Specifies the MIM capacitor library cell explicitly. This option is required.

`-x_increment` *distance*

Specifies the horizontal distance between the centers of two cells.

`-y_increment` *distance*

Specifies the vertical distance between centers of two cells.

`-prefix` *prefix*

Specifies the prefix added to the MIM capacitor cell name.

`-orientation R0|R90|R180|R270|MX|MY|MXR90|MYR90`

Specifies the orientation of the MIM capacitor cells placed by this command. The orientation can be R0, R90, R180, R270, MX, MY, MXR90, MYR90. If not specified, the default orientation is R0.

`-boundary` *polygon*

Specifies the area in which to place MIM capacitor cells.

Description

This command places the cells into the design in an array style.

Examples

The following example places MIM capacitor cells.

```
prompt> create_mim_capacitor_array -lib_cell my_lib/mim_ref_cell \\
   -x_increment 20 -y_increment 20
```

See Also

- create_cell

---

create_mim_layer_capacitors

Creates a Metal-Insulator-Metal (MIM) capacitor in the design. When creating a MIM capacitor, it helps voltage stabilization and therefore, noise and transient IR drop.

Syntax

status *create_mim_layer_capacitors*

`-mim_layer_net` *mim_layer_net*
`-rv_layer` *rv_layer*

Feedback

```
[-areas areas]
[-via_def_names via_def_names]
[-exclude_areas areas]
[-max_width width]
[-max_height height]
[-verbose]
[-exclude_overlap_net_type net_type_names]
[-all_slot all_slot]
```

Data Types

mim_layer_net	list
rv_layer	string
areas	list
via_def_names	list
number_of_vias	integer
width	float
height	float
verbose	boolean
exclude_overlap_net_type	list
all_slot	*list*

Arguments

`-mim_layer_net` *mim_layer_net*

Specifies the mim layer, cutout layer and net name list. This option is required. Please write in order from the top to the bottom.

`-rv_layer` *rv_layer*

Specifies the name of via layer. This option is required.

`-areas` *areas*

Specifies areas that MIM Cap can be allocated. It is mutually exclusive to -exclude_areas option.

`-via_def_names` *via_def_names*

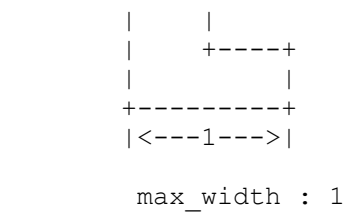
Specifies the via definition names. Please write in order from the top to the bottom. Only available on 2 plate MIM Cap creation.

`-exclude_areas` *areas*

Specifies the areas that MIM Cap can not be allocated, excluding the areas part. It is mutually exclusive to -areas option.

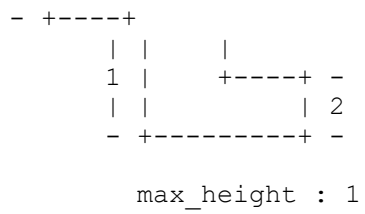
`-max_width` *width*

Specifies the maximum width of slice. If there is command option, the width in command option is used. If not, the width in technology file is used.



`-max_height` *`height`*

Specifies the maximum height of slice. If there is command option, the height in command option is used. If not, maximum height is used as the max_height.



`-verbose`

Gives the information where and why it failed to create MIM Capacitors at each stage.

`-exclude_overlap_net_type` *`net_type_names`*

If clock or signal nets cross under or over MIM CAP, RC can be affected by MIM shapes. To prevent this from happening, when setting the option, tool will not create MIM shapes overlap with *net_type_names*.

Available net_type: analog_ground, analog_power, analog_signal, clock, deep_nwell, deep_pwell, ground, nwell, power, pwell, reset, scan, signal, tie_high, tie_low

`-all_slot`

In 3 plate MIM Cap creation, vias and all 3 plates are not connected. Only available on 3 plate MIM Cap creation.

Description

This command creates MIM capacitors into the design. In 3-plate case, there are 3 metal plates that top and bottom plate connect power(VDD) and middle plate connects ground(VSS), and vice versa. In 2-plate case, there are 2 metal plates that top plate connects power(VDD) and bottom plate connects ground(VSS), and vice versa.

Examples

The following example creates 2-plate MIM capacitors.

Feedback

```
prompt> create_mim_layer_capacitors -mim_layer_net {{Layer1 Ground}
 {Layer2 Power}} \\
   -rv_layer via_name \\
   -via_def_names {top_plate_via_name middle_plate_via_name} \\
   -exclude_areas {{{10 25} {33 25} { 33 33} {10 33} {10 25}}} \\
   -max_width 176 \\
   -max_height 175 \\
   -verbose \\
   -exclude_overlap_net_type {clock signal}
```

The following example creates 3-plate MIM capacitors.

```
prompt> create_mim_layer_capacitors -mim_layer_net {{Layer1 Cutout1
 Ground} {Layer2 Cutout2 Power} {Layer3 Cutout3 Ground}} \\
   -rv_layer via_name \\
   -areas {{{10.7 22.7} {27.1 32.6}}} \\
   -max_width 176 \\
   -max_height 175 \\
   -verbose \\
   -exclude_overlap_net_type {clock signal} \\
   -all_slot {Layer Cutout}
```

See Also

- create_mim_capacitor_array
- report_mim_capacitor

---

create_mismatch_config

Creates a new config.

Syntax

status *create_mismatch_config*

```
config_name
[-ref_config name]
```

Data Types

```
config_name     string
name            string
```

Arguments

config_name

Specifies the config name to be created.

Feedback

`-ref_config` *name*

Specifies the reference config to be used for creating new config. If no ref_config is passed, then the most restrictive config will be used, i.e. *default*. Pre-defined configs available are: auto_fix and default. One config among pre-defined configs or user defined configs can be used as a reference config.

Description

This command creates a new config. It uses the ref_config to create the new config if passed any. If no ref_config is passed, most restictive config which is *default* is used to create the new config. Pre-defined configs are: default and auto_fix. auto_fix being permissive and default being restrictive.

If the new named config already exists, or reference config does not exists, proper messaging is given. The *report_mismatch_configs* can be used to list all the available configs in a session. So, once *create_mismatch_config* succeeds for a config, *report_mismatch_configs* will report this config too.

The *set_current_mismatch_config* command can be used to set the newly created config as current config of a session.

Examples

The following example creates new config:

```
prompt> create_mismatch_config user-def
1
prompt> create_mismatch_config user-def
Error: Mismatch config 'user-def' already exists. (DMM-016)
0
```

The following example creates a new config based on a ref config:

```
prompt> create_mismatch_config user-def1 -ref_config auto_fix
1
```

The following example creates a new config using a user defined config:

```
prompt> create_mismatch_config user-def
1
prompt> create_mismatch_config user-def1 -ref_config user-def
1
prompt> create_mismatch_config user-def3 -ref_config user-def10
Error: Mismatch config 'user-def10' do not exists. (DMM-015)
0
```

---

create_ml_db

Creates a database and opens this database after creation.

Syntax

string *create_ml_db*

```
-datastore cassandra | serverless
[-server server_path]
database_name
```

Data Types

```
server_path      string
database_name      string
```

Arguments

`-datastore cassandra | serverless`

Specify the datastore.

`-server server_path`

An optional argument that defines server location for "cassandra" datastore. By default it will use the path from the CERBERUS_HOME environment variable. No effect to "serverless" datastore.

database_name

The name of the database to create/open. For "serverless" datastore, the "/" in the name indicates the delimiter of directory path.

Description

This command creates a database and opens/connects to it. If the database has already existed, just opens and connects to it.

For "serverless" datastore, it will create the directories seperated by the "/" delimiter, if they are not existed.

This command returns the name of the created/opened database if successful, or "0" if not, with a TCL error raised.

Feedback

Examples

The following example creates a database "demo_ml_db" in the cassandra datastore.

```
prompt> create_ml_db -datastore cassandra demo_ml_db

The following example creates a database "ml_db" in the directory
 "./demo" as
serverless datastore.

prompt> create_ml_db -datastore serverless ./demo/ml_db
```

See Also

---

create_ml_db_record

Creates a new record in an open database.

Syntax

status *create_ml_db_record*

```
-hier
record_name
```

Data Types

```
record_name      string
```

Arguments

`-hier`

Specifies to create a hierarchical record. A hierarchical record is a record in the hierarchy of a database.

record_name

Specifies the name of the record to be created under the current working hierarchical record. If the *record_name* starts with slash “/”, it traverses from the root of the database. Otherwise, the name is relative to the current working hierarchical record.

Feedback

Description

This command creates a new record under the current working hierarchical record in an open database.

Examples

The following example creates a hierarchical record "block1" under the hierarchical record "project1", which is under the root hierarchical record in the database.

```
prompt> create_ml_db_record -hier /project1/block1

The following example creates a hierarchical record "block1" under the
 current working
hierarchical record.

prompt> create_ml_db_record -hier block
```

See Also

- current_ml_db_record
- set_working_ml_db_record
- get_working_ml_db_record
- create_ml_db
- open_ml_db

---

create_mlmp_data

The command creates ML data for ML macro placement from an optimized design. It retrieves congestion and timing data from current design, extracts features of macro placement, and then outputs the corresponding ML data in a CSV file.

Syntax

status *create_mlmp_data*

```
[-output output_file_name]
```

Data Types

```
output_file_name   string
```

Arguments

`-output`

Specify the output file of the created ML data. The file name must be with the suffix csv. The option is required.

Feedback

Description

The command creates ML data for ML macro placement from an optimized design. It retrieves congestion and timing data from current design, extracts features of macro placement, and then outputs the corresponding ML data in a CSV file. In addition to the specified CSV file, a hidden file with suffix .signature is also created. Both the created CSV file and signature files are needed for ML macro placement.

Examples

The following example creates ML data file hm.csv and signature file .hm.csv.signature.

```
prompt> create_mlmp_data -output hm.csv
```

See Also

- place_macro_ml
- set_host_options

---

create_mode

Creates a mode in the current design.

Syntax

string *create_mode*

```
        mode_name
```

Data Types

mode_name string

Arguments

mode_name

Specifies the name of the mode being created.

Description

Creates a mode in the current design. Modes are used to contain a set of constraints environment for the design. Unique modes are often used for different combinations of operating modes and power schemes. Modes are used together with corners, which contain operating condition and parasitics parameters. Timing analysis is actually done for various mode/corner combinations, as configured by the *set_scenario_status* command.

Feedback

Constraints are contained in the current mode. When the design is linked, a single mode named "default" is automatically created and set to be the current mode. If the *create_mode* command is used, the current_mode is set to the newly-created mode. You can set the current mode to a different mode with the *current_mode* command.

To create a collection of modes matching a pattern and optionally matching filter criteria, use the *get_modes* command. To get a collection of all modes in the design, use the *all_modes* command.

To undo *create_mode*, use the *remove_modes* command.

Examples

The following example creates a mode named "Mission5" and sets it to be the current mode.

```
prompt> create_mode Mission5
```

See Also

- all_modes
- current_mode
- get_modes
- remove_modes
- create_corner
- set_scenario_status

---

create_module

Creates one or more modules within a design.

Syntax

collection *create_module*

```
[-design design]
modules
```

Data Types

```
design  collection
modules list
```

Feedback

Arguments

`-design` *design*

Specifies the design to create the modules in. If no design is specified, the modules are created in the *current_design*.

modules

Specifies the names of the modules to be created in the design. Each module name must be unique.

Description

This command creates new modules in the current design. A module is a definition of logical hierarchy within a physical design block. The newly created modules are empty, they have no ports or cells. Instances of these modules may then be created with the *create_cell* command.

Unused modules may be deleted with the *remove_modules* command.

Examples

The following example creates a module named FOO.

```
prompt> create_module FOO
```

The following example creates modules named *MOD1*, *MOD2*, and *MOD3*.

```
prompt> create_module {MOD1 MOD2 MOD3}
```

See Also

- create_cell
- current_design
- remove_modules

---

create_multibit

Creates a multibit cell from a list of single-bit cells.

Syntax

status *create_multibit*

```
object_list
[-name multibit_cell_name]
[-lib_cell lib_cell_name]
[-sort ascending | descending | none ]
```

Feedback

Data Types

object_list	list
multibit_cell_name	string
lib_cell_name	string

Arguments

object_list

Specifies a list of single-bit registers or latches or mv cells in the current design from which a multibit cell is created. The specified cells are removed from the netlist and replaced by the multibit cell. For the list of unmapped single-bit cells, the order of the nets in the multibit cell is alphanumerically descending or determined by the -sort option. For the list of mapped single-bit cells, the order in which the cells are listed determines the order in which the nets are connected to the multibit cell. The list of cells cannot have a mix of unmapped and mapped single-bit cells.

-name *multibit_cell_name*

Specifies the name of the new multibit cell. If this option is omitted, the command derives a name by concatenating the names of *object_list*.

-lib_cell *lib_cell_name*

Specifies the name of the library reference cell used for the new cell. The bit-width of the specified library cell must be at least as large as the total bit-width of the cells specified in the *object_list*. You can specify only one library cell name. Specifying the library name along with the cell name (for example, my_lib/my_cell) is mandatory. The option *-lib_cell* is not supported if the *object_list* is a list of unmapped single-bit cells.

-sort *ascending* | *descending* | *none*

Sorts the single-bit cells alphanumerically in the ascending order, descending order, or maintains the existing order, when the order is none. If the option is omitted, the single-bit cell names are sorted alphanumerically in the descending order.

Description

The *create_multibit* command creates a new multibit cell from a list of registers or latches or mv cells in the current design. All the single-bit cells in *object_list* are replaced by one multibit cell.

When the list contains unmapped single-bit cells, the *create_multibit* command first creates a bus and the *compile_fusion* command performs mapping to a multibit cell. The order in which the single-bit cells are added to the bus is determined by the *-sort* option. The command issues an error if, (i) one or more single-bit cells already belong to a bus in

Feedback

the design, (ii) the single-bit cells belong to different hierarchies, and (iii) the single-bit cells are not functionally equivalent.

When the list contains mapped single-bit cells, the command verifies that the cells in the *object_list* exist in the design and have valid locations, and do not have a "dont_touch" or "fixed" attribute. The order of the specified cells determines the pin connection order of the new multibit cell. For example, a net connected to the third specified cell in the *object_list* is connected to the third bit of the multibit cell inserted by the command. If the multibit library cell has a larger bit-width than the total bit-width of the specified cells, the pins of the unused bits of the cell are left dangling. If a pin of a specified cell does not have a corresponding pin in the multibit library cell, the tool disconnects the pin and issues a warning message. To automatically generate a script containing *create_multibit* commands, use the *identify_multibit* command.

Examples

The following example creates a multibit register cell from 4 single-bit registers:

```
prompt> create_multibit -name group0_0 \\
  {reg_1 reg_2 reg_3 reg_4} -lib_cell REG_4_BIT
```

The following example creates a bus from 4 single-bit unmapped registers:

```
prompt>  create_multibit -name reg_bus_inst \\
    {reg_7 reg_10 reg_9 reg_8} -sort descending
create_multibit: Created a bus instance reg_bus_inst with instances in
 the order
reg_10 reg_9 reg_8 reg_7
```

See Also

- identify_multibit
- split_multibit

---

create_multisource_clock_sink_group

Defines sink groups for multisource clock tap assignment

Syntax

status *create_multisource_clock_sink_group*

```
-name name
-sinks pins_or_ports
[-driver_object pins_or_ports_or_nets ]
-type exclusive | non_exclusive
```

Feedback

Data Types

name	string
pins_or_ports	collection
pins_or_ports_or_nets	collection

Arguments

`-name` *name*

Specifies a name for the sink group. This option is required. The name can be used to refer to the sink group for reporting, removal, or modifications. Names have to be unique for all defined sink groups.

`-sinks` *pins_or_ports*

Specifies a list of clock sinks that should get assigned to the same tap driver as specified with the *-driver_object* option. If the *-driver_object* option is not specified the tool will assign the sinks to the closest tap driver available. A sink can only be assigned once to a sink group. Trying to assign a sink to multiple sink groups results in an error. The clock sinks have to be endpoints of the clock that gets assigned to the driver object using the *set_multisource_clock_tap_options* command.

`-driver_object` *pins_or_ports_or_nets*

This optional option specifies a driver object to which the sinks shall get assigned during tap assignment using the *synthesize_multisource_clock_taps* command. A driver object can either be a pin or port. If a net name is used, then the driver pin or port of that net is inferred as the driver object. Without using this option the group of sinks is assigned to the closest available tap driver.

`-type exclusive | non_exclusive`

Specifies the type of the sink group. The type can be either exclusive or non_exclusive. Exclusive means that no other sink which is not in that sink group can be assigned to the tap driver of that sink group. A non-exclusive sink group allows other sinks to get assigned to the tap driver of the sink group as well.

Description

The *create_multisource_clock_sink_group* command is used to define clock sinks to tap drivers. The assignment itself and the required netlist modifications are performed using the *synthesize_multisource_clock_taps* command. The sink group definition will only take effect if the driver object has also been assigned to a clock using the *set_multisource_clock_tap_options* command. Multiple sink groups can be assigned to the same driver object as long as they are non-exclusive.

An error is issued if a particular sink group with the given name has already been defined.

Feedback

The *remove_multisource_clock_sink_groups* command can be used to remove sink groups that have been created with this command.

The *report_multisource_clock_sink_groups* command can be used to report sink groups created with this command.

The *get_multisource_clock_sink_groups* command can be used to obtain a collection of sink groups.

The *add_to_multisource_clock_sink_group* command can be used to add additional sinks to an existing sink group.

The *remove_from_multisource_clock_sink_group* command can be used to remove sinks from an existing sink group.

Attributes

Four attributes are defined on sink groups:

- name: a read-only attribute that returns the name of a sink group.
- sinks: a read-only attribute that returns the collection of sinks of a sink group.
- type: attribute that corresponds to the type (exclusive or non-exclusive) of a sink group. The attribute is read-write.
- driver_object: The driver of the sink group. The attribute is read-write.

The *get_attribute*, *set_attribute*, and *report_attributes* commands can be used to access these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific, mode-specific, or corner-specific information.

Examples

This example creates an exclusive sink group of two sinks.

```
create_multisource_clock_sink_group -name sink_group1
 -type exclusive
 -driver_object [get_pins {tap_driver1/Z}]
 -sinks [get_pins {reg1/CK reg2/CK}]
```

This example creates a non-exclusive sink group.

```
prompt> create_multisource_clock_sink_group -name sink_group1 \\
   -type non_exclusive \\
   -driver_object [get_pins {tap_driver2/Z}] \\
   -sinks [get_pins {reg*/CK}]
```

Feedback

This example creates a non-exclusive sink group without an explicit driver object.

```
prompt> create_multisource_clock_sink_group -name sink_group1 \\
   -type non_exclusive \\
   -sinks [get_pins {reg*/CK}]
```

---

create_mv_cells

Creates power management cells including repeater, isolation and level shifter cells in the design based on UPF strategies.

Syntax

status *create_mv_cells*

```
[-isolation]
[-level_shifter]
[-retention]
[-repeater]
[-swap_fine_grain_cells]
[-map_ao_block]
[-mapped]
[-all]
[-always_on]
[-generate_strategy level_shifter]
[-strategy_output output_filename]
[-all_blocks | -blocks block_designs]
[-host_options host_option_name]
[-verbose]
```

Data Types

```
output_filename     string
block_designs       collection
host_option_name    string
```

Feedback

Arguments

`-isolation`

Inserts isolation cells in the design based on isolation strategy settings. If there is no user isolation strategy, isolation cells are not inserted. The tool automatically triggers repeater insertion based on repeater strategy settings.

`-level_shifter`

Inserts level shifter cells in the design based on level shifter strategy settings. The tool automatically triggers repeater insertion based on repeater strategy settings.

`-retention`

Inserts retention cells in the design based on retention strategy settings.

`-repeater`

Inserts repeater cells in the design base on repeater strategy settings. If this option is the only one set in the command, create_mv_cells will only insert repeater cells.

If any other PM cell option set in the command, repeater cells will also be inserted in the design. This is to provide insertion of repeater cell only if necessary, otherwise repeater cells will be inserted automatically along with other PM cells insertion.

`-swap_fine_grain_cells`

Swap none-fine-grain(no build in switch) cells to fine-grain(with build in switch) cells base on the power_switch strategy settings.

`-map_ao_block`

When the design has single rail cells without explicit connect_supply_net in always-on block domain, the tool remaps the cells into dual rail cells.

`-mapped`

By default, tool inserts new repeater, level shifter and isolation cells from GTECH library only. When -mapped option is specified, tool inserts new repeater, level shifter and isolation cells from user libraries only. Existing GTECH repeater, level shifter and isolation cells in the design are updated to user library cells.

`-all`

Inserts repeater, isolation and level shifter cells in the design based on repeater, isolation and level shifter strategy settings. When the design has single rail cells without explicit connect_supply_net in always-on block domain, the tool remaps such cells into dual rail cells.

Feedback

`-always_on`

Runs always-on legalization on the current design to convert illegal single-rail buffers or inverters into legal dual-rail counterparts, and vice-versa.

The *-always_on* argument is most effective when specified together with the *-level_shifter* argument, so that the command can fix isolation and voltage violations involving buffers or inverters at the same time. It can help to find solutions, which cannot be achieved by running the command with each option specified separately.

`-generate_strategy level_shifter`

If no level shifter strategy is loaded in the UPF, the tool can generate general level shifter strategies based on domain supply voltage shifting status. If there is no voltage shifting among all domain supplies, no strategy is generated. The *-generate_strategy* option only supports the *level_shifter* keyword.

This option can be combined with the *-strategy_output* option. If *-strategy_output* specifies an output file, strategies generated are written out to the output file only and the tool does not perform level shifter cell insertion based on the strategy. If *-strategy_output* is not specified, the tool continues to do automatic level shifter insertion based on the strategy generated internally. The strategies can be written out in the UPF derived session.

`-strategy_output` *`output_filename`*

If the *-generate_strategy level_shifter* option is specified together with the *-strategy_output output_filename*, the tool generates general level shifter strategies based on domain supply voltage shifting status and writes out all strategies to the specified file. You can modify the strategies and reload them into the tool.

`-all_blocks`

Creates MV cells for all the child blocks in the current design and the current design itself. This option is mutually exclusive with *-blocks*. Only one of them can be specified at a time.

`-blocks` *`block_designs`*

Specifies the list of child block designs to create MV cells. This option is mutually exclusive with *-all_blocks*. Only one of them can be specified at a time.

`-host_options` *`host_option_name`*

Specifies the host option to use for distributed processing. If not specified, the tool uses the global host option if the option contains a distributed processing settings.

Feedback

`-verbose`

Prints out additional debug messages when inserting power management cells. Currently, the verbose messages only include debugging information for level shifter cell insertion.

Description

This command creates power management cells in the design based on UPF strategies.

In addition, this command applies optimization restrictions (dont_touch) on the nets between isolation, level shifter, repeaters cells and their corresponding power domain boundaries. Buffers might be inserted on these nets to prevent them from being over constrained.

Examples

The following example inserts repeater, isolation and level shifter cells in the design based on UPF strategies:

```
prompt> create_mv_cells -all
Information: Total 20 repeater cells have been inserted. (MV-054)
Information: Total 51 isolation cells have been inserted. (MV-054)
Information: Total 51 isolation cells have been associated. (MV-021)
Information: Total 30 level shifter cells have been inserted. (MV-054)
Information: Total 0 MV restriction buffer cells have been inserted.
 (MV-054)
Information: Total 1 fine grain power switch cells have been swapped.
 (MV-054b)
1
```

---

create_net

Creates one or more power, ground, tie, or signal nets.

Syntax

collection *create_net*

```
[-design design]
[-power | -ground | -tie_high | -tie_low]
[-cell cell]
net_names
```

Data Types

design	collection
cell	collection
net_names	list

Arguments

`-design` *design*

Specifies the design in which to create the nets. If no design is specified, the nets are created in the current design.

`-power`

Specifies that power nets should be created.

`-ground`

Specifies that ground nets should be created.

`-tie_high`

Specifies that tie-high nets should be created.

`-tie_low`

Specifies that tie-low nets show be created.

net_names

Specifies the names of the nets to be created in the design. Each net name must be unique.

Feedback

`-cell` *cell*

Specifies the cell where the net is to be added. The net is created in the cell's reference module. The cell must not reference a library cell, unless this command is executed in the library manager. In the library manager, nets might be created in library cells. When not specified, the net is created in the current module.

Description

The *create_net* command creates new nets in the current design (unless otherwise specified by -design). It creates only scalar (single-bit) nets. One net is created for each of the names listed.

This command can create PG, tie, or signal nets. If no net type is specified, the command creates signal nets.

Nets connect ports and pins in a design. The *create_net* command creates nets, but does not connect the nets. To establish this connection, use the *connect_net* or *connect_pg_net* commands.

Examples

The following example creates signal nets named *N1*, *N2*, *N3*, and *N4*.

```
prompt> create_net {N1 N2 N3 N4}
```

The following example creates a power net named *VDD*.

```
prompt> create_net -power VDD
```

---

create_net_bus

Creates a net bus.

Syntax

collection *create_net_bus*

```
[-design design]
[-block block]
```

Feedback

```
[-cell cell]
[-create_nets]
net_bus_name
```

Data Types

```
design          collection
block           collection
cell            collection
net_bus_name    string
```

Arguments

`-design design`

Specifies the top-level design for finding objects. If this is not specified, objects are found in the current design.

`-block block`

Specifies the block where the net bus is to be added. If specified, *create_net_bus* has the same effect as *edit_module* in which the module is changed and changes are applied to all module occurrences.

`-cell cell`

Specifies the cell where the net bus is to be added. The net bus is created on the cell's reference module. *create_net_bus* first uniquifies the reference if needed, then creates the net bus. When not specified, the net bus is created on the current module.

`-create_nets`

Creates net bus members if they do not exist.

`net_bus_name`

Specifies the net bus name and its range using the *name [start: end]* format. Specify a net bus named busA with net from 1 *to* 5 as *busA[1:5]*. Specify a net bus named busB with net from 5 *downto* as *busB [5:1]*.

Description

This command creates a net bus, collects or creates net bus members, and puts them into the net bus created.This supports creating n-dimensional bus.

The command returns the created net_bus(as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

Examples

The following example creates net bus named *bus1* from net 1 to 5 as bus[1], bus[2], bus[3], bus[4], bus[5]

Feedback

```
prompt> create_net_bus bus1[1:5]
{"bus1"}
```

The following example first creates nets, then creates a net bus named *bus2* from the created net with indexes 5 downto 1 as bus2[5], bus2[4], bus2[3], bus2[2], bus2[1]

```
prompt> create_net_bus bus2[5:1] -create_nets
{"bus2"}
```

See Also

---

create_net_priority

Creates an analog constraint group with net_priority intent in the current design.

Syntax

collection *create_net_priority*

```
[constraint_group_name]
-for objects
[-priority int]
[-force]
```

Data Types

constraint_group_name	string
objects	collection
int	integer

Arguments

constraint_group_name

Specifies the name of the constraint group. If not specified then a system generated name is assigned.

-for *objects*

Specifies the objects - can be nets, bundles, or topology_edges - that constitute the analog constraint group. It can be specified as a string (name of objects) or the collection of objects.

Feedback

`-priority int`

Specifies the priority of routing for the constituent objects. Objects with higher priority will be routed first. Priority values can be given from -128 to 128. Default is zero.

`-force`

Specifies force deletion of existing constraint group by the same name as specified and recreation of new constraint group. Default is false where the command exits with error if same name is encountered.

Description

The *create_net_priority* command enables you to create a constraint group for a collection of nets, bundles, and topology_edges with net_priority intent. The constraint is used by Custom Router. All the constituent objects will be routed with same priority and will be routed before other objects that have lower priority.

Examples

The following example creates a constraint group named 'abc' for nets and bundles matching the pattern 'pr*' with net_priority intent and priority of 15. The 'pr*' nets are routed with Custom Router.

prompt> *create_net_priority abc -for pr* -priority 15 {abc}*

---

create_net_shielding

Creates an analog constraint group with shielding intent in the current block.

Syntax

collection *create_net_shielding*

```
[constraint_group_name]
-for objects
[-shield_net net]
[-shield_net_2 net]
[-gap distance]
[-width distance]
[-max_gap distance]
[-min_segment distance]
```

Feedback

```
[-sharing true | false | unset]
[-enclose_pins true | false | unset]
[-enclose_vias true | false | unset]
[-via_defs via_defs]
[-disabled_layers layers]
[-layer_widths widths]
[-layer_gaps gaps]
[-layer_max_gaps gaps]
[-group_shield]
[-force]
```

Data Types

constraint_group_name	string
objects	collection
net	collection
distance	float
via_defs	string
layers	string
widths	list
gaps	list

Arguments

constraint_group_name

Specifies the name of the constraint group.

By default, the command generates a unique constraint group named shielding_*n*, where *n* is a unique, monotonically increasing integer value.

-for *objects*

Specifies the objects that constitute the analog constraint group. The objects can be nets, bundles, or topology_edges. You can specify the objects as a list of object names or as a collection of objects.

-shield_net *net*

Specifies the net to connect to shield material. For single signal routing, the tool uses this net for the left and bottom shields.

-shield_net_2 *net*

Specifies the net to connect to secondary shield. For single signal routing, the tool uses this net for the top and right shields.

-gap *distance*

Specifies the layer-independent spacing between route objects and shield objects.

The default is 0.

Feedback

`-width` *distance*

Specifies the layer-independent width for shielding material.

The default is 0.

`-max_gap` *distance*

Specifies the layer-independent maximum spacing between route objects and shield objects.

The default is 0.

`-min_segment` *distance*

Specifies the minimum length of wiring to shield.

The default is 0.

`-sharing true | false | unset`

Specifies whether shielding can be shared between constituent objects of the constraint group.

Allowed values are *false*, *true*, and *unset*.

The default is *unset*.

`-enclose_pins true | false | unset`

Specifies whether pins are enclosed by the shield. This option is mutually exclusive with *-group_shield* option.

Allowed values are *false*, *true*, and *unset*.

The default is *unset*.

`-enclose_vias true | false | unset`

Specifies whether vias are enclosed by the shield.

Allowed values are *false*, *true*, and *unset*.

The default is *unset*.

`-via_defs` *via_defs*

Specifies the via definition names to be used to connect to the shield.

By default, all via definitions can be used.

`-disabled_layers` *layers*

Specifies the layer names that are not to be used for shielding.

Feedback

`-layer_widths` *widths*

Specifies the width of a layer used for shielding.

This is a list of alternating layer and width values, where the layer is a string and the width is a floating point number. For example, {M1 5.0 M2 6.0}.

`-layer_gaps` *gaps*

Specifies the gap of shielding material from wiring material.

This is a list of alternating layer and gap values, where the layer is a string and the gap is a floating point number. For example, {M1 5.0 M2 6.0}.

`-layer_max_gaps` *gaps*

Specifies the maximum gap of shielding material from wiring material.

This is a list of alternating layer and maximum gap values, where the layer is a string and the maximum gap is a floating point number. For example, {M1 5.0 M2 6.0}.

`-group_shield`

Specifies whether a single set of shield shapes can be used to shield all nets of the constraint group. This option is mutually exclusive with *-enclose_pins* option.

`-force`

Forces the deletion of an existing constraint group if the name matches the specified *constraint_group_name* argument.

By default, the command exits with an error if the name already exists.

Description

Some signal nets require isolation or shielding to allow the circuit to function correctly. Whether it is to reduce crosstalk or parasitic effects, some nets must be shielded.

The *create_net_shielding* command creates a constraint group for a collection of nets, bundles, and topology_edges with shielding intent to achieve the necessary shielding. The constraint is used by the Custom Router tool.

Each of the constituent objects are shielded separately as per the requirements specified in the constraint group. Use this constraint to specify which layers to constrain and any layer-specific requirements.

Examples

The following example creates a constraint group with a system-generated name that describes the shielding intent for nets whose name starts with "pr". A gap of 3 is used for the M2 layer and a gap of 5 is used for the M3 layer. All constituent objects can share the

Feedback

shield and the M5 and M6 layers cannot be used for shielding. The 'pr*' nets are routed with the Custom Router tool.

```
prompt> create_net_shielding -for pr* -disabled_layers {M5 M6} \\
   -sharing true -layer_gaps {M2 3 M3 5}
{shielding_4}
```

---

create_new_function_lib_cells

Create one or more lib_cells for a brand new function.

Syntax

status *create_new_function_lib_cells*

```
-base_name   lib_cell_name_string_list
-analysis    analysis_name
-libset      libset_name
-suggestion_library lib
[-name_prefix string]
[-name_suffix string]
[-exact_names lib_cell_name_string_list]
[-function equation_string]
[-design design]
[-nf_names new_function_name_string_list]
[-family_target string]
[-lib_cell_targets lib_cells]
[-drives drive strength list]
```

Data Types

```
lib_cell_name_string_list  list-of-strings
analysis_name string
equation_string string
libset_name  string
new_function_name_string_list  list-of-strings
cost_name_string  string
cost_percent  float
drive_strength_list  list-of-ints
```

Feedback

Arguments

`-base_name`

The base name for the new lib cell being created. For example if you are creating new five-input XOR gate(s), you might choose 'XOR5' as the base name for the new lib cell(s). The name of new lib cell name is constructed by name_prefix + base_name + drive_name + name_suffix.

`-analysis`

The analysis layer created by run_library_analysis whose data will be used to construct timing estimation models for the new lib cells being built.

`-libset`

The libset in which the new suggestion library will be created

`-suggestion_library`

The suggestion library to store the new lib cell(s).

`-name_prefix`

The name prefix for the new lib cell being created. The name of new lib cell is constructed by name_prefix + base_name + name_suffix.

`-name_suffix`

The name suffix for the new lib cell being created. The name of new lib cell is constructed by name_prefix + base_name + name_suffix.

`-exact_names`

To overrides auto-generated name. You can use it to directly give the name to new lib cell(s).

`-function`

A logical equation string for the new function to be created. For example, -function "Y=A^B^C^D" would describe a four input XOR gate which has inputs A, B, C and D, and output Y.

`-design`

A linked design in memory which represents the single output combinational function that will be built for this lib cell. The netlist must be mapped into primitive library cells from the reference library, and must have (currently) less than or equal to eight inputs.

`-nf_names`

If you have run design-driven analysis prior to this command, you will see new functions added into Libra. They will be named "nf0," "nf1," and so on. You can supply a list of the 'new function' names as the argument which describes what

Feedback

functions to implement. For example, "-nf_name nf22" will use "nf22" as the input for new function creation. More than one name can be given.

`-family_target`

"Target" lib cells describe what types of gates you want this command to build. So, for example, if you have a family of lib cells containing ND2X2, ND2X4, and ND2X8 named "myND2s" then using the argument -family_target myND2s will build you three new lib cells that most closely match to those gates.

`-lib_cell_targets`

"Target" lib cells describe what types of gates you want this command to build. So, for example, if you have a collection of lib cells containing INVX2, INVX4, and INVX8 then using -lib_cell_targets [get_lib_cells libA/INVX2 libA/INVX4 libA/INVX8] will build you three new lib cells that most closely match to those gates' properties. The tool looks into the electrical properties of the given "Target" lib cell, trying to estimate its drive strength and later builds a new lib cell with the similar drive strength. For a better estimation result, it is suggested to use simpler "Target" lib cells like inverter or buffer cells.

`-drives`

In some cases, this command may not be able to properly guess the drive strength of the lib cell targets supplied by -lib_cell_targets. This optional option allows you to override the internal 'guess' for target libcell drive strengths, and specifically indicate the drive strengths (as integers) that you want to create. The number of entries in this list must match the number of lib cell targets given by the -lib_cell_targets option.

Description

This command will create a new lib cell or set of new lib cells given the logic function description of the gate. You can specify the logic function using one of -function, -design, or -nf_name. You specify the prefix name for the new library cell using -name_prefix, and the analysis layer from which cell models are derived by using -analysis. The libset from which target lib cells and modeling data are collected is given with -libset. In addition, you have to tell the command how many lib cells to build for this new function. The way you do that is by giving the command 'targets'. "Target" lib cells describe what types of gates you want this command to build. So, for example, if you give a set of target lib cells containing ND2X2, ND2X4, and ND2X8, the command will try to build you an X2, X4, and X8 version of your new function.

Drive is the parameter that the mapping tries to match most closely from the targets, but it also tries to match delay, and following that, it tries to match area, leakage and internal power. You can direct a different weighting using the -*_coefficient arguments.

Feedback

You can also direct the command to not bother constructing a new lib cell if it cannot improve on the target lib cell by various amounts in various categories. The -cost_check and -cost_percent arguments help you do that level of checking.

Finally, there is the '-model_effort' switch which allows you to override the amount of work spent estimating the parameters. Imagine that you have a Nand-tree implementation of an AO22 gate, and you want to create that as a new lib cell to compare against the existing AO22 from the library. The question you have to answer first is "how much optimization do I want Libra to do?" By default we will refactor that netlist's logic, do sizing, and come up with a range of options for the new gate, considering them according to the costs that we've already described. But perhaps you have instead given us a netlist where you have a good idea of the structure already. In that case, use "low" as the effort setting. Instead, perhaps you have given us the exact netlist that you want, with precisely the given set of gate sizes that you want in the model. In that case, you would use "none" as the effort setting. So, an interesting experiment might be to do -model_effort none and -cost_check delay -cost_check 95.0, using a comparison AO22 gate as the target lib cell. In that case, this command will create a new lib cell if it is 5% or more better for delay as compared to the AO22 in the library. You can adjust the cost check parameters to define the level of checking you want to do against the target lib cells, and so this command will help you compare existing lib cells against netlist models that you have created.

Examples of using the command:

```
## It is suggested to use simpler "Target" lib cells like inverter or
 buffer cells, for better electrical property estimations.
create_new_function_lib_cells -name_prefix myXOR4 -function "Y=A^B^C^D"
 -lib_cell_targets [get_lib_cells libA/INVX*] -libset foo -analysis bar

create_new_function_lib_cells -name_prefix myOAI23 -design top
 -lib_cell_targets [get_lib_cells libB/INVX1 libB/INVX4] -libset foo
 -analysis bar

create_new_function_lib_cells -name_prefix myGate -nf_name nf1
 -lib_cell_targets [get_lib_cells libC/ND2*] -libset foo -analysis bar
```

create_package_statement

Creates 1 RTL package statement.

Syntax

collection *create_package_statement*

```
[-name name]
[-scope scope]
```

Feedback

Data Types

```
name        string
scope       collection
```

Arguments

`-name` *name*

Specifies the name for the package statement.

`-scope` *scope*

Adds the newly created package statement in the scope provided by the RTL statement.

Description

This command creates an RTL package statement. The package statement is created in the current instance.

Examples

The following example creates 1 package statement in the current instance.

```
prompt> create_package_statement \\
        {"RTL_PACKAGE_85"}
```

See Also

- get_statements
- remove_statements

---

create_pad_rings

Creates pad rings with simplified options control.

Syntax

status *create_pad_rings*

```
[-create create_opt]
[-nets netname_list]
-route_pins_on_layer layer_opt
[-min_target_layer layer_opt]
[-max_target_layer layer_opt]
[-drc drc_opt]
[-sides side_opt]
[-undo]
```

Feedback

Data Types

create_opt	specification
netname_list	list
layer_opt	specification
drc_opt	specification
side_opt	specification

Arguments

`-create all | pg | specified_net`

Creates pad rings for all pad pins, all pg pins, or pins with the specified nets. If the *-nets* options is specified, *all* and *pg* will be ignored. This argument is optional.

`-nets` *`netname_list`*

Specifies a list of nets on which to create pad rings. This argument is optional.

`-route_pins_on_layer` *`layer_opt`*

Creates pad rings on the specified metal layers. This argument is required.

`-min_target_layer` *`layer_opt`*

Specifies the lowest metal layer to create via for. This argument is optional.

`-max_target_layer` *`layer_opt`*

Specifies the highest metal layer to create via for. This argument is optional.

`-drc no_check | check_but_no_fix`

Specifies the DRC option for PG pad ring creation. The argument following *-drc* must be either *no_check* or *check_but_no_fix*. *no_check* specifies that no DRC check is performed. *check_but_no_fix* specifies that DRC check is performed and DRC errors are reported, but no DRC fixing is performed. By default, DRC is checked and fixed for the PG pad ring creation.

`-sides` *`side_opt`*

Specifies the side option for PG pad ring creation to support connections on aligned pins between neighboring pad cells. The syntax of the *side_opt* argument is *{{side start end} {side start end} ...}* where *side* is one of the following keywords: *left*|*right*|*top*|*bottom*. For *left* and *right* sides, the connection will be vertical and for *top* and *bottom* sides the connection will be horizontal. *start* and *end* denote the coordinate ranges to search for pad cells. It can be inside the core area as well. For *left* and *right* sides they are x coordinates and y for *top* and *bottom* sides.

Feedback

`-undo`

Removes pad rings and corresponding vias created by this command and restores the shapes to their original condition before running the *create_pad_rings* command.

Description

This command creates PG pad rings and provides a simple user interface. This command automatically calculates the required information to create pad rings and provides a simpler user interface than the *create_pg_ring_pattern* command.

Examples

The following example performs PG pad ring creation on metal layer M8 for all PG nets.

```
prompt> create_pad_rings -create pg -route_pins_on_layer {M8}
```

The following command performs PG pad ring creation on metal layer M8 for nets VDD and VSS without checking for DRC violations.

```
prompt> create_pad_rings -nets {VDD VSS} \\
    -route_pins_on_layer {M8} -drc no_check
```

The following command connects horizontally aligned pins of adjacent pad cells whose y coordinates fall between 0um and 700 um and between 1000um and 1700um.

```
prompt> create_pad_rings -create all  \\
    -route_pins_on_layer {M4 M5} -sides {{bottom 0 700} {top 1000 1700}}
```

Feedback

create_parameter_statement

Creates 1 RTL parameter statement.

Syntax

collection *create_parameter_statement*

```
-expression expression
[-type type]
[-name name]
[-module module | -cell cell]
[-scope scope]
```

Data Types

expression	collection
type	string
name	string
module	collection
cell	collection
scope	collection

Arguments

`-expression` *expression*

Specifies the expression statement for the parameter statement.

`-type` *type*

Specifies the type for the parameter statement. The default type is std. The available values are std, local, or const.

`-name` *name*

Specifies the name used for the parameter statement.

`-module` *module*

Specifies the module to create the parameter statement in.This is mutually exclusive with -cell. If neither of -module and -cell is specified, then parameter statement is created in the current instance.

`-cell` *cell*

Specifies the cell to create the parameter statement in.This is mutually exclusive with -module.

`-scope` *scope*

Adds the newly created parameter statement in the scope provided by the RTL statement.

Feedback

Description

This command creates a parameter object representing a 'parameter' statement in RTL. The parameterstatement is created in the specified module or cell. If both -module and -cell are not specified, then parameter statement is created in the current instance.

Examples

The following example creates one parameter statement in the given instance with the expression named "RTL_EXPRESSION_8".

```
prompt > create_parameter_statement -expression [get_statements
 u1/u1/RTL_EXPRESSION_8] -cell u1/u1
{"u1/u1/RTL_PARAMETER_85"}
```

- remove_statements

---

create_pg_composite_pattern

Creates a power ground composite pattern. This composite pattern can be defined hierarchically based on low-level patterns such as the basic wire patterns, or other composite patterns.

The composite pattern can be instantiated in a design by the *set_pg_strategy* command to create a power ground mesh.

Syntax

status *create_pg_composite_pattern*

```
pattern_name
[-nets net_list]
[-parameters var_list]
-add_patterns pattern_expr
[-via_rule via_rule_spec]
```

Data Types

```
pattern_name        string
net_list            list
var_list            list
pattern_expr        specification
via_rule_spec       specification
```

Feedback

Arguments

pattern_name

Specifies the name of the composite pattern.

-nets *net_list*

Specifies power and ground net names used in this composite pattern. The net names are symbolic names and are mapped from net names specified from a high-level command, that is, either from the symbolic net names in another *create_pg_composite_pattern* command or from the real net names in the *set_pg_strategy* command.

The net mapping is by position. For example, the first net name in a high-level command maps to the first net name in the low-level command, the second net name in a high-level command maps to the second net name in the low-level command, and so on.

If this option is not specified, the list of nets from its high-level command is mapped to its low-level patterns in the same order. If the low-level patterns have different orders or net names, you must specify this option, and specify the order of net names in *-add_patterns* option. If net-based via rules are needed in this composite pattern, net names should also be provided using this option for filtering purpose.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and passed into the low-level patterns used by this composite pattern. This allows the pattern to be programmed and reused by specifying different parameters for different situations. Each parameter *var* in the list *var_list* is a string. The "@" character is used as a prefix keyword to evaluate the parameter, for example, *@var*. Refer to the example section for more details.

-add_patterns *pattern_expr*

Specifies the low-level patterns for this composite pattern. Each low-level pattern is either a wire pattern created by the *create_pg_wire_pattern* command, or a composite pattern created by the *create_pg_composite_pattern* command. The low-level pattern cannot be the current composite pattern or contain the current composite pattern as its low-level pattern, that is, you must not create a recursive definition. Each pattern is specified by a pattern expression *pattern_expr* in the following syntax:

```
{name: child_pattern_name}
{nets: sub_net_list}
{parameters: sub_var_list}
{offset: {x_offset y_offset}}
{pitch: {x_pitch y_pitch}}
{repeat {x_num y_num}}
```

Feedback

The *name* keyword followed by *child_pattern_name* specifies the low-level pattern name to add to the current composite pattern.

The *nets* keyword followed by *sub_net_list* specifies the net name list to map into the symbolic list of nets in *child_pattern_name*. Each net name in *sub_net_list* must be one of the net names specified in *-nets* in the current composite pattern. The index of the *i_th* net in *sub_net_list* is *i*. If not specified, the list of nets from the current composite pattern is used for mapping.

The *parameters* keyword followed by *sub_var_list* specifies the parameter list to pass into the low-level pattern *child_pattern_name*. Each parameter can be either a value, such as 0.5 for wire width, or a variable evaluation, such as "@w" for wire width. "w" should be a parameter specified in *-parameters* in the current composite pattern.

The *offset* keyword followed by {*x_offset y_offset*} specifies the horizontal and vertical offsets when applying the low-level pattern *child_pattern_name* in the current composite pattern. The offset is applied to the origin of the low-level pattern *child_pattern_name*. The offset value is relative to the current composite pattern origin. By default, the offset is 0 for both horizontal and vertical offsets, and the origin of low-level pattern is the same as the current composite pattern origin.

The *pitch* keyword followed by {*x_pitch y_pitch*} specifies the horizontal and vertical pitches when applying and repeating the low-level pattern *child_pattern_name* in the current composite pattern. The pitch is the distance between two adjacent low-level *child_pattern_name* patterns. By default, the pitch is 0 for both horizontal and vertical pitches and the low-level pattern is not repeated.

The *repeat* keyword followed by {*x_num y_num*} specifies the horizontal and vertical repeating numbers when duplicating the low-level pattern *child_pattern_name* in the current composite pattern. By default, the low-level pattern *child_pattern_name* is repeated horizontally and vertically by the specified pitches until the pattern reaches the routing area boundary.

You can specify multiple pattern expressions and separate them by curly brace pairs. For example, one pattern expression per low-level pattern is within a pair of curly braces. The index of the *i_th* low-level pattern added into this composite pattern is *i*.

`-via_rule` *`via_rule_spec`*

Specifies the via rule *via_rule_spec* between wires in this composite pattern. The via rule defines the intersection locations and the via at the locations. The rule will only apply between layers of composite pattern, but won't apply between layer of composite pattern and layer of other pattern. Users must define

Feedback

using set_pg_strategy_via_rule if control is needed between layer of composite pattern and layer of other pattern.

There are several methods to define the intersection locations in the *via_rule_spec* specification, where the syntax is defined as follows:

```
{intersection : all}       {via_def} |
{intersection : adjacent} {via_def} |
list_of_filter_rules
```

The first method is "{*intersection* : all}", where *intersection* is the keyword and *all* refers to all intersections between any two orthogonal wires on any different layer.

The second method is "{*intersection* : adjacent}", where *intersection* is the keyword and *adjacent* refers to all intersections between any two orthogonal wires only between adjacent layers.

The third method is to define the intersections based on two sets of wire shapes using *list_of_filter_rules*. The rules contain a list of filtering rules. Each filtering rule is defined inside a curly brace pair. The syntax of each filtering rule is as follows:

```
{{set_1}{filter_1}} {{set_2} {filter_2}} {via_def} |
{intersection : undefined} {via_def}
```

where *set_1* refers to the first set of wire shapes and *filter_1* refers to the filtering operations for this set. *set_2* and *filter_2* refer to the second set of wire shapes and the filtering operations for the second set, respectively. *set_1* or *set_2* is defined as below:

```
{pattern : pattern_name}
```

where *pattern* is the keyword and *pattern_name* refers to one of the low-level patterns added to the current composite pattern by the *-add_patterns* option.

You can perform filtering operations on the set of wire shapes to obtained a subset of shapes. The filters are *filter_1* and *filter_2* in the previous example. The filtering operation is defined as follows:

```
{net_id : n_id} |
{nets : net_list} {layers : layer_list}
  {width : {lower_w upper_w}
```

where *net_id* is the keyword and *n_id* refers to the ID of the specified low-level pattern. The index of the *i_th* net in *sub_net_list* is *i* when specifying the low-level pattern. The subset of wire shapes contains the wires with the specified *n_id*. Net ID is useful when there are multiple nets with the same names within the list of nets in the low-level pattern. Alternatively, *nets*, *layers*, *width* keywords can be used to specify the wire net names by *net_list*, wire layer names by

Feedback

layer_list, or a width range by {*lower_w upper_w*}. Only the wire shapes in the lower-level pattern which also satisfy the filtering categories form a subset of wire shapes. Here, *net_list* contains a list of net names, *layer_list* contains a list of layer names, and {*lower_w upper_w*} defines the lower and upper range of the wire width. By specifying two sets of wires by pattern names or pattern IDs and certain filtering operations by net IDs, net names, layer names or wire width ranges, the via locations are the intersections between these two sets of wire shapes. For those intersections which do not belong to any filtering rule, the via definition can be specified by

```
{intersection : undefined}{via_def}
```

where the *intersection* keyword followed by *undefined* refers to the remaining intersections which do not belong to any filtering rules. By default, the tool does not create vias at the intersections which do not belong to any filtering rules, unless specified. Multiple via filtering rules, such as intersection location and via definition, can be defined and separated by curly braces where each filter rule is in one curly brace pair.

With the intersection definition, the via specification {*via_def*} is in the following format:

```
{via_master : via_master_list}
```

where the *via_master* keyword followed by *via_master_list* specifies the list of via masters. Via masters include the via contact code defined in the technology file, or user-defined via cells. The *via_master* keyword followed by *via_rule_list* specifies a list of via master rules. Via master rules are defined by *set_pg_via_master_rule* command. *NIL* can be used as a keyword indicate that no via should be created. *default* can be used to describe the default vias in the specified location. For each specified intersection, vias are created based on the specified via masters or via master rules. If *NIL* is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection of orthogonal wires in different layers.

Description

Creates a power ground composite pattern. This composite pattern can be defined hierarchically based on other low-level patterns such as the basic wire patterns using *create_pg_wire_pattern*, or other composite patterns using this command.

The via rules can also be defined between any wire shapes in this composite pattern. Each via rule contains the intersection location and the via definition by via master or via cell.

Feedback

The composite pattern can be instantiated in a design by the *set_pg_strategy* command to create a power ground mesh.

Examples

The following example creates a composite pattern, checker_board, with one horizontal wire pattern hor_wire, one vertical wire pattern ver_wire, and the checker board via rule between two wire patterns. Note that net_id is used to specify the checker board via rule.

```
prompt> create_pg_composite_pattern checker_board -nets {VDD} \\
   -parameters {ver_layer hor_layer ver_width hor_width ver_pitch
 hor_pitch} \\
   -add_patterns { \\
      {{name:ver_wire}{nets: {VDD VDD}} \\
         {parameters: {@ver_layer @ver_width}}\\
         {pitch: {0 @ver_pitch}} } \\
      {{name:hor_wire}{nets: {VDD VDD}} \\
         {parameters: {@hor_layer @hor_width}}\\
         {pitch: {@hor_pitch 0}} } \\
   } \\
   -via_rule { \\
      {{{pattern: ver_wire}{net_id: 1}} \\
       {{pattern: hor_wire}{net_id: 1}}\\
          {via_master: default}} \\
      {{{pattern: ver_wire}{net_id: 2}}
       {{pattern: hor_wire}{net_id: 2}} \\
          {via_master: default}} \\
      {{{pattern: ver_wire}{net_id: 1}} \\
       {{pattern: hor_wire}{net_id: 2}} \\
          {via_master: NIL}} \\
      {{{pattern: ver_wire}{net_id: 2}} \\
       {{pattern: hor_wire}{net_id: 1}} \\
          {via_master: NIL}} \\
   }
```

The following example creates a composite pattern which contains wire pattern from layer M3 to M8, strap3, strap4, strap5, strap6 strap7 and strap8. The nets of the composite pattern is pwr and gnd, which are symbolic. The nets for each low-level wire pattern are in different order. The via rule is specified as adjacent, that is, the default via is created at each intersection between any orthogonal wires in adjacent layers.

```
prompt> create_pg_composite_pattern m3_to_m8 -nets {pwr gnd} \\
   -add_patterns { \\
      {{name:strap3}{nets:{gnd gnd pwr pwr}}{pitch:6.6} \\
         {offset:{1.02 0}}}\\
      {{name:strap4}{nets:{pwr gnd}}{pitch:{0 7.8}} \\
         {offset:{0 5.9}}} \\
      {{name:strap5}{nets:{gnd pwr}}{pitch:{6.6 0}} \\
         {offset:{1.8 0}}} \\
      {{name:strap6}{nets:{pwr gnd}}{pitch:{0 7.8}} \\
         {offset:{0 5.9}}} \\
      {{name:strap7}{nets:{gnd pwr}}{pitch:{14 0}}  \\
```

Feedback

```
         {offset:{1.8 0}}} \\
      {{name:strap8}{nets:{gnd pwr}}{pitch:{0 9.6}} \\
         {offset:{0 6.6}}} \\
   } \\
   -via_rule {{intersection: adjacent}{via_master: default}}
```

The following example creates a composite pattern composed of two wire patterns on layers M3 and M5. Vias with the via master Via_via35 are added between parallel wires M3 and M5.

```
set_pg_via_master_rule Via_via35 -contact_code {via3_CUST via4_CUST} \\
   -via_array_dimension {2 1} \
   -allow_multiple {2.508 0.48} -cut_spacing {0.054 0.090}
create_pg_wire_pattern pg_wire -layer @l -direction @d -width @w \\
   -pitch @p -spacing @s -parameters {l d w p s}
create_pg_composite_pattern pg_pat -nets VSS \\
   -add_patterns { \\
      {{pattern: pg_wire} {nets: VSS}
         {parameters: {M3 vertical {0.19 } 2.508 interleaving}}
         {offset: 02.508}} \\
      {{pattern: pg_wire} {nets: VSS} \\
         {parameters: {M5 vertical {0.23 } 2.508 interleaving}} \\
         {offset: 02.508}} \\
   } \\
   -via_rule { \\
      {{pattern_id: 1} {pattern_id: 2} \\
         {via_master: Via_via35} {between_parallel: true}} \\
         {{intersection: undefined} {via_master: NIL}} \\
   }
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: *gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"*.

create_pg_macro_conn_pattern

Creates a macro power ground connection pattern. Use the *set_pg_strategy* command to instantiate the pattern and connect macros to the power ground network.

Syntax

status *create_pg_macro_conn_pattern*

```
pattern_name
-pin_conn_type long_pin | ring_pin | scattered_pin
[-nets net_list]
[-parameters var_list]
[-direction horizontal | vertical | @var]
[-width width | {hor_width ver_width} | @var]
-layers layer_name | {hor_layer ver_layer} | @var
[-spacing minimum | interleaving | spacing |
          {hor_space ver_space} | @var]
[-pitch pitch | {hor_pitch ver_pitch} | @var]
[-number num | {hor_num ver_num} | @nvar]
[-excluded_pins pin_filter_spec]
[-via_rule via_rule_spec]
[-pin_layers layer_list | @var]
```

Data Types

```

Feedback

```
via_rule_spec       specification
layer_list          list of string
```

Arguments

pattern_name

Specifies the name of the macro pattern.

-pin_conn_type long_pin | ring_pin | scattered_pin

Specifies the macro pin and connection types. This is a required option and you must specify the *long_pin*, *ring_pin* or *scattered_pin* keyword. The long_pin keyword refers to long pins in the macro; orthogonal straps will be created for connection. The ring_pin keyword refers to internal ring pins inside the macro; finger connections will be created to connect the ring pin to a strap or external macro ring in the external power network. The scattered_pin keyword refers to the irregular pin shapes scattered inside the macro; extension straps will be created to connect scattered pins to the external power network.

-nets *net_list*

Specifies power and ground net names used in this macro connection pattern. The net names are symbolic names and will be mapped from net names specified by using real net names in the *set_pg_strategy* command.

The net mapping is by position, that is, the *i_th* net name in *set_pg_strategy* command maps to the net name in the same position in this command. This option is not required and is needed when pin filtering based on net name is required. For example, use this option if certain nets can be skipped or pin connections in different nets have different via rules.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used by other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string and the at character (@) is used as a prefix to evaluate the parameter, such as @*var*. See the example section for more details.

-direction horizontal | vertical | @*var*

Specifies the direction of macro long pin connection straps. This option is required when you specify *-pin_conn_type long_pin*, otherwise, this option is ignored. This option specifies the direction for connection straps, not macro pins. The direction could be "horizontal", or "vertical", or specified by evaluating the variable *var* in the *-parameters* option. For parameters, the at character (@) is used as a prefix to evaluate the variable.

Feedback

`-width` *width* | {*hor_width ver_width*} | `@`*var*

Specifies the width of the macro pin connection straps. If you specify *-pin_conn_type long_pin*, only one width value is required. Otherwise, the horizontal width and vertical width must be specified with *hor_width* and *ver_width*, respectively. The unit is defined in the technology file.

The width can also be specified by evaluating the variable *var* in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum width defined in the technology file is used if this option is not specified.

`-layers` *layer_name* | {*hor_layer ver_layer*} | `@`*var*

Specifies the layer of the macro pin connection straps. This is a required option. If you specify *-pin_conn_type long_pin*, only one layer *layer_name* is required. Otherwise, the horizontal and vertical layers must be specified with *hor_layer* and *ver_layer*, respectively.

The layer names can be also specified by evaluating the variable *var* in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable.

`-spacing minimum | interleaving |` *value* | {*hor_space ver_space*} | `@`*var*

Specifies the spacing between macro connection straps in the pattern. This option only applies if you specify *-pin_conn_type long_pin* or *-pin_conn_type ring_pin*. If you specify *-pin_conn_type scattered_pin*, this option is ignored.

minimum keyword refers to the minimum spacing between connection straps defined in the technology file, based on the wire width. *interleaving* keyword means that the distance between adjacent center lines of connection straps is equal.

Specific values can also be used for spacing. If you specify *-pin_conn_type long_pin*, only one *value* is required. If you specify *-pin_conn_type ring_pin*, the horizontal and vertical spacing values must be specified with *hor_space* and *ver_space*, respectively.

The spacing can also be specified by evaluating the variable *var* in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum spacing is used if this option is not specified.

`-pitch` *pitch* | {*hor_pitch ver_pitch*} | `@`*var*

Specifies the pitch of macro connection straps in the pattern. The pitch only applies if you specify *-pin_conn_type long_pin* or *-pin_conn_type ring_pin*. If the connection type is *scattered_pin*, the pitch is ignored.

Feedback

If the connection type is *long_pin* or *ring_pin*, at least one of the *-pitch* or *-number* options must be specified. If both options are specified, both options are honored. Otherwise, one value is derived from another by evenly distributing the connection straps in the macro.

If the pin connection type is *long_pin*, one *value* must be specified for the pitch value. If the type is *ring_pin*, horizontal and vertical pitch values must be specified by *hor_pitch* and *ver_pitch*, respectively. The unit is defined in the technology file. The pitch values can also be specified by evaluating the variable *var* in the *-parameters* option. The at character (@) is used as a prefix to evaluate the variable.

`-number` *num* | {*hor_num ver_num*} | `@`*var*

Specifies the repeating number of macro connection straps in the pattern. It only applies if you specified *-pin_conn_type long_pin* or *-pin_conn_type ring_pin*. If the connection type is *scattered_pin*, the number is ignored.

If the connection type is *long_pin* or *ring_pin*, at least one of *-pitch* or *-number* option must be specified. If both are specified, both are honored. Otherwise, one value is derived from another by evenly distributing the connection straps in the macro.

If the pin connection type is *long_pin*, one *num* must be specified for the repeating pattern. If the type is *ring_pin*, horizontal and vertical numbers must be specified by *hor_num* and *ver_num*, respectively. The repeating number can also be specified by evaluating the variable *var* in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable.

`-excluded_pins` *pin_filter_spec*

This option is not required. This option only applies when you specify *-pin_conn_type scattered_pin*.

For *scattered_pin* connection type, certain pin shapes that satisfy the *pin_filter_spec* specification can be excluded for connection. The *pin_filter_spec* specification uses the following format:

{**layers** **:** *layer_list*}

where *layers* is the keyword for pin layers. *layer_list* is a list of strings which contains a list of layer names. The pin shapes which satisfy the above criteria are excluded from connection. By default, all pin shapes are connected if this option is not specified.

`-via_rule` *via_rule_spec*

Specifies the via rule *via_rule_spec* between connection straps and macro pins in this macro connection pattern. The via rule defines the intersection locations and the via at the locations.

Feedback

There are several ways to define the intersection locations in the specification *via_rule_spec*, where the syntax is defined as follows:

```
{intersection : all}       {via_def} |
{intersection : adjacent}  {via_def} |
list_of_filter_rules |
```

The first method is "{*intersection* : all}", where *intersection* is the keyword and *all* refers to all intersections between any two connection strap and macro pin across any layers.

The second method is "{*intersection* : adjacent}", where *intersection* is the keyword and *adjacent* refers to all intersections between any two connection strap and macro pin only in adjacent layers.

With the intersection definition, the via specification {*via_def*} uses the following format:

```
{via_master : via_master_list}
```

where *via_master* is the keyword for via masters including via contact code defined in the technology file or user-define via cells, or the PG via rules defined by *set_pg_via_master_rule* command. The *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or replication is needed, via rules specified by *set_pg_via_master_rule* command can be used. The *via_master_list* can also contain a list of PG via rules. *NIL* can be used as a keyword to indicate that no via is created. *default* can be used to describe the default vias in the specified location. If *NIL* is not specified in the list, the default contact code is used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file is created at each intersection of orthogonal connection straps and macro pins in different layers.

`-pin_layers` *layer_list* | *@var*

Specifies a list of layers for allowed pin connections. Only pins on the specified layers can be used for a PG connection. If not specified, pins on all layers will be considered for a PG connection.

Description

Creates a macro power ground connection pattern. This pattern can be instantiated in a design with the *set_pg_strategy* command to connect macros to the power ground network. There are three types of macro connections: *long_pin*, *ring_pin* and *scattered_pin*. This pattern can be also applied to power pad connection.

Feedback

Examples

The following example creates a macro connection pattern with long pin type. The pattern name is long_pin_pattern, the connection strap direction is horizontal, the layer is M5, symbolic net names are pwr and gnd respectively and width, spacing, pitch are specified through parameters w, s and p respectively. Default vias are created at all intersections between connection straps and macro pins.

```
prompt> create_pg_macro_conn_pattern long_pin_pattern \\
   -pin_conn_type long_pin -nets {pwr gnd} \\
   -direction horizontal -width @w \\
   -layers M5 -spacing @s -pitch @p \\
   -parameters {w s p}
```

The following example creates a macro connection pattern with ring pin type. The pattern name is ring_pin_pattern. The horizontal and vertical layers are M5 and M6 respectively. Width, spacing, pitch are specified by parameters.

```
prompt> create_pg_macro_conn_pattern ring_pin_pattern \\
   -pin_conn_type ring_pin \\
   -width {@hor_w @ver_w} -layers {M5 M6} \\
   -spacing {@hor_s @ver_s} -pitch {@hor_p @ver_p} \\
   -parameters {hor_w ver_w hor_s ver_s hor_p ver_p}
```

The following example creates a macro connection pattern with scattered pin connection type. The pattern name is scatter_pin_pattern. The connection strap width is specified with parameters. Horizontal and vertical layers are M5 and M6 respectively. Default vias are created between macro pins and connection straps.

```
prompt> create_pg_macro_conn_pattern scatter_pin_pattern \\
   -pin_conn_type scattered_pin -nets {pwr gnd} \\
   -width {@hor_w @ver_w} -layers {M5 M6} \\
   -parameters {hor_w ver_w}
```

---

create_pg_mesh_pattern

Creates a power ground mesh pattern. The mesh pattern can be instantiated in a design by *set_pg_strategy* command to create power ground mesh.

Syntax

status *create_pg_mesh_pattern*

```
pattern_name
-layers layer_expr
[-parameters var_list]
[-via_rule via_rule_spec]
```

Data Types

```
pattern_name        string
layer_expr          specification
var_list            list
via_rule_spec       specification
```

Arguments

pattern_name

Specifies the name of the mesh pattern.

-parameters *var_list*

Specifies the list of parameters. Each parameter can be evaluated and used by other options in this command. This allows the pattern to be programmable and reused by passing different parameters in different situations. Each parameter *var* in the list *var_list* is a string and the at character (@) is used as a prefix to evaluate the parameter, such as @*var*. See the example section for more details.

Feedback

`-layers` *layer_expr*

Specifies the layer configuration for this mesh pattern. Each layer is specified by a *layer_expr* expression in the following syntax:

```
{horizontal_layer | vertical_layer: layer_name | @var}
{width: minimum | value_list | @var}
{spacing: interleaving | minimum | value_list | @var}
{offset: offset_value | @var}
{pitch: pitch_value | @var}
{trim : true | false | @var}
{track_alignment : track | half_track | auto | @var}
{mask : mask_one | mask_two | mask_three |
 mask_one_mask_two_alternate |
   mask_two_mask_one_alternate | @var}
{mask_constraint : constraint_name}
```

where the specification contains several keywords, *horizontal_layer* or *vertical_layer*, *width*, *offset*, *pitch*, *spacing*, *trim*, *mask* and *mask_constraint*.

The *horizontal_layer* or *vertical_layer* keyword specifies the layer name for this layer. Only one of *horizontal_layer* and *vertical_layer* can be specified within one layer. The layer name is specified by *layer_name* or by evaluating the variable *var* in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable. The layer name is a required option in the layer spec.

The *width* keyword specifies the width of this layer. "minimum" refers to the minimum wire width defined in the technology file. *value_list* contains a list of width values, where the width value is a float-type value with units defined in the technology file. If the number of width values is smaller than the number of nets from the *set_pg_strategy* command, the last width value is assumed for the extra nets. The width can also be specified by evaluating the *var* variable in *-parameters* option. The at character (@) is used as a prefix to evaluate the variable. By default, the minimum width is used if this option is not specified.

The *offset* keyword specifies the offset value. *offset_value* is the offset applied to the center line of the first wire to the boundary of the routing region or a specified absolute coordinate in *set_pg_strategy* command. By default, the offset is 0. The offset can also be specified by evaluating the *var* variable in *-parameters* option.

The *pitch* keyword specifies the pitch value. *pitch_value* specifies the pitch of the wires in this layer. The pitch can also be specified by evaluating the *var* variable in *-parameters* option. This pitch is a required option in the layer spec.

The *spacing* keyword specifies the spacing between wires in this layer. *minimum* refers to the minimum spacing between wires defined in the technology file based on the wire width. *value_list* contains a list of spacing values, where the spacing value is a float-type value with unit defined in the technology file. Each

Feedback

spacing value specifies the spacing between the adjacent wires in the pattern. For example, the first spacing value specifies the spacing between the first and the second wires, and so on. The number of wires in this pattern is specified by the *set_pg_strategy* command. If the number of spacing values is smaller than the number of nets minus one, the last spacing value is assumed for the extra nets. *interleaving* keyword means that distance between adjacent center lines of wires is equal. The spacing can also be specified by evaluating the *var* variable in *-parameters* option. The at character (@) character is used as a prefix to evaluate the variable. By default, the minimum spacing is used if this option is not specified.

The *trim* keyword specifies the trim option for wires in this layer. Valid values are true, false or a value specified by evaluating the *var* variable in *-parameters* option. By default, the trim option is true.

The *track_alignment* keyword specifies the track alignment option for wires in this layer. The option can be track, half_track, or auto. When auto is specified, tool choose the alignment method with smaller number of used tracks. It can also be specified by evaluating the *var* variable in the *-parameters* option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are created at the specified location and no alignment is performed.

The *mask* keyword specifies the mask option for wires in this layer. The mask can be specified by one of the keywords, mask_one, mask_two, mask_three, mask_one_mask_two_alternate or mask_two_mask_one_alternate. It can also be specified by evaluating the *var* variable in the *-parameters* option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are not colored with mask if not specified.

The *mask_constraint* keyword specifies the mask constraint option for wires in this layer. The mask constraint is defined by the *set_pg_mask_constraint* command. It can also be specified by evaluating the *var* variable in the *-parameters* option. The at character (@) character is used as a prefix to evaluate the variable. By default, the wires are not checked against mask constraint.

Multiple layer expressions can be specified and separated by brace pairs, that is, one layer expression per layer is within a pair of braces.

`-via_rule` *`via_rule_spec`*

Specifies the *via_rule_spec* via rule between wires in this mesh pattern. The via rule defines the intersection locations and the via at the locations. The rule will only apply between layers of mesh pattern, but won't apply between layer of mesh pattern and layer of other pattern. You must define via rules with the *set_pg_strategy_via_rule* command if control is needed between layer of mesh pattern and layer of other pattern.

Feedback

There are several ways to define the intersection locations in the *via_rule_spec* specification, where the syntax is defined as follows:

```
{intersection : all}       {via_def} |
{intersection : adjacent}  {via_def} |
list_of_filter_rules |
```

The first method is "{*intersection* : all}", where *intersection* is the keyword and *all* refers to all intersections between any two orthogonal wires in any different layers.

The second method is "{*intersection* : adjacent}", where *intersection* is the keyword, and *adjacent* refers to all intersections between any two orthogonal wires only in adjacent layers.

The third method is to define the intersections based on two sets of wire shapes using *list_of_filter_rules*, which contains a list of filtering rule. Each filtering rule is inside a brace pair. The syntax of each filtering rule is as follows:

```
{filter_1}{filter_2}{via_def} |
{intersection : undefined}{via_def}
```

where *filter_1* refers to the first filtering operation and *filter_2* refer to the second filtering operation. The intersection is defined between the first set and second set of wires based on the filtering rules. The second filtering rule is optional, that is, the intersection is defined based on the first set of wires to all other wires in this mesh.

The filtering operation is defined as follows:

```
{layers : layer_list} {width : {lower_w upper_w}}
```

where the *layers* and *width* keywords can be used to specify the wire layer names by *layer_list* or width range by {*lower_w upper_w*}. Here, *layer_list* contains a list of layer names, and {*lower_w upper_w*} is the lower/upper range of wire width. For those intersections which do not belong to any filtering rule, the via definition can be specified as follows:

```
{intersection : undefined}{via_def}
```

where *intersection* is the keyword and *undefined* refers to the remaining intersections which do not belong to any filtering rules. By default, vias are only created at the intersections which belong to a filtering rule. Multiple via filtering rules for intersection location and via definition can be defined and separated by braces where each filter rule is in one brace pair.

With the intersection definition, the via specification {*via_def*} uses the following format:

```
{via_master : via_master_list | via_rule_list}
```

Feedback

where *via_master* is the keyword for via masters including via contact code defined in the technology file or user-defined via cells, The PG via rules defined by *set_pg_via_master_rule* command can be also specified in the list. *via_master_list* specifies the list of via masters. Via masters are created at the intersection center without replication. If offset or specific array dimension is needed, via rules specified by *set_pg_via_master_rule* command can be used. *via_rule_list* is a list of PG via rules. *NIL* can be used as a keyword indicate that no via would be created. *default* can be used to describe the default vias in the specified location. Multiple via rules can be specified and separated by brace pairs. If *NIL* is not specified in the list, default contact code will be used to complete a stacked via or to replace a via with DRCs when applicable.

By default, the default via defined in the technology file will be created at each intersection of orthogonal wires in different layers.

Description

Creates a power ground mesh pattern. This mesh pattern can be used to create PG mesh with the *set_pg_strategy* command.

The via rules can also be defined based on intersection or filtering rules. Each via rule contains the intersection location and the via definition by contact code or via master rule.

Examples

The following example creates a mesh pattern with three layers. Parameters are used for width and offset. The vias between adjacent layers are specified in the via rule. *set_pg_strategy* and *compile_pg* are used to create the mesh.

```
prompt> create_pg_mesh_pattern mesh \\
   -parameters {w1 w2 w3 f} \\
   -layers { \\
      {{vertical_layer: M8}{width: @w1} \\
          {spacing: interleaving}{pitch: 20} {offset: @f}} \\
      {{horizontal_layer: M7}{width: @w2} \\
          {spacing: interleaving} {pitch: 20} {offset: @f}} \\
      {{vertical_layer: M6}{width: @w3} \\
          {spacing: interleaving}{pitch: 20} {offset: @f}} \\
   } \\
   -via_rule { \\
      {{layers: M8}{layers: M7}{via_master: VIA78}} \\
      {{layers: M7}{layers: M6}{via_master: VIA67}} \\
   }

prompt> set_pg_strategy smesh \\
   -pattern { \\
      {pattern: mesh}{nets: VDD VSS} \\
          {parameters: 5 3 1 3}} \\
   -core
```

Feedback

```
prompt> compile_pg

The following example creates a mesh pattern with layers with same
 direction.
Parameters are used for width and offset. The vias between parallel
layers M8 and M6 are specified in the via rule.

prompt> create_pg_mesh_pattern mesh \\
   -parameters {w1 w3 f} \\
   -layers { \\
      {{vertical_layer: M8}{width: @w1} \\
          {spacing: interleaving}{pitch: 20} {offset: @f}} \\
      {{vertical_layer: M6}{width: @w3} \\
          {spacing: interleaving}{pitch: 20} {offset: @f}} \\
   } \\
   -via_rule { \\
      {{layers: M8}{layers: M6} \\
         {via_master: VIA78 VIA67}{between_parallel: true}} \\
   }
```

In addition to the above examples, see the Examples page in the PG Planning section of the Task Assistant for more information. To view the Examples page, start the GUI and invoke the following command: *gui_show_task_assistant -task "Design Planning:PG Planning->Examples->Overview"*.

Feedback

create_pg_ml_data

Create ML training files based on created ML training data in memory.

Syntax

status *create_pg_ml_data*

```
[-output_directory directory_name]
```

Data Types

```
directory_name        string
```

Arguments

`-output_directory` *directory_name*

Specify directory name for created ML training file. The option is required.

Description

This command creates ML training files based on created ML training data in memory.

Examples
